INDEX TO VOLUME XVI.

(Abbreviations: * Illustrated; c Correspondence.)

A

Accidents: on German Street Railways [Vellguth] 1046
——Instructions in Ithaca..... 774
——Methods Employed in Handling Them [Patterson] 876
——Methods in Boston [Baxter]..... 1200
——Unique in Milwaukee..... 773
Accountants' Association, Street Railway, Kansas City Convention:
—— Brief Report of..... 1032
—— Notes and Comments on [Kittredge] 1070, 1173
—— Papers at 1081
—— Report of Secretary and Treasurer.... 1079
—— Report on Standard Accounting System 1083
—— President's Address 1077
—— Programme of 898
——Officers and Executive Committee of..... *954
Accounting Department, Its Relation to the General Manager [Beggs]..... 1081
Advertising, Car, Striking..... 850
Akron, New Power Station in..... 900
Albany, Drying Motors in,..... *146
Albany & Hudson Railway, Opening of..... 1183
Aluminum, Use for Feeders..... 126
—— [Perrine and Baum]..... 512
America's Contribution to Electric Railways. 951
American Bridge Company, Organization of.. 760
American Engineers and Tramway Managers Abroad 989
American Railways Company, Annual Report of 905
American Street Railway Association, Editorial on 1069
——Kansas City Convention, Attendance at.. 1095
—— Brief Report of..... 1031
—— Entertainments at..... 1061
—— Exhibits at *1097
—— Hotel and Exhibition Arrangements for 278
—— Officers and Executive Committee.... *953
—— Papers at 1188
—— Plan of Convention Hall..... *855
—— Proceedings of 1051
—— Programme of 238
—— Special Train to..... 1033
Amusements for Parks and Pleasure Resorts, *267, *380
Armatures, Repair-Shop Methods at Council Bluffs 1179
——(See also Testing Motors.)
Arnold System of Power Transmission..... *161
Artificial Stone, Method of Making..... 541
Atlanta, Home-Built Car in..... *375
——Legal Controversy in 1194
Augusta, Ga., Accounting System in [Simpson] 1084
Australia, Electric Tramways in Perth..... *336
Automobiles Operated by Trolley..... 306

B

Babbitt and Bronze, Deoxidized..... 566
Baggage, Right to Carry in Massachusetts.. 490
Baltimore, School for Motormen in..... 393
——United Railways & Electric Company, Indebtedness of 414
Baltimore & Ohio Tunnel, Third Rail in..... 639
Barcelona, Electric Railways in..... 1215
Baxter, Charles S..... *1204
Belgium, Report of National Railway Company 539
Berlin: Elevated Electric Railroad..... *980
——Grosse Berliner Strassenbahn, System of. *619
——Stadtbahn, Proposed Electric Equipment of *152
——Storage Battery Cars in..... 1157
——Strike in 675
——Wannseebahn, Trials on..... 796
——(See also Notes from Germany.)
Birmingham, Ala.: Consolidation in..... 1128
——Railway System of..... *528
Block Signal Systems: in Colorado Springs.. *483
——for Grade Crossings..... *1008
——in Lowell *164
——New (U. S. E. S. Co.)..... *1026
Boiler Compounds (Lord)..... 379
Boiler Tube Cleaner (Weiland)..... *755
Boosters Used in Brooklyn [Russell]..... 293
Boston to New Castle, Del., Trolley Trip.... c 540
Boston: Elevated Railway Drawbridge..... *37
——Methods of Claim Department [Baxter].. 1200
——Snow Plows in..... *477
——Suburban Company to Enter..... 1214
——System of Accounts in [Wilson]..... 1086
——Tests of Train Unit Systems in.....395, *440
——Vestibules Proposed in..... 1048
Brakes: Paper on [Fromm and Poetz]..... 1046
——Paper on [Monmerqué]..... 1160
——Test of, by New York State Commissioners 682
Brakes, Air: (Knell)..... *1013
——Brake, Neal-Jupiter *753
——Instruction Book on (Christensen)..... 1191
Brakes, Mechanical: Track and Wheel (Rote) *1010
——Price Friction *1021
Brake Handles, Ratchet (Beverly)..... *1020
Brazil, Sao Paulo, Railway System of..... *825
——Opening of *658
Breaking of Copper Trolley Wire.....c *820
Breed, A. F..... 570
Bridge: Elevated in Boston..... *37
——70-ft. Draw in Bergen County..... *116
British Westinghouse Company, Annual Report of 1206
Brockton, Consolidation in..... *1128
Brooklyn Rapid Transit: Annual Report of.784, 1211
——Collecting Fares on..... 766
——the Congested Problem of..... *31
——Elevated Cars for (Brill)..... *1189
——Electrolytic Corrosion in [Sheldon]..... 514
——Increase of Wages in..... 59
——Operation of Sea Beach Route [Russell]. *293
——Repair Shops of..... *1143
——Ridgewood Station, Destroyed by Fire.. 1197
——System of Accounts [Barnaby]..... 1088
——Taxation of Franchises [Williams]..... 1138
——Visit of Japanese Railroad Officials to.... *667
Buffalo: Electrical Welding of Joints in..... *25
——Open Car for..... *653
——Pan-American Exposition Buildings..... *44
——Rotary Converters in [Danforth]..... 902
——Snow and Snow Plows in [Danforth].... 1035
——Storage Batteries in [Henning]..... *901
——Tests of Power Plant [Carpenter and Ryan] 676
——Tests of Storage Batteries in [Norris].... 892
——Use of Niagara Power for Railways in.. *103
Burlington, Ia., Notes from..... *536

C

Cable Railways, Change to Electric: in Denver 384
——in New York *830
Calcutta, Electrical Business in..... 1202
Camden: Cost of Painting Cars in [Harrington] 1076
——Employees' Club Organized at..... 662
——Watt-Hours per Car Mile in [Harrington] 1056
Canada, Electric Railways in..... 781
Cape Town, Car for..... *1007
Car Bodies, Painting and Repainting [Brydges] 1076
——Cost of Painting in Camden [Harrington] 1076
Car Building [Davis].....*143, *250, *360, *453, *549 *639, *731, *831, *993, *1175
Car Company, Prosperous (Laconia)..... *1018
Car Construction, Discussion on, in Kansas City 1055
Car Gates on Northwestern Elevated..... *1180
Car Hoists, Jersey City..... *703
Car-Hour Unit of Comparison: Report on.. 1085
——Used in Camden [Harrington]..... 1056
——Used in Milwaukee..... 821
Car Houses: Drying Motors in Albany..... *146
——Heating, in Montreal..... *24
——Lexington & Boston Railway..... *522
——at Newark, N. J..... *1176
——Steel Rolling Doors for..... *652
——Storing Oil in..... *127
Carnival: at Milwaukee..... *705
——at New Orleans, Floats in..... *347
Cars: Anderson (closed)..... *1193
——Bangor (combination) 264
——Biddeford (closed) *849
——Blue Hill (closed)..... *654
——Brooklyn (closed) *376
——Brooklyn Elevated *1189
——Buffalo (open) *653
——Cape Town (double deck)..... *1007
——Central London *653
——Compressed Air, in New York..... *1019
——Convertible *843
——Double Truck [Heft]..... *1188
——Duplex *654
——Fitchburg (open) *1012
——French Types [Connett]..... *935
——Funeral *702
—— for Mexico *1014
——Geneva, Narrow Gage..... *699
——Havana (closed) *55, *724, *1014
——Home-Made (closed) .....c *240
—— in Atlanta (open)..... *375
——Isle of Thanet (double deck)..... *1012
——Kansas City (closed)..... *482
——Metropolitan Street Railway, New York [Millen] *962
——Mexico (double deck) *478
——New Bedford (closed)..... *481
——New South Wales (combination)..... *162
——Old Point (parlor)..... *263
——Paris (double deck)..... *480
——at Paris Exposition..... *717
——Rochester (closed) *655
——St. Louis (closed) *379
——Spokane (convertible) *566
——Storage Battery, in New York..... 838
——Steel, Proposed for Tunnels..... 280
——Third Avenue, New York (convertible).. *19
——Vincennes (double deck) *627
——Winston (freight) *661
Cars and Car Service in New York [Vreeland] *958
Cars Shipped by Traction Engines..... *1018
Car Specifications 749
Car Step (Mason)..... *1005
Car Wheel Grinder (Springfield)..... *1025
Car Wheels (see Wheels).
Cast-Welded Joint (see Rail-Joint).
Catalogue, Elaborate (M. & E. Co.)..... 1190
Centrifugal Cycle Railway..... *568
Chicago: Advertisements in..... 850
——City Railway, Lighting Track Work at Night 433
—— New Power House of..... 1222
—— Track Tool Wagon of..... *1179
——Electric Traction Company, Storage Batteries Abandoned by..... 391
——Elevated Railway Companies, Annual Reports of 906
——Elevated Railway System, Cost of..... 592
——General Railway Company, Reorganization of..... 850
——Municipal Ownership Regulations in..... 1214
——Northwestern Elevated, Gates Employed on *1180
——South Side Elevated Railroad, Annual Report of 187, 906
——Subway, Plans for..... *766
——Union Traction Company, Advance in Wages 674
—— Election of President..... *583
—— Employees' Clubroom 1213
Chicago & Milwaukee Electric Railway, Operation of Power Plant of..... *605
Chutes for Parks and Pleasure Resorts..... *463
Circuit Breakers: Magnetic Blow-Out (C.-H. M. Co.) *1023
——(Starr) *479

75546

Cincinnati, Lawrenceburg & Aurora, Accident on *731
Cincinnati & South Covington Railway, Prizes for Employees..... 253
Claim Department, Organization of [Uppercu] 124
——(See also Accidents.)
Cleveland Electric Railway, Employees' Clubroom *239
Color Ordinances 782
Columbus, Franchise Discussion in [Sheldon] 1224
——System of *789
Commutator and Bearing Repairs at Council Bluffs 1179
Compressed Air: Cars in New York..*719, *1019, 1214
——Consolidation of Companies.....315, 394
——Motors [Cooke] 891
Coal, Distribution of Energy in Electric Railway Cycle [Herrick]..... *12
Conduits, Electric: on Broadway, New York. *830
——Construction of, in Washington..... c 993
——Development of [Cudworth]..... *1130
——Experimental, in London..... 1114
——(K. A. K.)..... *163
——Operating with Grounds on..... *344
——on Third Avenue, New York..... *75
Coney Island, Spectacular Railway at..... *380
Connecticut: Railroad Commissiners, Report of 58, 1119
——Railway Competition in..... 783
——Syndicate Secures Roads in..... 402
——Taxation in 1206
Connett, A. N..... *748
Connette, E. G..... *303
Consolidations: of Gas, Water and Electric Companies [Uebelacker] 890
——of Small Railways, Economies in..... 447
—— Editorial on 823
——Right to Consolidation Upheld in Georgia 403
——of Street Railways [Holmes]..... 1073
Consulting Engineer, Duties of [Richardson] 26
Controllers: Diagrams *563
——for Shunt Motors [Henry]..... *373
Cooling Table for Condensing..... *606
Cooling Tower, Fanless..... *755
Copper Industry in the United States..... 317
Copper, World's Output in..... 747
Corea, Electric Railway in..... *1151
Corporations, Municipal, Attitude to Public [Boyd] 417
Council Bluffs, Repair-Shop Methods in..... 1179
Couplers: Efficient (Van Dorn)..... *1020
——New Automatic (Auto Appliance Co.).... *1015
Crank-Pin Oiler *1015
Curtain Holder (Quaker City)..... *757

D

Davenport, Ia., Notes from..... *535
Dayton as an Interurban Railway Center.... *325
Demerara Electric Company, Organization of. 1151
Denver: Electric Plans in..... 384
——New Superintendent in..... 1120
——Tax Decision in.....1198, 1206
Derailment, Device to Prevent (Van Dorn).. *847
Detroit: Assessors' Valuations Upheld..... 666
——Rapid Railway, New Equipment of..... *119
——Rochester, Romeo & Lake Orion Railway. *334
Doors for Car Houses..... *652
Double Trolley System: in Havana..... *724
——in Washington *118
Drawbridge of New Jersey & Hudson River Railway & Ferry Company..... *836
Dublin, Controversy Over Cables..... 70
——& Lucan Tramway..... *431
——United Tramways, System of [Shaw]..... *421
Durbin, C. K., Retirement of..... *870

E

Elmira, Municipal Improvement Company, Reorganization of 569, 850
Electricity, Effect of Introduction on Tramways: [von Pirch] 1093
——Discussion on 1154
Electrolysis: in Brooklyn [Sheldon]..... 514
——Deterioration of Peoria Standpipe [Herrick] *1164
——Editorial on 1170
——Investigation in Germany..... 1118
——(See also Return Circuit.)
Elevated Railways: in Berlin..... *980
——Cars for Brooklyn..... *1189
——Electric Equipment for, Editorial on.... 132
——Plans of Manhattan Co., New York....*45, 586
——Proposed Equipment of Berlin Stadtbahn. *152
——Tests of Train Unit Systems in Boston, 395, *440
——Trial Trip of Manhattan Train.....1170, 1194
Employees: as an Element in Economy [Hewitt] 292
——Club, at Camden..... 662
——Club in Chicago..... 1213
—— in Cleveland *239
——Increasing the Efficiency of [Connette].. 874
——Metropolitan Street Railway Association, Entertainment of 1033
——Merit System, as Applied to, Editorial on. 542
——Mutual Benefit Associations in New York 346, 382, 1033
——Rewards for 253
—— in Birmingham 530
—— in Spokane 558
——School for, in Baltimore..... 393
——Suggestions Regarding [Cahoon]..... 812
——Wages Raised in San Francisco..... 289
Energy, Distribution of, in Electric Railway Cycle [Herrick] *12
Engine Builders' Association of the U. S., Annual Meeting of 1207, 1215
Engines: Cut-Offs and Throttling, Editorial on 632
——and Generators for Power Purposes [Ebert] 1217
——Guarantees for High-Speed [Armstrong]. 1216
——4500-hp (Westinghouse) *5
——1500-hp Vertical, Portland, Maine..... *1001
——Requisites for Running Lighting Generators [Reist] 1215
——Two Large, at Paris..... *1113
Englewood, N. J., Hudson River Railway & Ferry Company 268
——Headlights Used by..... *1196
——Important Work of..... *836
——Recent Extension of..... *114
England (see Great Britain and London).
English Electric Manufacturing Company, Organization of 73
Epicycloidal Method for Loading Movable Platform *374
Europe, American Engineers and Tramway Managers in 989
Excursion Business, Possibilities of [Derrah]. 72
Express Service in Pittsburgh..... *1148
Exeter, Hampton & Amesbury Street Railway, System of *232
Exhaust Head (Burt)..... *757

F

Falk Cast Joint (see Rail-Joints).
Falk Company, Works of..... *659
Fans, Electric (Bates)..... *661
Fare Registers (see Registers).
Fares: Argument Against Low, in San Francisco 82
—— [Clayton] 492

VOL. XVI. NEW YORK AND CHICAGO, JULY 7, 1900. No. 27.

SOME NOTES ON THE OPERATION OF THE POWER PLANT OF THE CHICAGO & MILWAUKEE ELECTRIC RAILWAY COMPANY

The satisfactory operation, during the past year, of the power generating and distributing system of the Chicago & Milwaukee Electric Railway, makes some of the unusual features which were adopted in this installation of greater interest to other roads which have difficulties calling for similar apparatus that they have been unwilling to install until it has been tried by pioneers. Among the unusual features of the Chicago & Milwaukee equipment at the time when it was laid out, although they have already

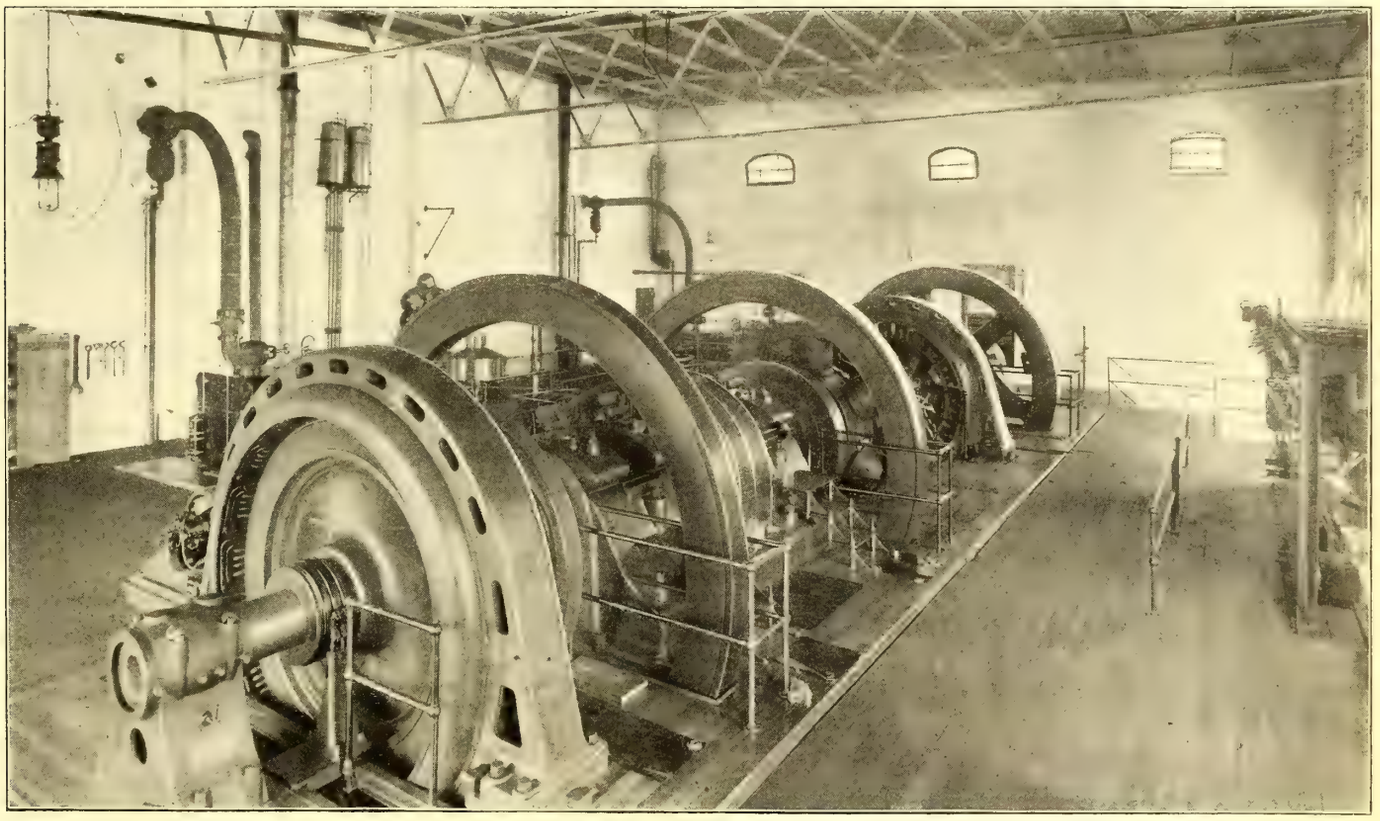

FIG. 1.—INTERIOR OF POWER STATION, CHICAGO AND MILWAUKEE ELECTRIC RAILWAY

come to be more nearly standard practice, are the following: First, a complete polyphase transmission system from the power station to sub-stations with rotary converters and storage batteries; second, the Arnold system of coupling several engines and generators to each other in any desired combination; third, the use of a cooling table for the condensers. The operation of these three features will be explained below in the reverse order to that in which they are here mentioned, the cooling table being taken up first.

There are in the power station at Highwood two Filer & Stowell tandem-compound horizontal engines of two sizes, in order to give at all times a load factor as high as possible with such a small number of engines. The exhaust steam from these engines is handled in two Deane jet condensers and independent air pumps. The station being inland, there is no opportunity for obtaining sufficient cold water for condensing purposes. A cooling pond of sufficient area to handle the exhaust steam output of this station would prove expensive in this location, and cooling towers would require a considerable amount of power for the operation of their blowers, if of the forced-draft type, and would be quite expensive if of the natural-draft type. On this account the consulting engineer, B. J. Arnold, decided to use a cooling table, this being virtually a small cooling pond, the surface of which is multiplied by causing the water to circulate over a number of wooden platforms, slightly inclined so as to cause a flow of the water from end to end of each. The arrangement of these parts is clearly indicated in the view of one end of the cooling table, Fig. 2, and the detail drawings shown in Fig. 3. In this case the number of platforms over which the water has to flow before it falls into the pond is three; the platforms being so inclined that the water flows back and forth over the whole surface of all of them in succession before falling into the pond, from which it is drawn by the condenser suction. The air is allowed to circulate freely between the

platforms, which are exposed so that the wind blows through and constantly carries off from them the water which evaporates. In this way the available surface for evaporation over a pond occupying a given space is greatly increased, making it possible to cool the condensing water of a large plant in a reasonable space without power-consuming auxiliaries or such expensive draft-producing towers as are necessary in a natural draft arrangement.

At the Highwood plant the pond itself is about 150 ft. x 60 ft. in size, banked or excavated to a depth of about 5 ft., a 13-in. brick wall being carried up from the banks to a height of about 2 ft., giving a basin about 7 ft. deep. This is floored by 4 ins. of stone concrete, the walls of the basin having sloping faces of stone concrete with a ⅜-in. cement

anticipated. With the usual load on the plant, which drives twenty motor cars, most of them long heavy interurban cars, and eighteen trailers, a vacuum of about 22 ins. is obtained in the summer, this running up to 24 or 26 ins. in the winter season. In ordinary weather the condenser discharge has a temperature of 115 or 120 degs., the water being returned at about 90 degs. F. The cylinder oil from the engines collects, as the illustration shows, in the corners of the pond, and can be drawn off and partially recovered, if desired. The evaporation from the pond is, of course, supplied by the addition of fresh feed water obtained from the town water supply, this feed water finding its way to the cooling pond through the jet condensers.

As noted above, the engines and generators are all set

FIG. 2.—COOLING TABLE AND POND

facing, as is clearly shown in the drawings. The table itself is not as large as the pond, being only 132 ft. in length by 31 ft. in width, the arrangement of its timbers and planking being clearly shown in the drawing. The outcoming hot water from the condensers discharges on a flaring incline, as shown in the photographic illustration, Fig. 2, being distributed the full width of the table by distribution boards, forming a sort of slotted dam. The table, of course, steams constantly when the plant is in operation, as the view indicates, but the steam is not found objectionable in any way either around the property of the railroad company at Highwood or the neighboring residence district, and is dissipated in the coldest weather without the formation of any ice on neighboring objects as might be

up with their shafts in one line and are provided with magnetic clutches for driving any desired one or more of the generators from either or both engines; this being probably the first railway plant in this country completely equipped with this system and its magnetic clutches, by means of which machines may be coupled or uncoupled while the apparatus is in motion. The general arrangement of the engines and generators is shown in the power house plan, Fig. 4. There are three generators, one a 250-kw direct-current machine designed to supply that part of the line which can be reached economically with direct current from the power house. The other two machines are 25-cycle three-phase alternators, each rated at the same power as the direct-current machine, or 250 kw. As will

be seen by the plan, and by the general view, Fig. 1, one of the alternators is mounted outside the larger engine, the other alternator and the direct-current machine being mounted between the larger engine, which is of the center-crank type, and the smaller engine, which is of the side-crank type and is located at one end of the line. The alternator located outside of the large engine can be driven from that engine alone, but either or both of the machines between the two engines can be driven from either or both of the engines, working either independently or coupled together. The arrangement of the shafts and couplings for accomplishing this purpose is shown more clearly in the section of that part of the shafting between the two engines, reproduced in Fig. 6. In this drawing it will be seen that the rotating parts of the two generators are mounted, not on the solid shaft itself, but on hollow shafts

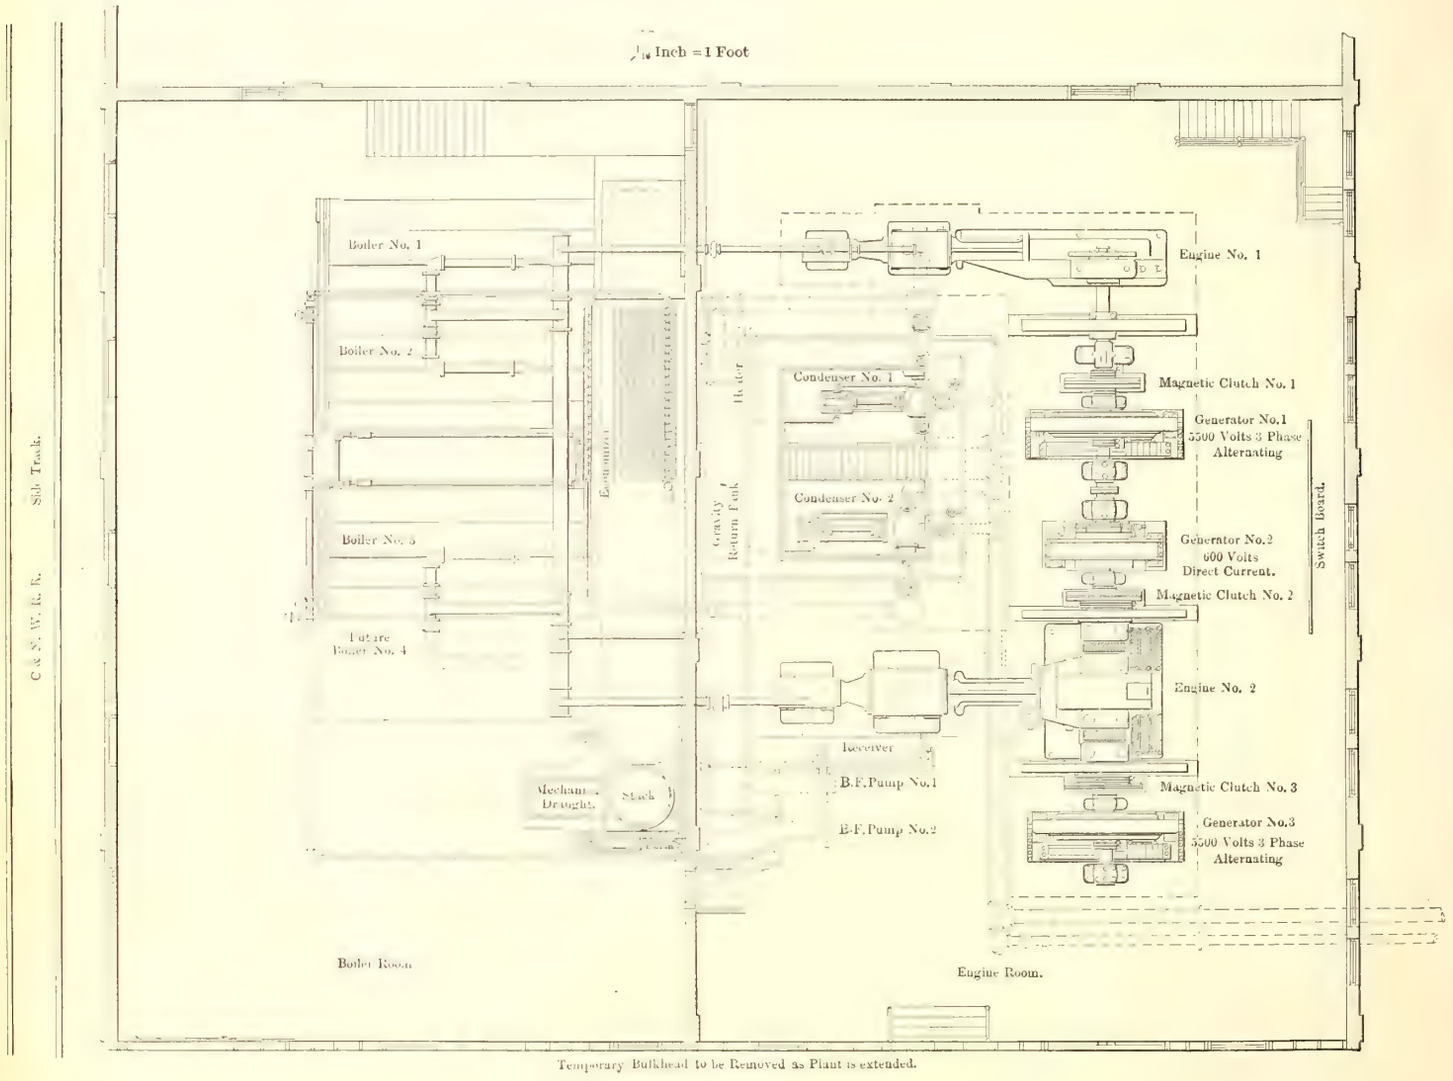

FIG. 4.—PLAN OF POWER STATION

together and thus join the dynamo quill to the engine shaft. By energizing two coils in one magnetic clutch the solid shaft, the quill and the engine shaft may be all clutched together if necessary. Thus, for example, by drawing together the two outer rims of the right-hand clutch, as shown in Fig. 6, the direct-current generator is connected to the large engine; by drawing over the central rim of the same clutch and by attaching the central rim of the left-hand clutch to the right-hand rim of the same clutch both generators are connected to the large engine. In a similar way either or both generators can be connected to the small engine, or one generator can be connected to each engine or both engines can be clutched together, driving either or both generators.

It will be noted that the central solid shaft is in two sections, fastened together at the center by an ordinary bolted flanged coupling, for convenience in erecting and repairing. This solid shaft runs in two shaft bearings immediately adjacent to the central coupling. When its ends are not clutched to the quill or engine shafts the greater part of the solid shaft overhangs its bearing. When its ends are not clutched in the magnetic clutches, however, the solid shaft is not rotating, so that the overhang is no disadvantage.

or quills surrounding the solid shaft. Each of these quills —one carrying the armature of the direct-current machine and the other the rotating field of the alternating-current machine—is supported in two quill bearings and carries on one end a disc of what is termed a "three-way magnetic clutch." Each of these three-way magnetic clutches has three sets of spokes and three rims; the central one is attached to the inner solid shaft, one of the outer rims is attached to the adjacent quill and the other to the adjacent engine shaft. Coils embedded in the rims and concentric with the shaft are arranged to draw the central rim toward either of the outer rims and thus clutch the solid shaft to either the quill or the engine shaft. Other coils are provided to draw the two outer rims of one magnetic clutch

The alternator at the extreme end of the system and outside of the larger engine is also connected to this engine through a magnetic clutch, but can be driven only by the large engine. It will be noted from the general view, Fig. 1, that this alternator is also mounted on a hollow quill,

so that when extensions are made to the system a solid shaft can be put through this alternator to connect it to the next engine in the line in the same way that the two other generators can now be connected to either engine.

By means of this system the failure of any one dynamo does not incapacitate either engine, nor does trouble with any engine throw out of service any dynamo, while failure of the larger engine only shuts down one alternator. The larger engine is sufficient in size to carry the usual load, and a reserve source of power is provided without using another engine of the same size by fitting the smaller engine with a by-pass in such a way that both its cylinders can be supplied from the boiler and exhausted into the condenser, a reducing valve being used in the connection to the low-pressure cylinder. In this way it will deliver enough power to run one alternator and the direct-current machine to carry the usual load on the power plant. There being only one direct-current generator, this is always kept in operation to feed the adjacent sections of track, although service could be continued in case of failure of this generator by feeding back from the sub-stations and by virtue of the storage battery at the power station. Normally the direct-current machine and one alternator are run by one engine, in case of light load by the small engine, and in case of heavy load by the large engine. At the time the photograph reproduced in Fig. 1 was taken, it will be seen that the large engine was in operation, driving the alternator at the left-hand end of the line and the direct-current machine. At any time the couplings may be changed so that the small engine at the right-hand end of the line may drive the alternator adjacent to it and the direct-current machine. There is no provision for bringing the generators up to speed by electrical means when the engines are running so that the generators can be started and coupled to the engines without stopping the latter, an arrangement which is in some cases provided with the Arnold system in lighting stations. If the load is sufficiently heavy to call for the operation of both the alternators at

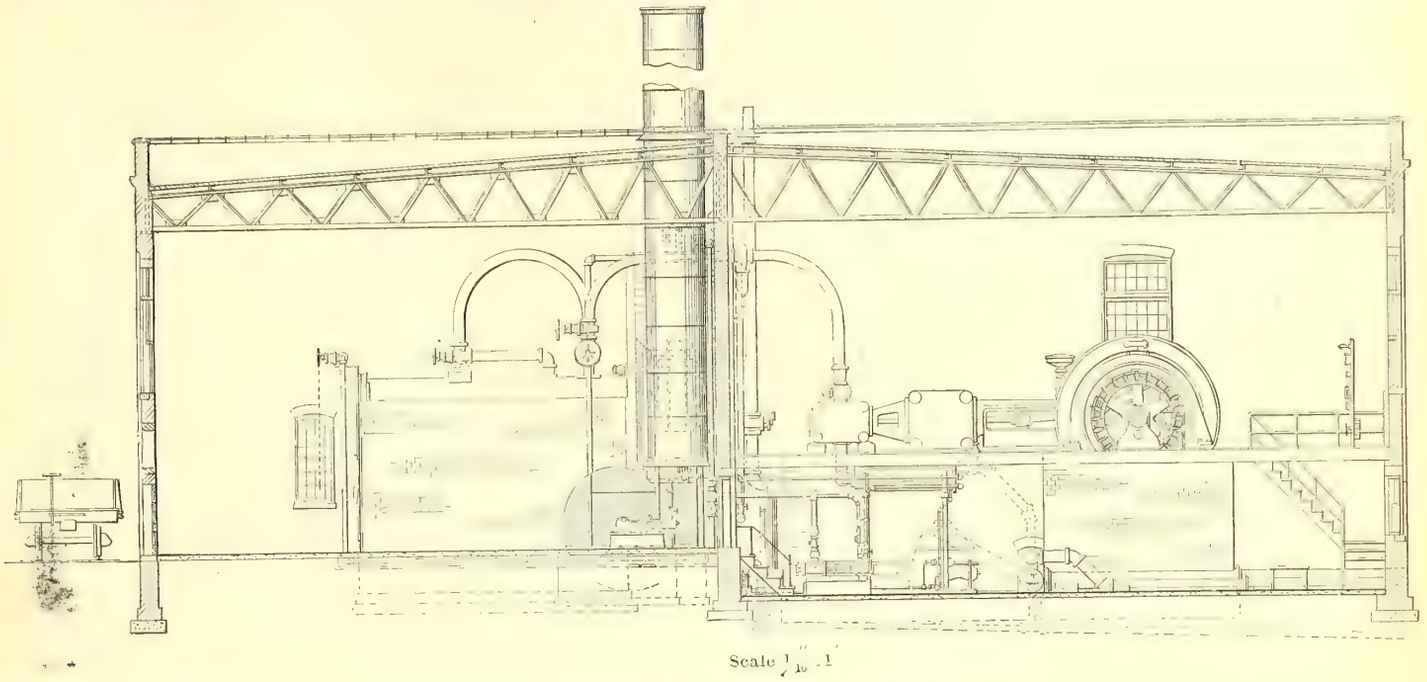

FIG. 5.—SECTION OF POWER STATION

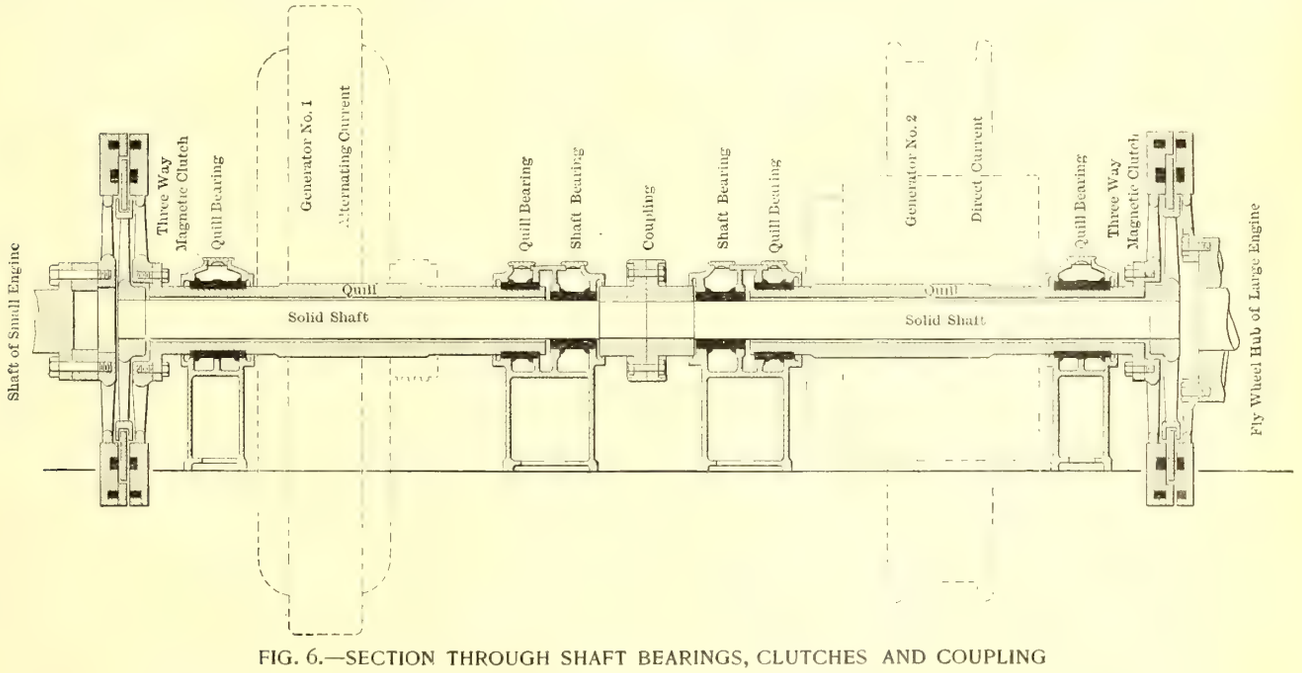

FIG. 6.—SECTION THROUGH SHAFT BEARINGS, CLUTCHES AND COUPLING

the same time they are generally driven from the two engines respectively, one alternator taking the load of one sub-station and the other taking the load of the other sub-station, so that they are not in parallel with each other. They can, however, be synchronized in the usual way and thrown in parallel, after which the clutches may be operated if desirable, so as to couple them mechanically to each other and drive them from the large or both engines. The fields of the alternators are supplied by exciters which are belted on the face of the magnetic clutches, as shown in Fig. 12, the belt covering only a portion of the surface so that it will not interfere with the operation of the parts.

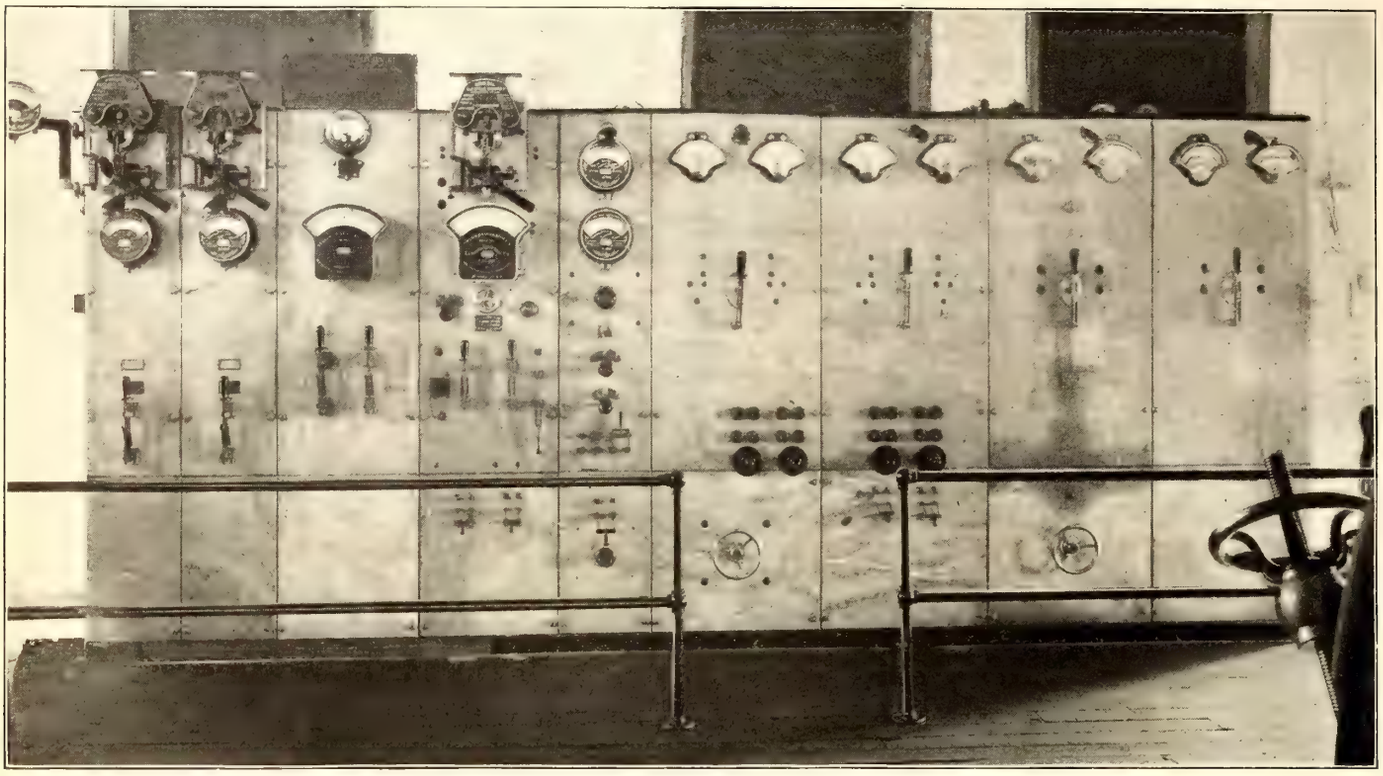

FIG. 8.—SWITCHBOARD AT MAIN STATION

FIG. 7.—CAR ON TRESTLE

THE ELECTRICAL CIRCUITS

The alternators deliver their output at full line pressure of 5500 volts, thus avoiding the necessity of any step-up transformers. There are no fuses in the circuits between the generators and the switchboard, spring-expulsion type fuses being used in the outgoing high-tension lines. The switchboard of the generating station, as shown in Fig. 8, is somewhat unusual on account of the combination of direct and alternating-current machinery. To the left are two ordinary direct-current feeder panels, next to which is a battery panel, and next to that a generator panel; the narrow panel is for the exciters, the remaining four panels being alternator and alternating-current line panels. The only notable feature about this board is the use of high-tension voltmeter receptacles and plugs, by means of which only one transformer per voltmeter is used instead of a transformer in each phase of each line to be measured, as is required when low-tension plugs and receptacles are made use of.

The overhead trolley line, 27

miles in length, is divided by section insulators into three sections, each about 9 miles in length. The middle section is supplied from the direct-current generator at the power station and each of the two end sections is supplied from a rotary-converter and storage-battery sub-station. The three sections are normally tied together electrically on the 600-volt lines so that they help each other. The two sub-stations are almost exactly like each other and each contains two 125-kw General Electric rotaries, a view of a pair of these machines being shown in Fig. 9, from which it will be seen that they are of the type with overhanging collector rings. They were set up with their shafts in line in order that they might be coupled together to allow for the turning of the commutators and to prevent pumping. Although the sub-stations are fitted with storage batteries, this available source of current for starting the rotaries as direct-current motors is not used, the machines being started from the alternating-current end. No reactive coils or compensators are provided, the alternating-current leads of the machines being simply closed, with the fields of the rotaries unexcited, the machines coming up to speed by an internal induction-motor action, this method requiring less skill on the part of the operators than starting from the direct current end. It would be preferable, in a plant of this kind, provided the operatives were sufficiently skilled, to start from the direct-current end, either by means of power transmitted from the generator at 600 volts, the 600-volt wires being normally connected together, or better by means of current from the storage batteries, and it was the intention of the designer of the system to operate them so by batteries ultimately, the only objection being the increased complication.

The rotaries are compound-wound and provided with

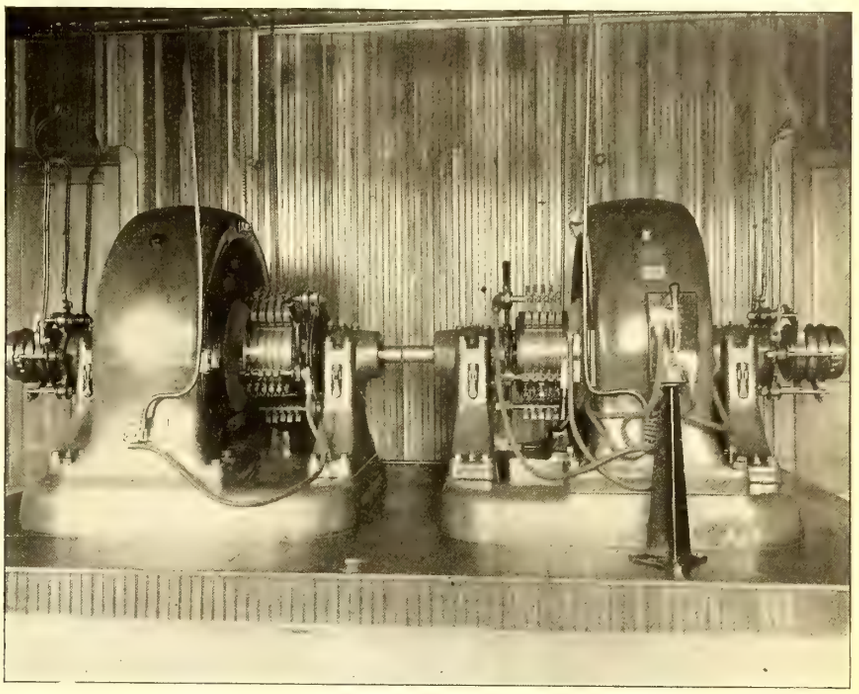

FIG. 9.—ROTARIES AT SUB-STATION

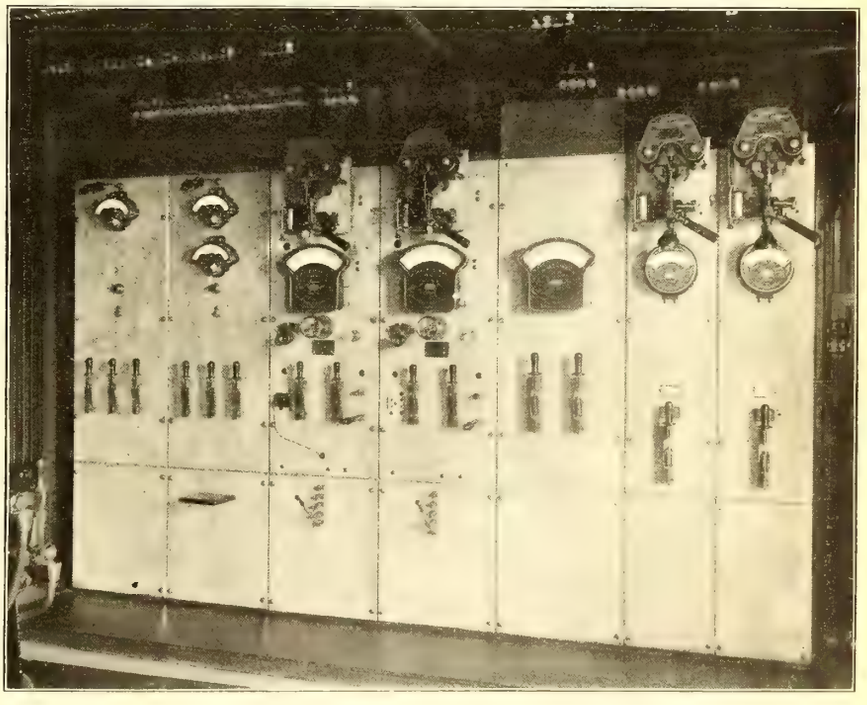

FIG. 10.—SWITCHBOARD AT SUB-STATION

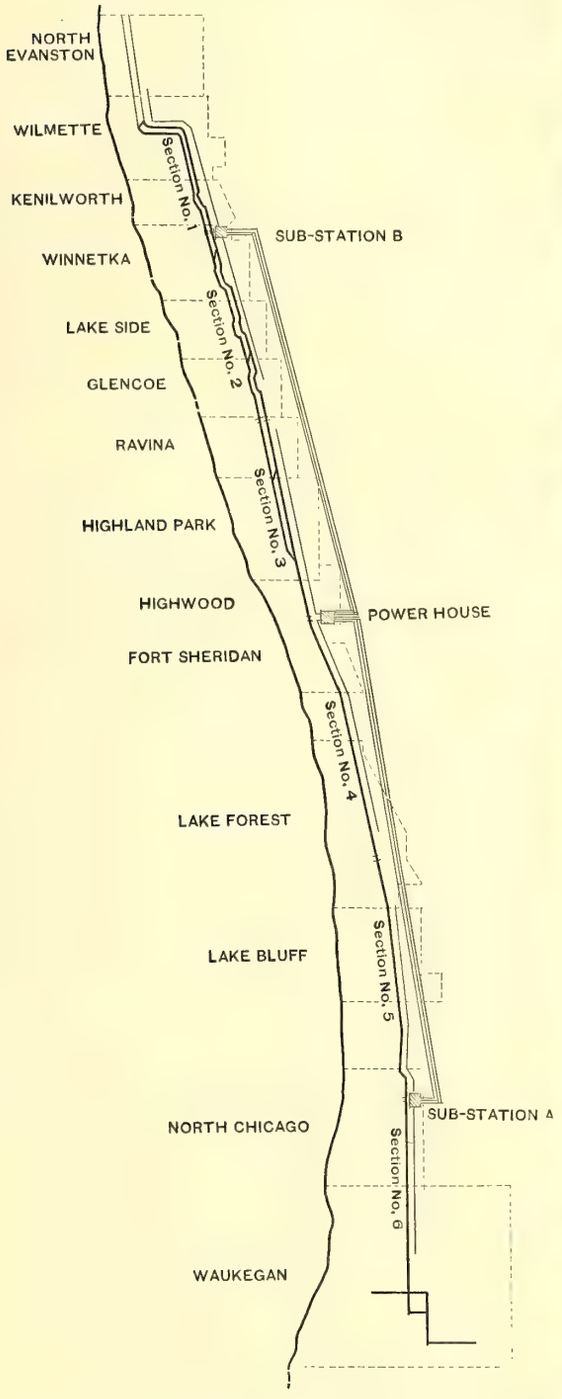

FIG. 11.—MAP SHOWING LOCATION OF FEEDERS

the usual equalizer, the series coils tending to keep up the voltage even without the use of special reactances in the alternating circuits, the reaction of the machine windings of the transformers and of the line being sufficient to give practically constant potential under load variations. There

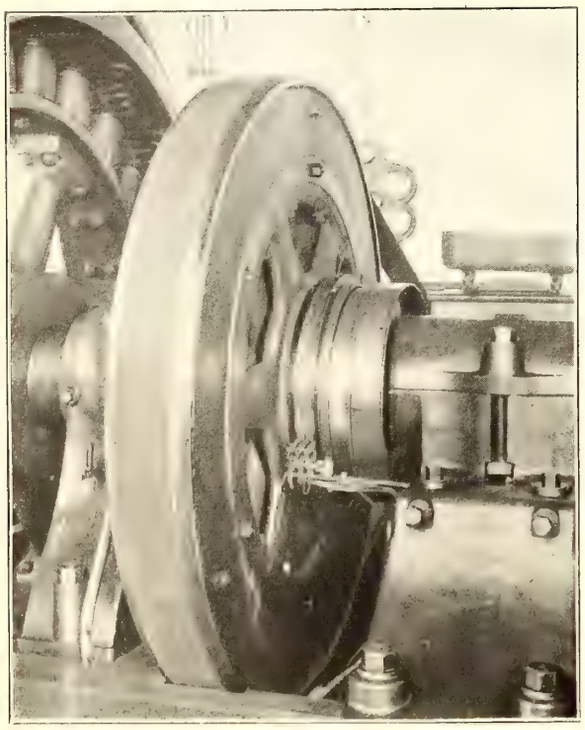

FIG. 12.—ONE OF THE MAGNETIC CLUTCHES, SHOWING COLLECTOR RINGS AND BRUSHES

are no circuit breakers in series with the batteries. No serious trouble is experienced with hunting of the rotary converters, even though the generators are driven by single-crank engines.

As noted above, the road, which runs on private rights of way for about three-fourths of its 27 miles, through many suburban towns scattered along the shore of Lake Michigan from Evanston to Waukegan, is equipped with some twenty motor cars and eighteen open trailers. The large double-truck through cars are equipped with G. E. 57 motors, geared up for a speed of about 30 miles per hour, which can readily be made on the long stretches of well ballasted private rights of way which exist between some of the towns passed through. The fares charged run about 1 cent per mile, varying from 5 to 35 cents, and the traffic developed during the short season the road has been in operation amounts to 7000 or 8000 passengers per day in the winter, and 30,000 to 35,000 in the summer, with more on Sundays and holidays.

The successful operation of this road with its several deviations from standard practice reflects credit on the gen-

Polyphase Apparatus for Long-Distance Roads in Providence

The Providence & Suburban Railway Company, of Providence, R. I., operates several long-distance extensions in close connection with the city lines of the Union Railroad Company, of Providence. These companies are about to install an extensive three-phase system for supplying power from the Providence station to sub-stations on the extensions. Two 1500-kw three-phase 25-cycle General Electric machines will be erected as generators for this purpose. George B. Francis, formerly in charge of the engineering work on the Southern Terminal Railroad station in Boston, has charge of this work in Providence.

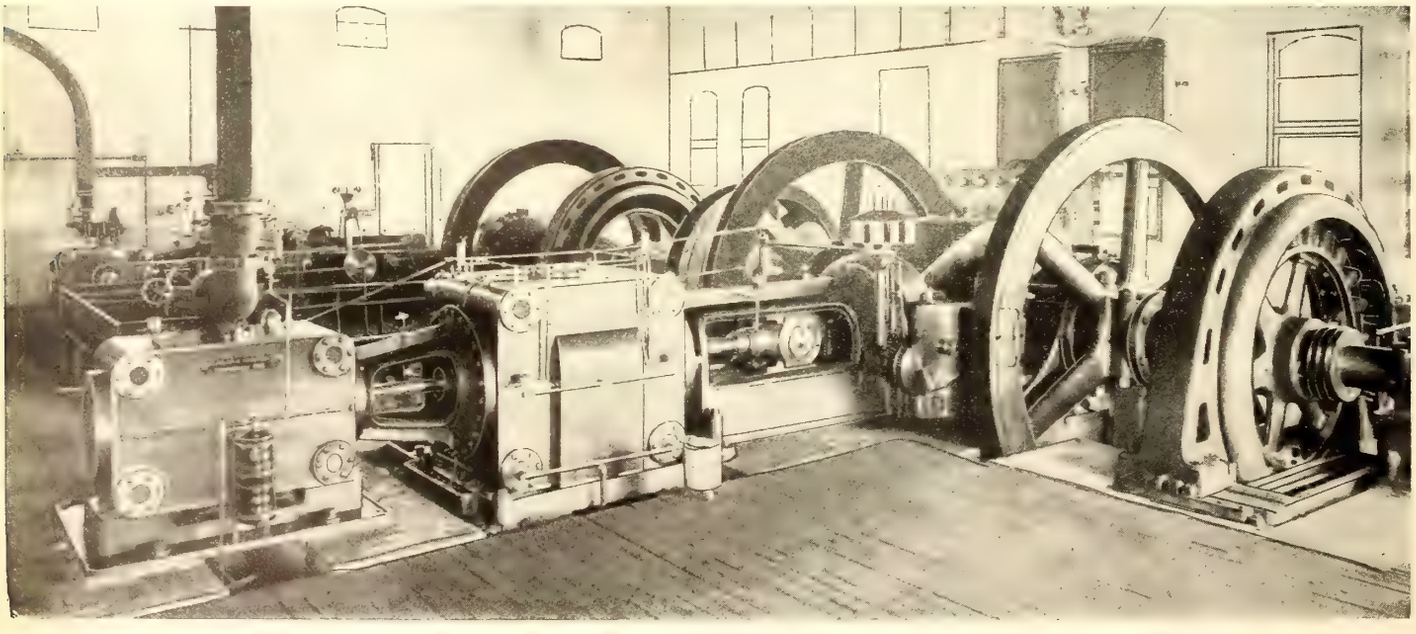

FIG. 14.—VIEW OF ENGINES IN POWER STATION

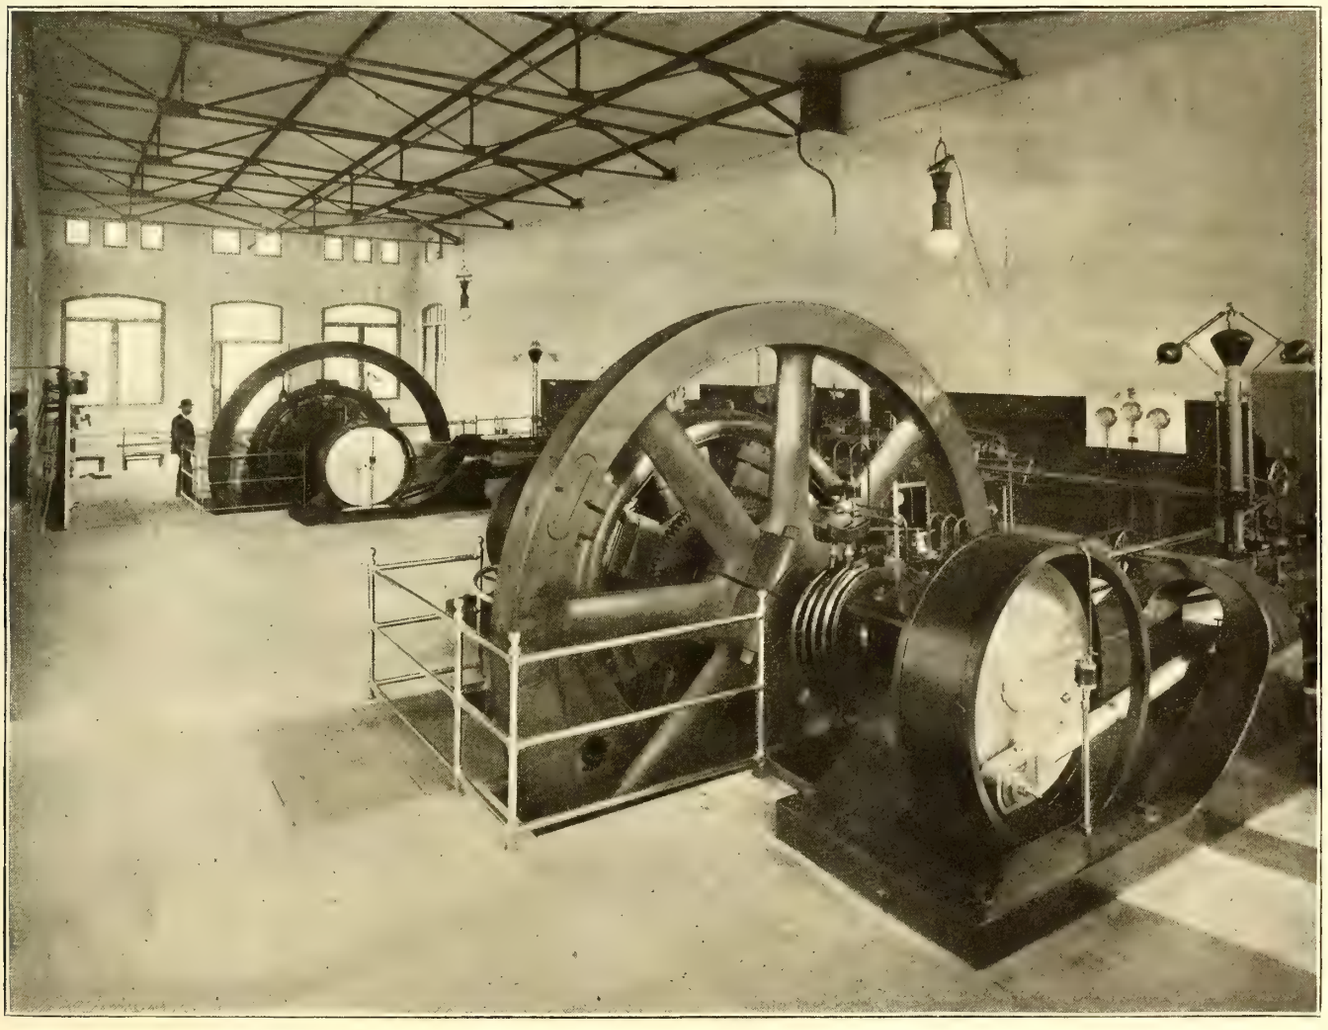
The Worcester & Webster Electric Railway

The City of Worcester, Mass., the second city in the State in wealth and population, compares very favorably with, if it does not exceed, Boston in the variety and extent of its industrial enterprises and is growing rapidly. For a long time the city displayed unusual conservatism in the introduction of suburban electric railway lines. But being the center of a highly industrial region, this condition could not long remain, and to-day Worcester is abreast of all rivals in local and suburban facilities for rapid transit.

Of the six distinct suburban lines now in operation, which practically annex to Worcester the principal towns and villages within a radius of 20 miles, and with various terminal connections beyond, the Worcester & Suburban Railway Company's lines to Spencer and Millbury were the first to be completed, and the Worcester & Webster Street Railway is the latest. This latter line, which has received much favorable comment for all that relates to thoroughness in construction, high speed and convenience, not to say luxury, of the traveling public, is the subject of this article.



INTERIOR OF ENGINE ROOM, WORCESTER & WEBSTER ELECTRIC RAILWAY

The route runs through one of the most beautiful and picturesque sections of Central Massachusetts, passing southward through the old time settlements of Auburn, North Oxford and Oxford, the latter a typical New England town of homes and churches, with many historical associations, including the remains of the old fort of early Colonial days on Huguenot Hill. Continuing through East Webster, a delightfully rural region, to the busy town of Webster with its population of 12,000, the pleasure seeker by this route arrives within a short distance of one of the largest fresh water lakes in the State, enjoying the euphonious Indian name of "Chaubunagungamaug."

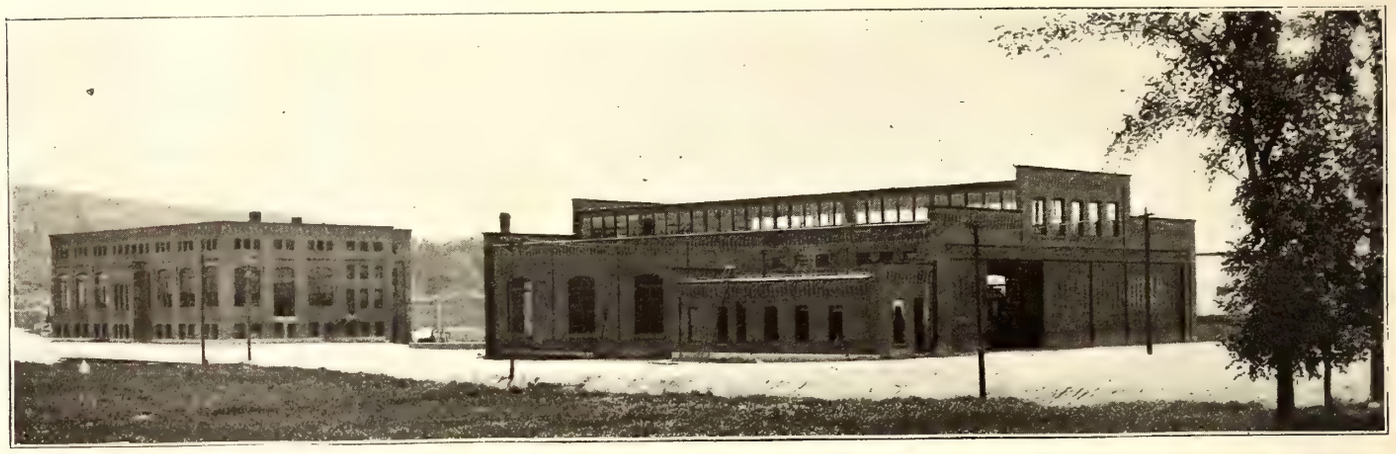
The company was organized with a capital stock of $150,000, rights of the various towns obtained, and $150,000 worth of bonds have been issued. The engineering of the whole enterprise was conducted by E. E. Carpenter, president and manager of the New England Electric Railway Construction Company, of Worcester, Mass. The work of construction was begun in the spring of 1899 and the cars were in operation in the following September, in spite of many obstacles of grade and alignment.

This task included the building of $3\frac{1}{2}$ miles of new streets in the towns of Auburn and Oxford, with roadbed of gravel, bridges of steel I-beams, with 60-lb. steel rails, 60 ft. long, on 7-ft. chestnut ties, and equipped with 00 copper trolley wire, 500,000 circ. mil, rubber covered and 0000 copper feed wire, with turnouts about 350 ft. long and automatic switches. The ties are chestnut, 5 ins. thick x6ins.face, and are spaced 2 ft. centers. The joint plates are the standard four-bolt, 24-in. angle bar. The bonds are all No. 0000, about one-half being of the Protected type, the others being Crown bonds. The poles throughout are of chestnut, 30 ft. long and 10 ins. in diameter, 5 ft. from the butt, except in the village of Oxford, where octagonal hard pine poles 30 ft. long are used. The overhead material is of the West End type, with General Electric switches and flexible brackets.

The company has a fine location in the town of Oxford

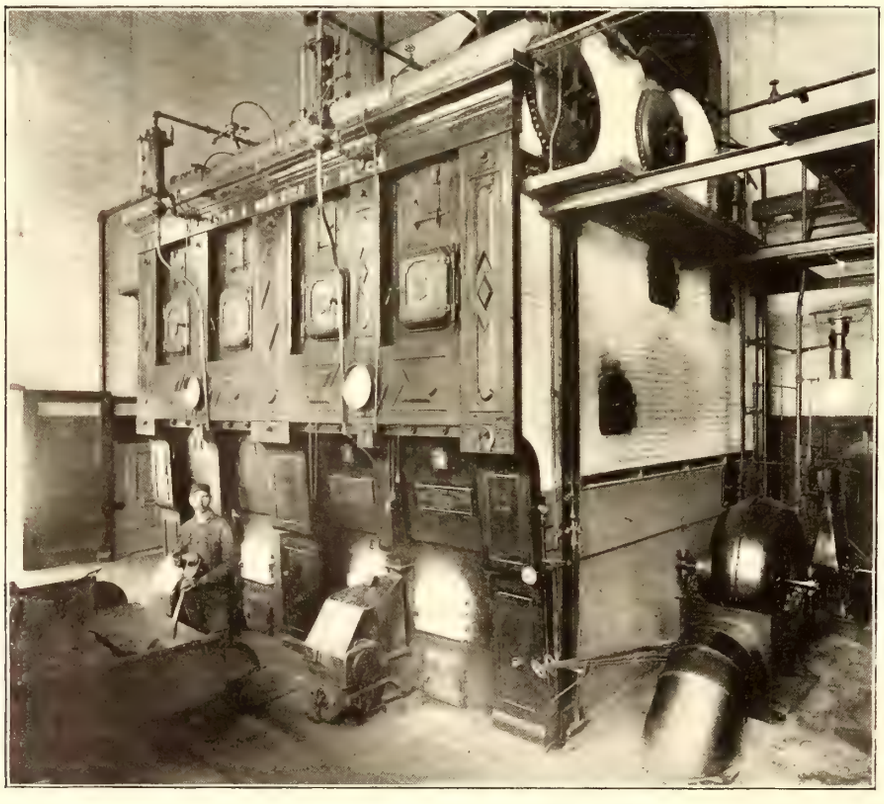
for the power station and car house, on a lot of land situated between the main street and the N. Y., N. H. & H. R. R., consisting of about 3 acres, with a frontage of railroad of about 100 ft.

The power station is of brick with granite and brownstone trimmings, as shown in the engraving. The engine room floor is of steel with brick arches and granolithic top.



POWER STATION AND CAR HOUSE

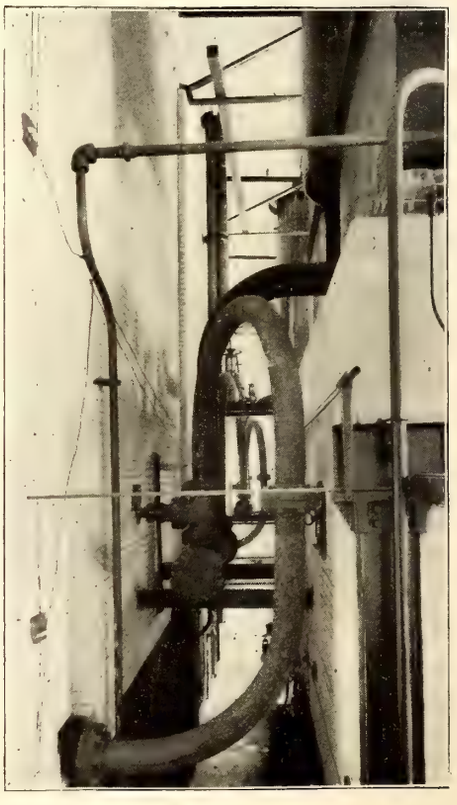
The boiler room floor and the floor under the engine room is of 4-in. Portland cement concrete, and is absolutely fireproof. Owing to this construction it will not be necessary to carry any fire insurance on buildings or equipment. The power equipment is about 1000 hp, with buildings large enough to double the capacity when needed in the future.



BOILERS AND UNDERFEED STOKER

The boilers are of the Stirling water-tube pattern, fitted with the American under-feed stoker, which has proved very satisfactory on other New England roads. The company also uses mechanical draft, having installed a No. 9 Sturtevant blower directly connected to a small steam engine. By this means no large stack is needed and the draft is automatically regulated by a very unique arrangement, consisting of a Spencer damper regulator attached to the blower engine steam valve.

The pump room is a separate compartment 12 ft. 6 ins. x 18 ft., equipped with one large duplex Blake pump for use in filling the feed-water heater, and the entire water system for both the power station and car house is arranged to work automatically and to maintain a pressure of from 100 to 150 lbs. For emergency use, one smaller and two larger pumps are used, each of the latter being capable of feeding the large boilers from the Cochran heater, which heats the water from 210 to 212 degs., by economizing the exhaust steam from the pumps and condensers.



HEADERS AND MAIN

The steam piping is of bent pipe, all put in by the Carman, Thompson Company, of Portland, Maine, and there are three distinct ways of feeding the water to the boilers, so in case one should become defective there are two other ways of supplying water.

The engine room is complete in every particular, fur-

nished with two direct-connected, cross-compound Hamilton-Corliss engines of 600 hp each, of 120 r. p. m., and two 275 kw direct-connected Westinghouse generators on foundations 12 ft. high, built of brick all laid and puddled with Portland cement on 18 ins. of crushed stone and Portland cement concrete. The entire building is fitted with hot and cold water and open plumbing. The gravity oiling system is used, the oil running on the bearings all the time and then passing through a pipe to the filter, where it is filtered, pumped to tank and used over again.

The coal pocket, of the steam railroad trestle pattern, is large enough to hold 25,000 tons of coal. The coal descends through chutes to hand cars which run on a track passing through the boiler room in front of the boilers. The boiler room is also connected with the main line of track for the removal of cinders and ashes to the roadbed by the construction car at one operation.

The car house, which adjoins the power station, is of brick with brownstone trimmings well arranged and ample

INTERIOR OF CLOSED CAR

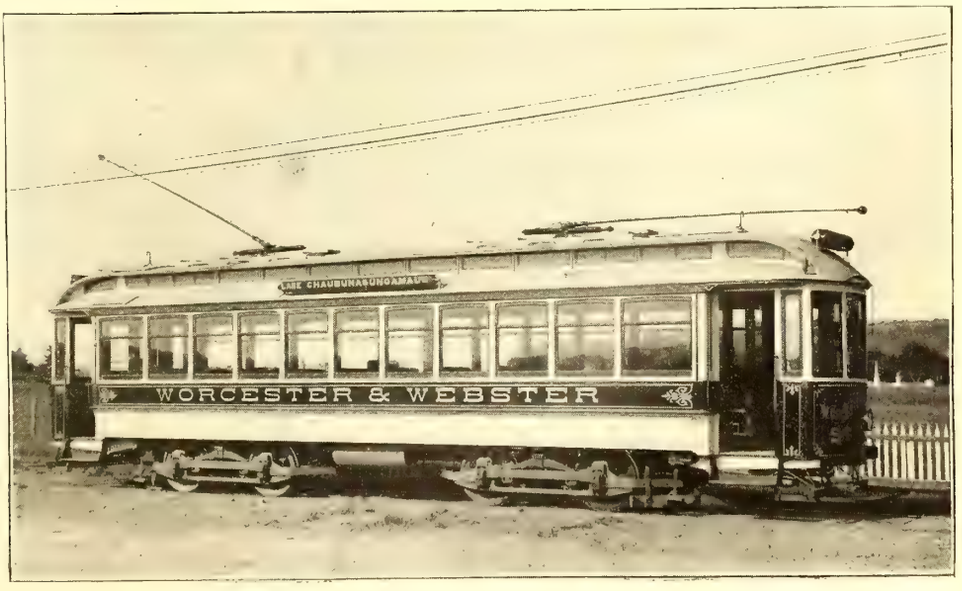
INTERIOR OF CAR HOUSE

for the purpose, having seven tracks and a "Y," including front sliding doors hung at the top, and the trolley wire is arranged to extend whole into the house without cutting. The office, conductors' and motormens' headquarters are furnished with all necessary appointments. The plans for the station and car house were drawn by J. William Patston, architect, of Worcester, Mass.

The company has reason for great pride in its rolling stock, which consists of seven handsome box or closed cars, about 43 ft. long. They are finished in quartered oak inside, with plush cross seats, and each has a capacity of from forty to forty-four people. There are eight fifteen-bench and two twelve-bench open cars. The cars, which are illustrated herewith, were built by the Laconia Car Company Works, of Laconia, N. H. All the cars are mounted on Laconia double trucks, with the motors suspended outside the axles. International registers are used.

Each car is equipped with two 50-hp Westinghouse high-speed motors and Standard Air Brake Company's axle-driven air compressor brakes and chime whistles, and the new Carpenter sand box, the invention of E. E. Carpenter, of the New England Electric Railroad Construction Company.

In addition to the electric push-button signal for stopping, each car carries a telephone, which allows the making of connections to the car house from any point on the line. This is accomplished by using a telephone wire running the entire length of the line, and di-



STANDARD CLOSED CAR

rectly connected with the car by a bamboo pole properly wired. The cars are not dispatched by telephone, but in case a car is delayed and obliged to wait at a turnout, the conductor can call up the main office and receive orders as to whether to wait or go ahead, thereby avoiding any liability of accident by trying to steal switches.

The road is also furnished with a large construction car equipped with motors and all electrical appliances for repair work or in case of accident; also two Taunton snow plows.

A parlor car is now building from special designs which is to be one of the finest of its kind ever built. It is 45 ft. long, with parlor, smoking room and toilet compartments with buffet and refrigerator appointments. The finish is mahogany with artistic carvings, bevel plate glass and art glass, mirrors and windows, and has a seating capacity of twenty-four luxurious parlor chairs, both cane and upholstery. These, with electric push-buttons, call bells and telephone system, make this palatial car one of the finest of its kind in the country.

Although the line has been in operation but a few months, it already has a large through and local patronage and is destined to be the popular route for quiet pleasure seekers as the season advances. As stated, the total cost of construction and equipment of this line, which is about 17 miles long with turnouts, was about $400,000. Of this amount the roadbed and track cost about $110,000; the special work, grading, switches, frogs, new streets, fenc-

VIEWS ON LAKE CHAUBUNAGUNGAMAUG

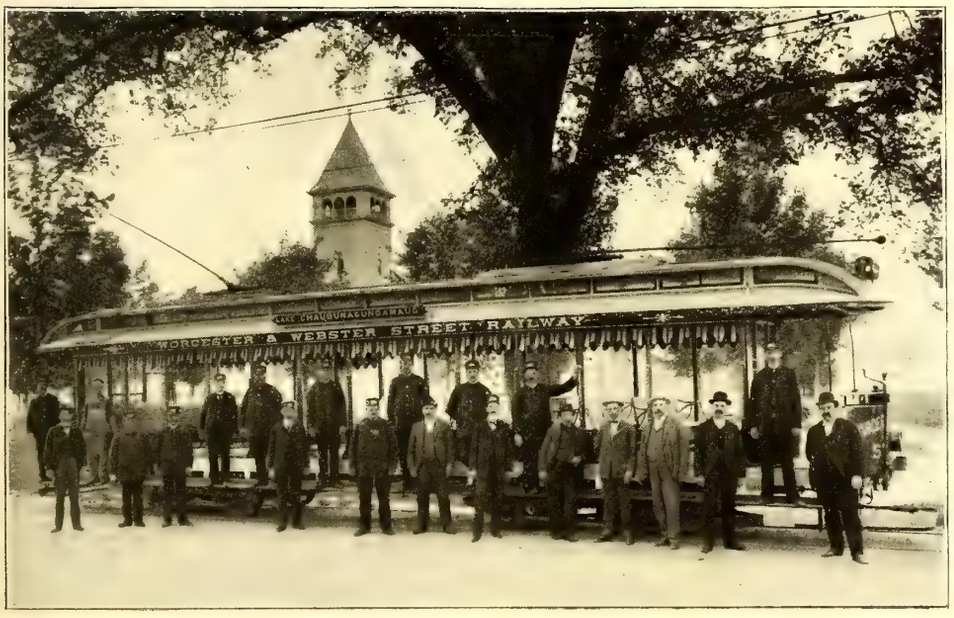
ing, etc., about $60,000; the overhead materials, including poles, brackets, feed-wire, trolley wire, etc., about $48,000; the rolling stock, about $47,000; the car house, complete, about $22,000; the power station, about $30,000; the land, well, grading, etc., about $8,000; the power station equipment, about $70,000; the miscellaneous items, such as office furniture, telephone system, tower wagon, etc., amounted to about $5,000.

The officers of the company are Julius Garst, president; Fred Thayer, vice-president; W. A. Bailey, treasurer; E. L. Parker, auditor. The construction, as stated, was performed in its entirety by the New England Electric Railroad Construction Company, of Worcester, Mass., of which Mr. Carpenter is head, and H. F. Leland the clerk and treasurer. With Mr. Carpenter were associated Charles A. Midddlemas and H. F. Lincoln, the constructing engineer of the New England Electric Railroad Construction Company. These gentlemen have received many compliments upon the very successful manner in which this road has been equipped.

CAR HOUSE

Testing Public Opinion in Chicago.

The agitation over changing the motive power on the lines of the Union Traction Company, of Chicago, led to a novel test of public sentiment June 19. Baskets were put on the cars and each basket had beside it an invitation for each passenger to place in it a ballot expressing his opinion upon the present system of transit. The inquiry was made by the North Side Business Men's Association. The result was that 3802 voted in favor of the overhead trolley, and only a few cast ballots for other methods of transportation. This is a pretty good indication of the satisfaction given by the trolley system, as compared with the other methods employed in that city



VIEW OF CAR AND OPERATING FORCE

German Managers to Make a Trip of Inspection to America

Under the auspices of the Verein Deutscher Strassenbahn und Kleinbahn Verwaltungen, which is an association comprising the principal street railway companies of Germany, an extensive trip of inspection will be made by a number of members of that association to the United States next year. The object of the trip is to study the latest developments of electric traction, both surface and elevated, in the different cities. From twenty to twenty-five gentlemen have already signified their intention of joining the party, and it is thought that the advantages of the trip, as showing the latest developments of American practice in electric railroading, will appeal so strongly to other members of the association that before the date of starting the party will comprise representatives from practically all of the larger cities of Germany, as well as of some of the larger manufacturing companies. The party will leave Germany during the early part of May, 1901, by either the Hamburg-American or North German Lloyd line, and New York will be the first city visited. Other cities which the party is planning to visit are Boston, Cleveland, Chicago, St. Louis, Cincinnati, Washington and Philadelphia. The entire trip will occupy from six to seven weeks, of which from fifteen to seventeen days will be occupied by the ocean voyage. The party will spend one day at Niagara Falls on the trip between Boston anod Chicago. The cost of the trip, including the steamship travel, railroad fares, etc., is estimated at about M3,000 per person. This is considered an outside figure, and should include all expenses. Heinrich Vellguth, secretary of the association, has the details of the trip in charge.

Form of Train for Reducing Air Resistance

Although somewhat outside of electric railroading the experiments now being carried on by Frederic U. Adams on the Baltimore & Ohio Railroad, in an effort to reduce air resistance, will be of some interest to workers in high speed electric railroading, whether the results prove successful or not. A great many attempts have been made to reduce this part of a train's resistance, a factor which, at high speeds, is undoubtedly a very important one. The subject was quite thoroughly discussed in a series of articles in the STREET RAILWAY JOURNAL about a year ago, in which one writer, Henry Graftio, formerly chief engineer of the Heilmann Company, of France, stated that he believed that a form of train in which the spaces between the cars were closed, and the front and rear of the train were provided with shields, shaped somewhat like the bow and stern of a boat, would appreciably reduce the air resistance of the train. The closing of the spaces and the shape of the rear car were considered more important than the pointed shape of the front end of the train. This opinion coincides with the views held by Mr. Adams, who has been working on the subject for the last ten years.

FRONT END OF TRAIN

REAR END OF TRAIN

In the tests made with the train shown it is claimed that a considerable reduction in train resistance has been secured, and a gain of from 7 to 10 miles an hour was made with the same engine over the same tracks, drawing the test train, and also a standard train with the same number of coaches. No very accurate measurements of power, however, have as yet been obtained, so that it is impossible at the present time to predict what the saving will be, if it is practically anything. It is understood that a special dynamometer car and tender are in process of construction, and when experiments are made with this apparatus greater knowledge can be had as to the practical value of the device. It seems to be generally admitted that the pulling back action of the last car is one of the principal factors in train resistance. It would be interesting to place the dynamometer car both ahead of the cars and in another test just ahead of the rear car, and thus determine whether the shape of the rear car on Mr. Adams' train actually lessens the train resistance. It is needless to say that the reduction effected is only that produced by the air resistance ahead, and that the train resistance caused by flange friction produced by a side or quarterly wind is not reduced by the form of the train.

In the train, as now constructed, the tender is built up to the height of the car so that there is no break between the engine cab and the baggage car. The windows are set flush with the sides of the car. The sides of the cars extend down so as to nearly enclose the trucks and to prevent the air from impinging against them. The platform doors extend to the bottom of the steps, and are flush with the sides. The spaces between the cars are closed with flexible connections which accommodate themselves to all curves and the various complex motions of a train at high speed. The roof is arched and is perfectly smooth. The rear car tapers to a point. In the train now being tested nothing has been done to the engine, as Mr. Adams decides to show that the cars are the greatest violators of the laws of speed.

The second novel feature is the ventilating system. All the air for ventilation is admitted from the front end of the tender, where there is an absence of smoke or dust. It is carried along passages in the roof, which connect when the cars are coupled. From these ducts the fresh air is distributed through the train.

United States Consul McGinley at Athens writes, under date of May 14, 1900: "From reliable sources, I have learned that the Athens and Piræus Railway Company must, according to conditions in its franchise, adopt electricity as the motive power for its trains within the next three years. This road extends from the quay in Piræus to the business center of Athens, some 5 miles, three-fourths of a mile of the distance being through a tunnel under a portion of the city. A Belgian company which owns and operates a steam tramway between Athens and Piræus, via Phaleron, also wishes to adopt electric power for its trains; but how soon it desires to make the change has not been learned. Each road has a very large passenger traffic, especially in the summer season.

The Largest Electric Railway Company in Germany

Berlin, which, with its suburbs, has a population of 2,400,000 inhabitants, has a system of transportation which is the most complete in Germany, and ranks high compared with that in any other metropolis. The long distance traffic and that between the various steam railroad stations is cared for by the Stadt- und Ringbahn. This line has thirty-five stations. Its total length (measured as single track), is 65.17 km. (40.4 miles), of which 13.58 km. (8.4 miles) and fourteen stations, belong to the Stadtbahn. As the road is to a large extent elevated on stone arches through thickly populated city districts, great difficulties were encountered during construction, which easily explains the enormous capital investment of M.110,000,000 ($27,500,000) for its construction.

The most important institution for the local traffic of Berlin, and at the same time the largest undertaking of its kind in Europe, is the Grosse Berliner Strassenbahn, which has a stock capital of over M.67,000,000 ($16,750,000). On this road, including the Westliche und Sudliche Berliner Vorortbahn, 223,700,000 people were transported last year, and its cars, exclusive of trailers, traveled 22,300,000 km. (13,726,000 miles). About one-half of this road is operated by electricity, and probably not later than two years from now this will be the only motive power.

Besides the above there are other electric roads operating in Berlin, notably the Berlin-Charlottenburger Strassenbahn, the most important section of which was at first operated by accumulators only, but on part of which the overhead trolley has been installed. This company has also decided to supplant the horse on all its lines by electric power, and the order to do this has already been placed with Siemens & Halske. The same firm also constructed the Berlin Elektrischen Strassenbahnen, a portion of which (2.1 km) is operated by underground trolley, and another portion (16.3 km) by the overhead trolley.

On Oct. 21, 1899, another road, built by Schuckert & Company, was opened to the public. This road, which is 6.6 km. (4.1 miles) in length, carries freight as well as passengers, and is equipped entirely with the overhead trolley. The Stadt- und Ringbahn, already referred to, is the only existing elevated road in Berlin, but as early as 1891, Siemens & Halske submitted a design for an electric elevated road, and at the same time the Allgemeine Elektricitäts Gesellschaft formulated a plan for a connecting system of underground railways. The first proposition received Imperial sanction on May 3, 1893, for the section Warschauer Strasse-Nollendorf Platz, and work was begun in 1895 after much wrangling with the city in regard to the charter. The greater part of the road has already been completed, and the company formed for the construction of the road believes that the entire line from Warschauer Strasse to the Zoological Garden will be completed in 1901. Part of this line will be built underground, the other part elevated.

The permission to build a deep underground road has not been granted up to date, but the Company for the Construction of Underground Roads was able to celebrate on Sept. 1, 1899, the successful completion of the Spree Tunnel. This tunnel, which leads from Stralau to Treptow, is remarkable in many respects. It is the first underground passage which in its entirety is built in quicksand, and the first in Germany to be excavated exclusively by means of the breast shield. The electric road, which utilizes this tunnel, starts from the Schlesische depot, passes through Stralau, and ends at Treptow, and in the tunnel a speed of 13.5 km. per hour is attained.

Besides the surface cars several omnibus companies take care of the traffic of Berlin, and there is also a well organized cab system. At the beginning of 1899 there were in service 231 omnibuses and 8096 cabs. Omnibus and cab owners are at present experimenting with automobiles. Whether it will be possible to train a set of men so that they can operate these vehicles, especially heavy busses, without danger to the pedestrians, through the crowded streets of the Metropolis is a question which the future alone will answer.

To describe all these various means of transportation in vogue in Berlin, however, is not the intent of this article, but to consider only the most important road, namely the Grosse Berliner Strassenbahn. Nor will the history of this road, which was founded in 1871, be considered. Those who are interested in this aspect of the question are referred to a very excellent pamphlet on this subject, entitled "Twenty-Five Years of the Grosse Berliner Strassen-

FIG. 1.—MAP OF BERLIN, SHOWING THE LINES OF THE GROSSE BERLINER STRASSENBAHN

bahn," published by Bergmann, Wiesbaden, in 1898. The present article will be limited, therefore, to the introduction of electricity on the road, and to its status at the close of the past year.

The Grosse Berliner Pferdeeisenbahn A. G., as the present Grosse Berliner Strassenbahn was called until the beginning of 1898, made experiments with accumulator cars, the so-called Reckenzaun system, as early as in 1884 and 1885. The batteries, however, were not commercially reliable, so that after a short time the cars were dismantled and horses were again employed. Electrical experiments were then discontinued until soon after the opening of the Berlin Industrial Exhibition in 1896, when the managers of the road succeeded in obtaining permission from the city to introduce electricity, using the overhead trolley on several of its lines, which were being greatly crowded, due to the Exposition. The Union Elektricitäts Gesellschaft was asked to furnish fifty motor cars, and to equip several lines. The work was pushed vigorously, and when the Exposition was opened on May 1, 1896, a part of the system was in operation, the remainder being ready by June 29 of the same year.

The year 1896 might be called the experimental year for the introduction of electricity as a motive power on the Berlin street railways. The overhead system amply met the extraordinary demands made upon the road by the Exposition crowds, and was shown to be far superior to horse power for the transportation of large masses of people.

In December, 1897, negotiations leading to a definite introduction of electricity on the entire system of the Grosse Berliner Strassenbahn were finally brought to a close, due to the granting of the Emperor's consent, and motor cars were ordered at once, and the equipment of the line was begun. The execution of the work was intrusted to the Union Elektricitäts Gesellschaft, and was superintended by its engineer, Mr. Bjorkegren, who also supervised the construction of the Bremen and Hamburg roads, the latter ranking in size after that in Berlin, and well-known on account of its superior equipment and operation.

FIG. 2.—VIEW AT ALEXANDER PLATZ, SHOWING SPAN WIRE CONSTRUCTION

As the use of the overhead trolley was not permitted in the central and western portion of Berlin, it was decided to introduce the so-called mixed system on these lines, in which the battery is charged while the car is on the portion of the road equipped with trolley, and furnishes currrent for the motors on those portions where the trolley is forbidden. It should be added, however, that recently several of these branches originally equipped with the mixed system are now operated entirely by trolley.

On March 1, 1898, the Schöneberg-Alexander-Platz line was opened. It is 7.1 km. (4.3 miles) in length, 3.4 km. (2.1

miles) of which is operated by means of accumulators. On this line the double truck cars were first used. On May 11 followed the opening of two other lines, and in the following summer and fall four more lines, among which was the 14 km. (10.5 miles) belt line. As a result, the car mileage just about doubled.

In 1899 the electrification of the road was contiued with even more energy, so that at the close of 1899, nearly one-half of the city, and over one-half of the suburban lines, are electrically operated. The equipment is divided as follows: Overhead trolley, 105 km. (65 miles); accumulators, 16.5 km. (10.2 miles). Measured as single track the entire system now operated by electricity consists of 244 km. (151.3 miles), on 34 km. (21 miles) of which accumulators are the road. The Electric Works in each case supply the feeders, and the current is measured at the point of feeding to the trolley wire. There are a total of seventy-seven feeding points at present. At each two wattmeters are located, from which the current consumption is computed, one meter being placed there by the works furnishing the current, and the other by the management of the road. Fig. 12 shows a section box, in which two such meters of different types have been placed.

The several sections supplied with current are separated from each other during normal operation by section insulators, but they can be connected together by means of switches. The trolley wire is also separated into sections every 500 meters, these sections are ordinarily bridged by

FIG. 3.—TYPICAL STATION, BERLIN ELEVATED RAILWAY

used. When completed the system will comprise about 475 km. (294.5 miles) of track. In 1899, 13,910,000 kw-hours were consumed, and 22,278,835 motor car and trailer km. (13,812,678 car miles) were traveled. In these figures the results of operation of the Neue Berliner Pferdebahn-Gesellschaft, as well as the Westlicher und Sudlicher Berlinen Vorortbahnen have been included. The first named company was amalgamated with the Grosse Berliner Company early in 1900, and the same management operates all three roads.

By far the greatest portion of current used by the road is purchased from the Berlin Electric Works, the rest being purchased from Schöneberg Electric Works and the Charlottenburg Electric Works. From July, 1898, to July, 1899, Berlin Electric Works furnished 28,893,947 kw-hours, of which 35 per cent were used for the operation of a section cut-out. At crossings the section cut-outs are close together, and are never more than 100 meters from the crossing.

The trolley wire is of hard drawn copper, is 8 mm in diameter (No. 0 B. & S.) and is supported every 35 m to 40 m. The insulator is of the "West End" pattern, which was used here in Europe for the first time. Up to date, about 4700 tubular poles and 200 built-up poles have been placed in position, as well as 4000 rosettes with noise dampeners. As in most German installations, special care was taken to design and use poles which would thoroughly harmonize with their surroundings, and in Fig. 6 is shown the type of pole and arm most commonly seen in Berlin. The built-up type, also shown, is employed only in suburban districts and along sparsely populated streets. At certain points, special poles, with double candelabra, designed by

the royal architect, Schwechten, have been placed, as in front of the Emperor William Memorial Church. The designs of rosettes also correspond to the architecture of the buildings to which they are attached. That the noise dampeners which are used in connection with the rosettes work effectively, by the use of gutta percha insulation, is shown by the fact that of the 4000 rosettes installed, not more than thirty had to be removed, and this on account of a change about to be made on the building or because the building itself passed into the hands of owners who wished them removed.

The trolley wire is suspended 6 m (19 ft. 6 ins.) above the heads of the rails, but this distance is decreased to 4.5 m (14 ft. 10 ins.), the smallest permissible height under bridges and railroad spans, as shown in Fig. 11. The greatest span within city limits was necessitated at the Jannowitz bridge, where the distance from pole to pole is 80 m (262 ft.). In Fig. 5 is shown the method of suspension adopted in crossing the Colonnen bridge, the span being 100 m (328 ft.) in length.

The current is returned through the rails, which are bonded by means of copper in the usual manner adopted by the Union Company, and specially laid cables. The change to electric traction necessitated the replacing of a large number of rails, such as the Larson, Fischerdick, Haarman and 13-cm (5-in.) Phœnix by rails of more modern design. The standard rail used is of the Phœnix girder type 160 mm (6¼ ins.) high, with central web 11 mm (0.43 in.) thick. The lip is only 15 mm (0.6 in.) in width, and on new rails lies 3 mm (0.12 in.) below the running face. The lip was designed narrow, so that wagons passing over the rail would wear all parts of it equally, and thus a step formation would be prevented. The section finally adopted was the result of this company's long experience, and was rolled after the design of the royal engineer, Mr. Fischer-Dick. Most of the track is laid in concrete, and where this was impossible, on a bed of gravel, as shown in Figs. 56 and 7. The rails are nearly all joined by means of the Schmidt half-lap fish-plate, in which 50 cm (20 ins.) of the angle-plate is countersunk into one-half the rail-head at the joint. Since the beginning of 1898 the Falk cast rail-joint has been used on several portions of the road to a considerable extent, as has been described in these columns.

Besides the rails, nearly all the special work had to be replaced. That at present is mostly of the made-up type. The shortest radius of curvature is 16 m (53 ft.), the steepest grade is 4 per cent.

The underground conduit electric system is not in use at present on the road, nor is there a single instance of a simple accumulator system; the lines have the overhead trolley either on part of or on their entire length, or else the mixed system, where the battery furnishes current only along those portions where there is no trolley wire.

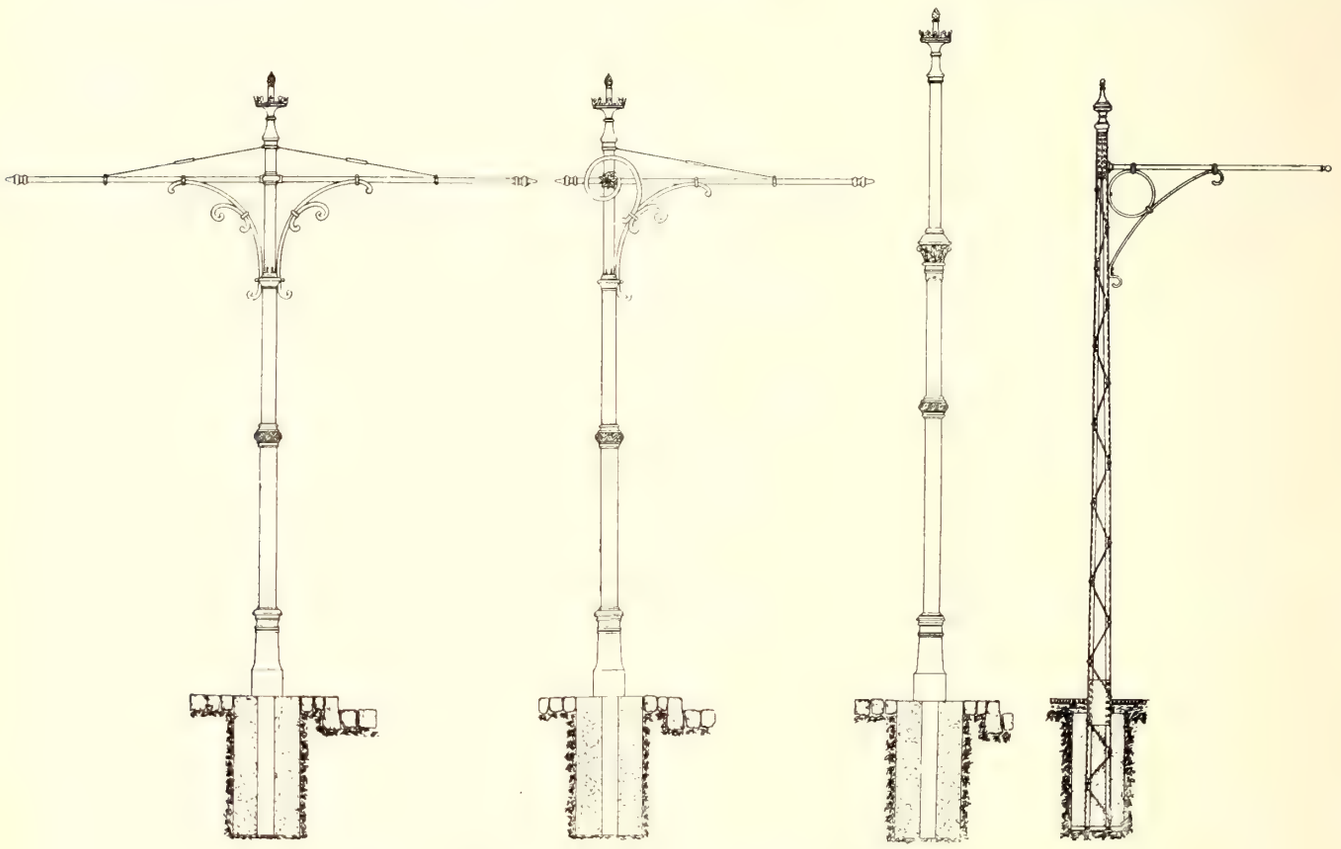


FIG. 4.—TYPES OF TUBULAR AND LATTICE POLES USED

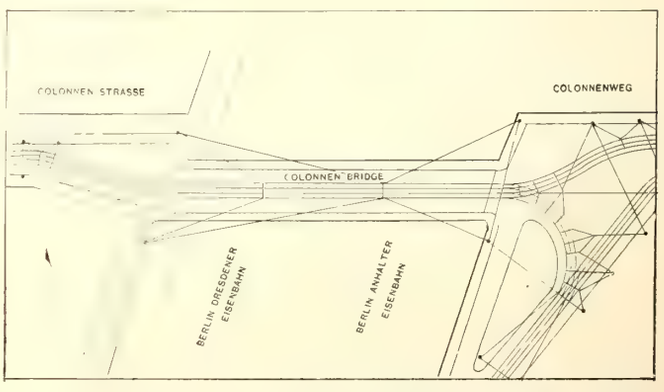

FIG. 5.—METHOD OF SUPPORTING TROLLEY WIRE WITHOUT POLES, ON COLONNEN BRIDGE (328 FT. LONG)

The accumulator system, which requires neither an expensive roadbed, like the conduit system, nor the overhead construction, is generally believed by the general public, to be the most perfect of all electrical systems, but, in addition to the weight, the acid fumes from the battery

have been found in Berlin to be offensive, in spite of the great care exercised in guarding against their escape. The separate cells must be completely cleaned out from time to time, and even then the experience in Berlin has been that the escape of gas cannot be avoided. Moreover, even in a comparatively new cell, the superoxide deposit which gathers on the plates causes a local discharge of the cell, thus greatly reducing its efficiency. Again, if the traffic is not quite normal, the time during which the cars are on the trolley sections is not sufficient to charge the cells so that they can carry the car over the sections where there is no trolley wire. It was also found on Dec. 11, 1899, in again using the accumulators for the first time after a heavy fall of snow, that they were far from satisfactory. All the stoppage and delays, the most serious which the road had encountered for ten years, were caused by the accumulators failing to meet the traffic demands. Besides, the expenses to maintain such a system are considerably increased. It was originally thought in Berlin that the accumulator (mixed) system would cost 6 pf. per km (2.4 cents per car mile) more than the overhead system, but it was found that this figure had to be increased 40 per cent. For an extensive overhead system the use of accumulators is rather a disadvantage, as the weight of the battery (2.8 tons on large cars) has to be transported along the entire distance as a dead load. On several lines where the traffic is densest and delays must be avoided at any cost, the city authorities have recently permitted the provisional installation of the overhead trolley, where formally its use was prohibited.

Another change necessitated by the adoption of elec-

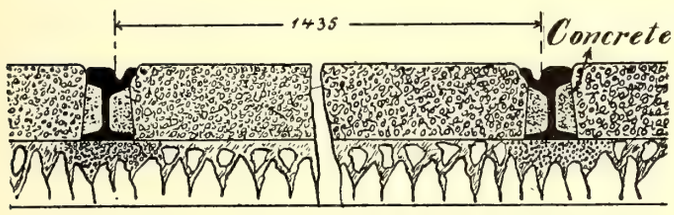

FIG. 7.—TRACK CONSTRUCTION IN MACADAM PAVING

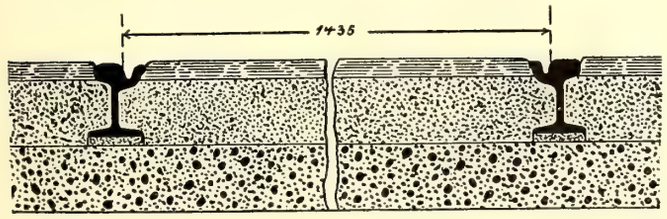

FIG. 8.—TRACK CONSTRUCTION IN ASPHALT

tricity as a motive power was the extension of the rolling stock. For the two lines opened in 1896 only fifty motor-cars were purchased, each being equipped with two motors of 13.5 hp, using 28 amps. At the close of 1897 the report of the company showed an ownership of only fifty-five motor-cars. One year later this figure rose to 375, 202 of which were designed for mixed service. At the close of 1899 the company owned 300 cars for mixed and 400 for the simple overhead system. For the complete road, as now planned, at least 1200 motor-cars will be required, 600 to 700 of which will probably be equipped with accumulators. Fifty cars were bought in America in order to obtain American designs; the remainder were of Ger-

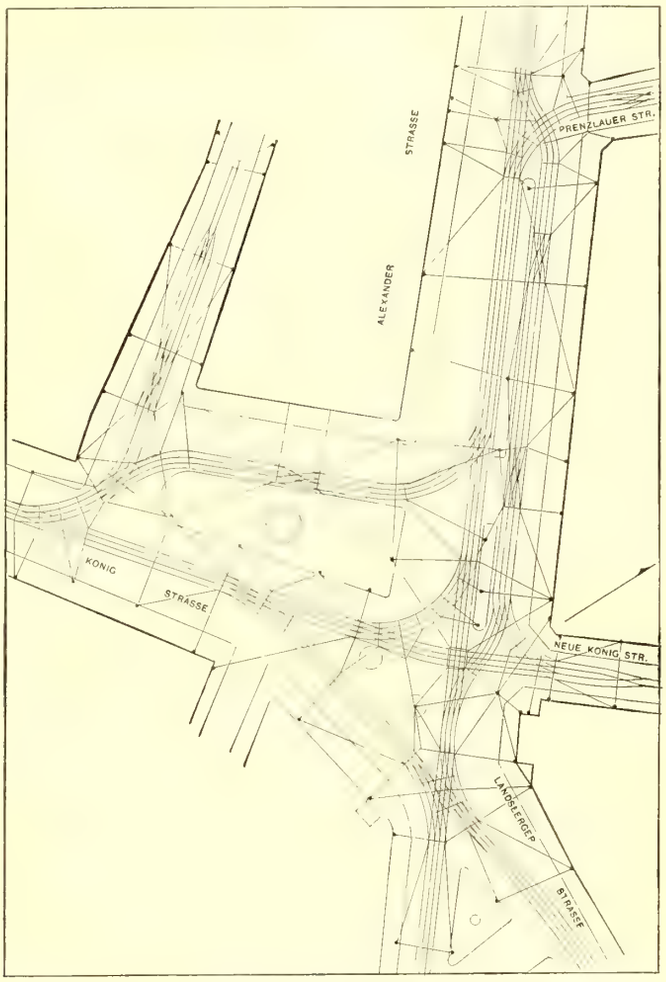

FIG. 9.—DIAGRAM OF OVERHEAD WIRING AT ALEXANDER PLATZ

man pattern and made in Germany. The two types differ mainly in the frame construction and the arrangement of the truck springs. The so-called St. Louis cars have cross seats, but these are not well adapted for Berlin street service, as the cars on several lines are only 2 m (6 ft. 6 ins.) in width, which is hardly sufficient for this type of car.

The trucks were furnished by the Bergische Stahl Industrie. The side frame for the single trucks, which are of the "model Berolina," are large steel castings united by flat iron cross-bars. The wheel-base on the single trucks is 1.750 m (5 ft. 9 ins.), and on the double trucks, 1.400 m (3 ft. 7 ins.) The double trucks were designed by Chief Engineer S. Peiser, of the road, who also drew up the plans for the car bodies and single trucks.

The new cars are equipped with two motors, which are protected, as are all the car-motors manufactured by the Union E. G., by a completely closed magnetic field. Each motor weighs 785 kg, has a capacity of 23 hp, and consumes 44 amps. The power is transmitted to the driving axle and cast steel wheels by means of gearing, at a ratio of 1:4.78.

The braking can be accomplished either by a hand or an electromagnetic brake similar to the General Electric brake, well known in America. The necessary current is

furnished by the motors, which are momentarily transformed into generators. The electrical braking of the trailers is accomplished by the current acting on an iron core, which, by means of a system of levers, operates the brake-shoes of an ordinary hand-brake. The latter can, however, also be operated by the motorman without affecting the electromagnetic device, so that these cars can be used either as horse cars or trailers.

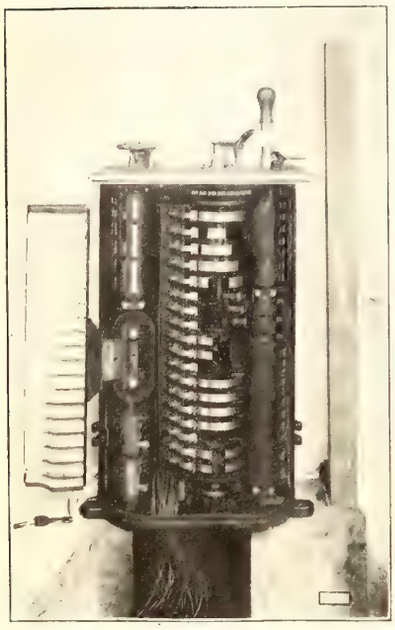

FIG. 10.—CONTROLLER WITH ELECTRIC BRAKE ATTACHMENT

The controllers for the simple trolley cars are of the series-parallel type, with electric brake attachment. Those for the mixed system cars are provided with a supplementary cylinder and small hand-wheel, by means of which the following combinations may be obtained:

1. The motors are connected with the trolley and the battery is being charged.
2. The motors are connected with the trolley and the battery is cut out.
3. The battery is connected with the motors and the trolley is cut out.

The trolley-pole is of the standard under-running type. In cars designed for the mixed system the pole may be let down onto the roof of the car.

The accumulators of Majert type, which were nearly all furnished by the Accumulatoren-werk Oberspree Niederschönweide, are situated under the two rows of seats in the cars. The first batteries were furnished by the Accumulatorenfabrik A. G., Berlin. The cells are provided with slugs, by means of which they are singly suspended on a wooden strip, which is a part of the car-body, and which is covered with hard rubber. Spilt acid can run off freely through openings in the bottom. Air is admitted into the accumulator space through four ventilating pipes in each corner of the car, which lead up through the roof and there end in a suction head. The double-truck cars contain 200 cells, which can furnish 30 amp.-hours at a one-hour discharge, and the single-truck cars contain 200 cells, having a capacity of 25 amp.-hours also if discharged in one hour. Although the longest portion of the road, along which there is no overhead trolley, is only 5 km (3.1 miles), the large types of accumulators have been chosen, as smaller ones would soon go to pieces, due to the large charging and discharging currents and the current consumption, which rises to a considerable amount during unfavorable weather conditions. The time for charging varies according to the time during which the battery was last discharged, from three to ten minutes. The charging current is 180 amps. at the beginning, dropping quickly to 100 amps., and then gradually decreasing in a straight line to 5 amps. The discharge current has an average value of 40 amps., but rises at times to 250 amps. These values relate to the larger types; for the smaller types the currents are about 70 per cent of the above. An ammeter is placed in the accumulator circuit, which shows whether the battery is charging or discharging.

FIG. 11.—PASSING UNDER BRIDGE WITH 14 FT. 10 INS. HEADROOM

There are ten incandescent lamps to furnish light in the cars connected in series of five each. They are supplied with current from the battery, 170 cells being necessary for that purpose when the trolley is in use, all of them, however, when they are being discharged.

The large cars have seats for twenty-eight, the small ones for twenty passengers, and there is standing room in each car for twelve people. All cars are equipped with a sand-box, and in the newly equipped cars the sand is thrown in front of the two forward wheels.

The first motor-cars were stored in the old, renovated car houses of the company, in the Manteuffel and Münberg Streets. In 1897 the depot in the Brandenburg Street was torn down and in its place a modern car house holding sixty-three motor-cars, and a small repair shop, was erected. During the course of the last few years a large part of the car stables were transformed into motor-car houses, and several new depots, designed exclusively for motor cars, have been constructed. A larger repair shop, in which one hundred cars may be repaired and 150 more stored at the same time, has been built in Ufer Street, where the new cars are also equipped with motors. In this connection it might be stated that the depots, which at the beginning of 1899 offered room for nearly 1100 horse cars and 6000 horses, will, within one and one-half years, all be transformed into houses for the housing and repairing of motor-cars. By the time the work of transformation is completed the company itself will own in round figures 1200 motor-cars, to which should be added one hundred motor cars belonging to other companies.

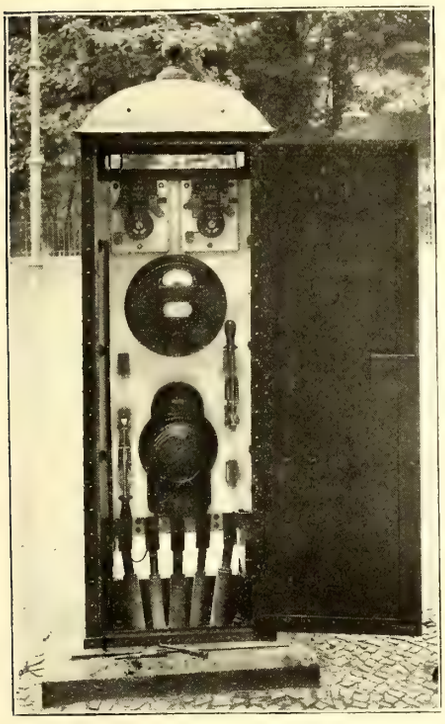

FIG. 12.—SECTION BOX WITH TWO WATTMETERS FOR MEASURING CURRENT FLOW FROM FEEDERS TO TROLLEY

In Berlin it is difficult to talk about a center of traffic; the various squares and markets rival with each other to become the most popular. Take, for example, the Alexanderplatz, from which emanate and through which cross twenty car lines with 150 cars an hour. A plan of this square is shown in Fig. 9 and a view of it in Fig. 2.

The Vincennes Exposition Railroad

[*From Our Regular Correspondent.*]

The Paris Exposition is divided, as most readers of this paper know, into two sections, this arrangement being determined upon by reason of lack of available space within the city limits. The annex is situated at Vincennes, about 6 miles distant from the main grounds, and is practically isolated, inasmuch as there is no adequate system of transportation between the two sections, and a single entrance ticket will not give admission to both. A partial solution of the transportation problem has been secured by providing a "temporary" double-track trolley road, which follows the line of the fortifications past the Bois de Vincennes, branching out into a loop at the main entrance to the Exposition grounds, and forming connection at one end with the Nogentais tramway system and at the other with the river steamboats. This line has been constructed by the French Thomson-Houston Company, under the supervision of its engineer, A. N. Connett, and was put in operation for the first time on May 12. It is doubtful whether it will be a paying property at first, as the Vincennes annex gives but little indication of becoming a really popular resort. The track races will doubtless draw a crowd; but during the show there will always be a

FIG. 2.—VIEW SHOWING POLES

FIG. 1.—TERMINUS OF VINCENNES ROAD AT ENTRANCE TO TRANSPORTATION EXHIBIT

general tendency on the part of the public to spend their time at the main Exposition grounds, where side shows and other amusements abound. The transportation and machinery exhibits are exceedingly interesting from an engineering and educational point of view, and the question has been raised as to whether it would not have been more just to exhibitors and to the thousands of visitors interested in these matters to have allotted space for such exhibits within the Champ de Mars grounds, instead of de-

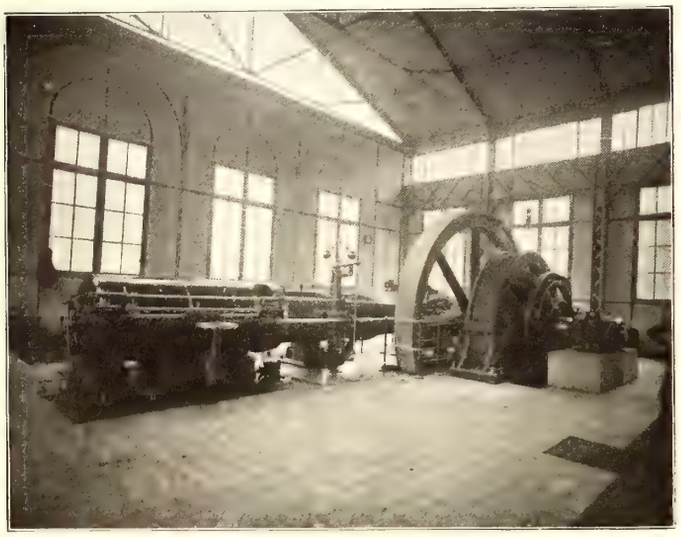

FIG. 3.—INTERIOR OF ENGINE ROOM

voting a large area to side shows and subordinating the true object of the Exposition to an apparent desire for pecuniary profit on the part of the administration.

The new electric line just inaugurated is intended as a connecting link between the Exposition annex and the various tramway lines which bring visitors to the city gates in the southeastern district, as, up to the present, there has

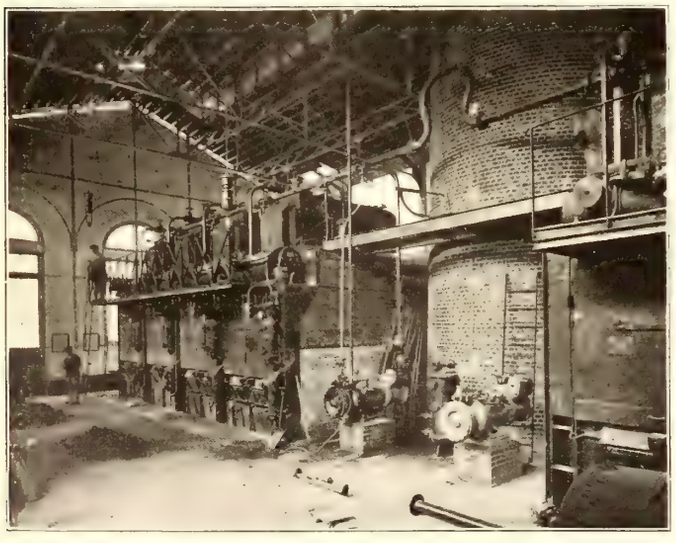

FIG. 4.—INTERIOR OF BOILER ROOM

been no street car service to the gate of Reuilly, where the main entrance to the Exposition of Vincennes is located. The cars are double-deck. It is intended to put twelve into service later on, but six only are used at the present time, as the line is less than 2½ miles long, and very few passengers are carried. On May 12, which was a Saturday, and, as above stated, the opening of the railroad to public use, the paying entries to the annex were only 759 for the entire day. Sunday brings out the crowds in every part of the city, and the paying visitors to Vincennes numbered on the 13th 6865, but it is doubtful whether there will be much passenger traffic on the new road on week days, at any rate until the season is further advanced.

The only point where the railroad passes outside the fortifications is at the gate of Reuilly, where a wide loop is made in front of the Exposition entrance. Fig. 1 shows one of the cars standing on the track at this curve, the entrance gateways being on the left and the Exposition buildings in the background. The roofed steel structure is the railroad depot where goods for exhibitors were unloaded; in the distance can be seen part of the Transportation Building, in which are the various types of locomotives built by French and foreign companies. Off to the right is the American Machinery Building. A double track is used on this loop, but the cars pass over both tracks in the same direction, the two lines being provided for the purpose of expediting the service at the gates, while two single tracks are laid in the cut-through fortifications.

A temporary car house has been erected near the upper end of the line, capable of affording sufficient shelter to the cars during the Exposition months. Near this building the track runs up a steep incline (Fig. 2), following the

FIG. 5.—CAR NEAR CITY WALLS

wagon road, and further on crosses the steam railroad of Vincennes, which has a station at the Place de la Bastille.

The trolley wire is carried on side poles, with flexible brackets. A large extension of the railroad system is contemplated, and for this purpose a larger power station is being built than would be necessary for this temporary line. The station is located near the northern terminus, in Rue des Laitières, where there are installed two 500-hp single-cylinder engines by Weyher & Richemond, running at 90 r. p. m., and two 1000-hp cross-compound engines by Farcot, of St. Ouen, running at 92 r. p. m. The generators are built by the Postel-Vinay Company for the French Thomson-Houston Company. Those coupled to the single-cylinder engines give an e. m. f. of 550 volts, and these machines are used for the temporary railroad. The larger generators furnish current at 750 volts, and are intended to supply power for the distant points of the Nogentais system, but motor-generator sets are provided, for cases of emergency, to transform the current from the higher to the lower voltage, or vice versa, as may be required. The two smaller engines are already in running order, but their condensing apparatus is not yet in use, owing to lack of water. An artesian well is being sunk just outside the power house, but up to the present time the

heavy clay bed has not been pierced, although a depth of over 300 ft. has been reached. The condensers are located below the engine-room floor, on the ground level.

Both types of engines in this station are represented at the main Exposition in the Champ de Mars Machinery Building, where Weyher & Richemond have two engines of 1000 hp, and one of 500 hp, and Farcot one of about 850 hp. The former company makes use of a very peculiar valve gear, which has apparently not the quality of simplicity, although at first sight there seems to be but little complication. The steam pressure is about 114 lbs. per square inch in the valve chest of this engine, and for the Farcot cross-compound about 128 lbs. in the valve chest of the high-pressure cylinder.

The boiler room immediately adjoins the engine room, and contains two batteries of four boilers each. Belleville water-tube boilers are employed, with automatic feed-water supply and one feed-pump per battery, these being placed on special masonry foundations between the two sets of boilers, at the base of the smoke stack, which is carried through the roof. Economizers placed above the boilers heat the feed-water as it passes from the pump. Steam is kept at a pressure of about 240 lbs. per square inch, in the boilers, and is held in auxiliary reservoirs in order to provide for fluctuations in load. This high pressure effects a considerable saving in space, as a low pressure of steam would require larger boilers; beneath the engine-room floor reducing valves are provided for bringing the pressure down to the required amount.

Behind the station are being erected two cooling towers, where the warm condensing water, falling in a shower from above and passing through a network of wooden rods, is cooled sufficiently to use over again.

The station is favorably located for furnishing power to the system it is intended to supply, being near the city limit and not too far from the center of the suburban lines. The switchboard, in addition to its four generator panels, will have thirteen feeder panels, supplying current to close upon 40 miles of track.

As the cars are of a somewhat novel type a few words of description will be of interest. Those used on the Vincennes line are of the double-decked type with bodies 14 ft. 11 ins. over all and inside 14 ft. $2\frac{1}{2}$ ins. The platforms are a trifle more than 6 ft. in length, making the cars measure about 27 ft. over the dashers. They are mounted on No. 21-E Brill trucks with a 7-ft. wheel base and have two G. E. 58 motors. These cars were fitted so they would be able to draw a trailer.

In the lower compartment longitudinal spring seats covered with plush are used. The brass arms divide the seats into spaces, two of which have room for two sittings and the remaining one for three. In respect to the space allowed to each person the French regulations are extremely minute and particular. A small fraction of an inch below the required amount reduces the licensed number of passengers. On the lower deck 480 mm, or 18 29-32 ins. are allowed for each individual, the measurements going from center to center of seat arms. Upon the upper deck 460 mm or 18 3-32 ins., are allowed per person. Although the French are as a race smaller than Americans, the space required in their regulations is considerably greater than that considered necessary in America.

The sash of the lower deck drop and the windows are protected by spring roller curtains. The platform is unusually large and the opening is in consequence quite narrow. The dasher closes one side of the platform com-

FIGS. 6-9.—VIEWS OF CARS, SHOWING UPPER DECK OPEN AND CLOSED

pletely. The stairway is of the ordinary European type of sheet metal, but is made with a high rail so that accidents are not likely to occur. A projection of the upper deck forms a sort of hood over the motorman. The upper deck or imperial itself is a novelty in every way. As shown in Fig. 6, it will be seen that there is a substantial canopy supported on strong posts. These are reinforced by a light tubular railing. For summer work the imperial or upper deck is open as usual. It has longitudinal seats divided by bronze arms as in the space below. The seats themselves are of slats with open spindle backs. At each end is a bulkhead, part of which projects outward over the platform, and in this projection a space is found for a seat at each end accommodating two persons. The door, as will

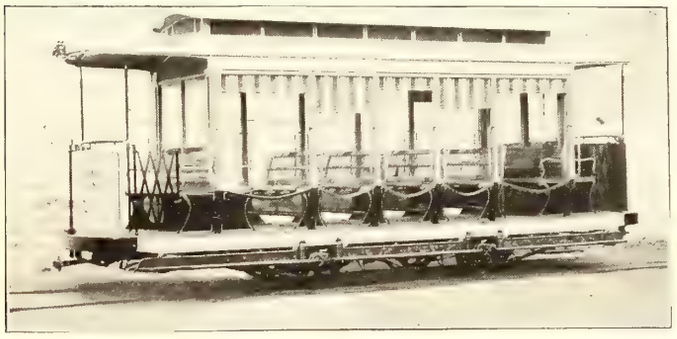

FIG. 10.—TRAIL CAR

be seen from Fig. 7, opens against the side of the car. This construction permits the seating of twenty-two persons on the upper deck, while but fourteen find seats below. The bulkhead is a valuable feature in the open car because it affords considerable protection in the case of wind or stormy weather.

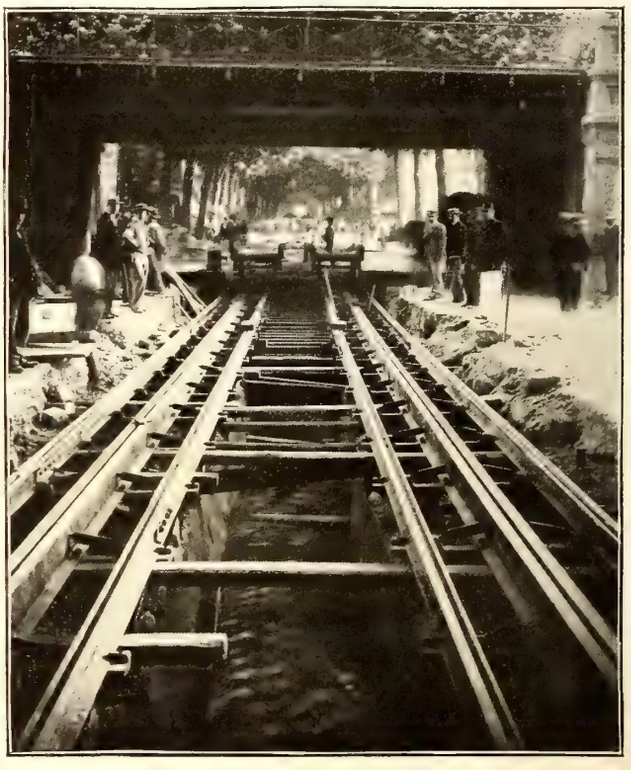
For winter service the whole imperial is enclosed by glass sash and panels as will be seen from Figs. 7 and 8. By the use of metal for panels the whole movable part is made very light so as to be easily handled, and is at the same time very strong. This form of construction, it is thought, has never previously been introduced. The metal for the panels is especially prepared and treated for this purpose. It makes the imperial quite as comfortable in winter weather as the other part of the car, and naturally increases its capacity. Beneath the seats on the upper deck a narrow monitor is introduced which increases the head room of the lower deck materially. One feature which will excite interest is the fact that the roof of the upper deck is made almost perfectly flat, and the trolley pole is carried by a light iron casting coming up from the main roof. This casting terminates in a bell, from which two gutters run to each end of the car. These gutters are seen in Fig. 6. In this the gutter can be seen in the center of the roof, the bell and the trolley tube being removed. In Fig 9 the tube is shown in place. Probably the practice is, when necessary, to pull the trolley pole down until it is flush with the roof. The long platforms are supported by angle-iron knees and the half elliptic springs on the ends of the trucks have a bearing not only on the body but on the platform. The truck with the motors weighs 9275 lbs., but the total weight of the car is only 18,825 lbs.

Apparently head room is at a premium, for these cars are scarcely high enough for an ordinary man. A six footer, even without his hat, has to stoop to pass into the imperial. The actual height in the clear is 5 ft. 6½ ins. On the lower deck it is 5 ft. 7¾ ins. The total height of the car from the rail is but 14 ft. 5¼ ins. With 33-in. wheels the platform is brought within 28 ins. of the head of the rail.

The trailers for these peculiar cars are not unlike those used in America on horse car lines, and are shown in Fig. 10. They are of the eight-bench open type mounted on Brill trail gear. The width in this case is so limited that it became necessary to introduce the peculiar form of grab handle shown. These are made in such a way that they do not extend outside the posts. The cars are 22 ft. 11 ins. long, have 4-ft. platforms and measure about 30 ft. over the dashers. Their width at the sills is but 5 ft. 7½ ins. and the seats are 5 ft. 11 ins. in the clear. The wheel base in this case, as in the other, is 7 ft. The seats are slat with open backs having ash spindles. The inside finish of the car is cherry with three-ply quartered oak head lining. The total weight of the car is only 7160 lbs. From the top of the sill to the step is but 13 ins., and the distance from the head of the rail is only a little greater.

Tramways of Nice and The Littoral

The towns along the Riviera from Cannes, France, to Menton, are being connected by an electric road. The entire system is being installed by the French Thomson-Houston Company, of Paris, which is directing all its energy toward completing the line at as early a date as possible. A 10,000-volt transmission line from Mescla, 30 km (18 miles) inland, supplemented by a steam plant



CONDUIT CONSTRUCTION AT NICE

at Nice will supply the power. When finished there will be 150 km (63 miles) of single track included in the street lines of Nice and the stretch of 50 km (31 miles) along the coast.

The former horse car system of Nice has been greatly extended and new lines have been added in and about the city. In the central portions, and especially on such streets as are traversed by the parades of the annual carnival, it has been thought desirable to build an underground conduit, but everywhere on the outskirts of the city the overhead trolley is used. The cars are adapted to travel over either system.

The construction of the conduit was delayed by last

winter's season, during which no work was allowed in certain sections, but it has since been pushed ahead night and day and, notwithstanding the numerous points where crossings of the lines occur with their accompanying elaborate special work, is almost entirely completed. The conduit is similar to the one built by the Thomson-Houston Company in Lyons and on the line from the Bastille to Charenton in Paris * and is well illustrated in the reproductions of the photographs taken during construction, which accompany this article.

Special attention has been given to the construction of the overhead line, the trolley wire running over the middle of the track as on American roads. The wire is 8.25 mm in diameter (No. 0 B. & S.) and supported either by means of transverse span wires or on long brackets from the poles. These latter are of the tubular type, but are so ornamented as to give quite a graceful appearance. In the city, wherever it has been possible, the use of poles has been dispensed with and the span wire has been attached to rosettes on the walls of the houses along the street.

The lines outside of Nice consist of the main line, which, starting from Cannes, traverses the cost to Menton, passing through Californie, Nice, Villefranche, Monte Carlo, etc., and by Cape Martin; and a branch line between Nice and the inland village of Contes. The latter is completely finished and will soon be in operation.

The Compagnie des Tramways de Nice et du Littoral, which is the operating company, has also secured the exclusive right to use the lines of railway recently built in Monte Carlo and described in the May issue. Menton, where the installation was last taken up, is expected to have cars in operation by the coming winter.

Double track is used entirely in Nice itself, but single track with turnouts is found at places along the coast. The gage is 1 meter. The rails are of the Broca or grooved girder type with a deep groove, and weigh 45 kg per meter (90 lbs. per yard). They are generally set on concrete and the joints are welded together by the Falk process. Granite blocks from the quarries of Saint Raphaël are used for paving.

The equipment of the power station at the Falls of Mescla consists of three 500-kw generators, each connected by a flexible coupling to turbines. The generators are twenty-pole, three-phase machines with stationary armatures and internal, revolving poles, having a frequency of 25 cycles per second and an electro-motive force of 10,000 volts.

DIAGRAM SHOWING TRANSMISSION SYSTEM

SUB-STATION AT NICE

On the 30-km transmission line connecting the Mescla station and the principal sub-station at Nice, there is a drop of 10 per cent. At Nice a portion of the current is transformed to 5000 volts, and retransmitted to two other sub-stations, one at Californie for supplying the line to Cannes and the other at Beaulieu for supplying the line to Monte Carlo.

As already mentioned, the sub-station at Nice contains the auxiliary steam plant. This includes two 700-hp double cylinder Corliss engines belted to the motor generators and two batteries of four boilers each. The latter are semi-tublar, having a heating surface of 185 sq. m (1991 sq. ft.) and a capacity of 20,000 kg (44,000 lbs.) of steam per hour. The diameter of the engine cylinders is 50 cm (19.68 ins.) and the stroke 1.21 m (47.64 ins.) They run at 100 r. p. m. There are two feed-pumps, one simple and the other compound, and a feed-water heater which uses the exhaust steam. The steam piping is mostly cov-

* See STREET RAILWAY JOURNAL, December, 1899.

ered with a non-conducting packing and the steam pressure is 10 kg per sq. cm (142 lbs. per sq. in.) There are two brick chimneys, one for each battery of boilers, 40 m (131 ft.) high and 2 m (6.56 ft.) internal diameter at the top.

POLE WITH LONG BRACKET

The illustration of the sub-station's interior shows the manner in which the engines are belted to the motor generators. These are two in number and consist of a 530-kw synchronous motor direct connected to a 500-kw compound railway generator. The synchronous motor receives the current directly from the Mescla transmission line at a pressure of 9000 volts. The generator has an e. m. f. of 500 volts at no load and 550 volts at full load. The speed is 300 r. p. m. The four-pole exciter for the motor, seen belted to the common shaft, is a 25-kw, 60-volt machine turning at 1100 r. p. m. There is one for each group of motor generators.

There are also in this station two rotary converters, for which the required e. m. f. of 340 volts on the alternating side is obtained by means of six static transformers. The three-phase transmission to Californie and Beaulieu at 5000 volts is supplied by six 55-kw transformers in two sets of three each. These lines may either be run entirely separate or thrown in parallel. Three 20-kw transformers reduce the pressure to 110 volts for running a small motor generator. This consists of a 50-hp induction motor, coupled directly to a 35-kw multipolar dynamo. The e. m. f. of the latter at 750 r. p. m. is 75 volts, and it is used as a booster on the line running to Contes. Oil insulation is used in the transformers.

The switchboard, part of which can be seen in the illustration, has altogether twenty-five panels. The principal ones are given in the diagram of circuits which accompanies this article, so that a detailed description is unnecessary. The arrangement of the instruments, etc., is according to standard practice. All connections are made by insulated cables on special porcelain insulators.

The machines are designed for a rise in temperature of 45 degs. C. (113 degs. F.), but will stand an overload of 25 per cent for half an hour, and one of 40 per cent for a few minutes without overheating or mechanical strain.

The station is lighted by direct current enclosed arc lamps on a 120-volt circuit. The current is obtained by using a 20-kw motor generator to reduce the pressure from 550 volts. This machine has a speed of 875 r. p. m. and is composed of a 550-volt motor direct coupled to a compound-wound dynamo.

The sub-station at Californie and Beaulieu, whose equipments are identical in all respects, are connected with the main sub-station at Nice by lead covered cables running in an underground conduit. These cables contain three wires, each 30 mm² in cross section (between Nos. 2 and 3, B. & S.) which transmit the three-phase, 5000-volt current from Nice. The sub-station at Californie is completely installed. The equipment consists of two 150-kw rotary converters and six 55-kw static transformers for reducing the pressure of the transmission line from 4300 to 340 volts. The rotaries have a speed of 750 r. p. m. and are 10 per cent over compounded. The switchboard has five panels, four of which are shown in the diagram. The one omitted is the line panel.

The feeders are nearly all underground. About the only exceptions are along the Contes line and for a short distance from the sub-station at Beaulieu—perhaps 10 km altogether. These overhead feeders are carried on the same poles as the trolley wire. They are 125 mm² (.194 sq. in.) in cross section. The underground system is made of armored cable 200 mm² to 400 mm² (.31 to .62 sq. in.) in cross section, which is carried from the sub-station to the points of distribution by the shortest possible paths. In order that the municipal regulations regarding difference of potential between the track and underground pipes may be strictly adhered to, a complete system of voltmeter or "pilot" wires has been designed and connects all the important parts of the line with the station switchboard. All danger from electrolysis is thus practically avoided.

When completed one hundred motor cars will be operated on the road, and if the service demands it, as many trailers as necessary. Twenty-two express or freight cars

LAYING A PART OF THE CONDUIT SECTION

and three electric locomotives will also be used. The motor cars are made in three models; those with but one compartment, those with two, for first and second class, to be used on the interurban line, and special parlor cars.

The electrical equipment of the cars consists of two G. E.-58 motors and electric brakes, controlled by B.-24 controllers placed at each end of the car. The cars are furnished with both trolley arms and underground contact plows so that they may be run at will over any part of the entire system.

CORRESPONDENCE

The Need of Heavier Wheels

BUFFALO, June 18, 1900.

EDITORS STREET RAILWAY JOURNAL:

We wish to call attention through the columns of your paper to a matter of importance in the service of wheels on electric street railways.

Owing to the increase in traffic, a number of roads in the larger cities have been rebuilding their equipment, using parts of the old equipment in the new construction. In the case of wheels and axles the lighter sections used under the cars and equipment are inadequate for the service demands of the new construction, even when eight wheels are used under one car, instead of four, as formerly, the new cars being, as a rule, longer than the old ones, and the use of eight wheels being necessary on account of the introduction of double trucks.

The additional strain imposed has been recognized in the case of axles by the substitution of axles 4 ins. and over in diameter, where formerly $3\frac{3}{4}$ ins. was the largest size used, but the weight and section of the wheels have not been correspondingly increased, and in fact have been practically decreased by the extra strain imposed in pressing them on the larger axles, which, of course, necessitates boring them out larger, and hence leaving less metal in the hub to resist a greater strain.

We are recommending a weight of not less than 400 lbs. for wheels 33 ins. in diameter, used under equipment where 4-in. axles and over in diameter are used. This allows for an increase of 25 per cent in the section of spokes and web, as compared with the 33-in. 360-lb. wheel that has been the standard for the past five or six years, but this increase of 25 per cent in the section only adds 10 per cent to the weight of the wheel, and as the railway company obtains increased scrap value from the additional metal the cost of the wheel is not materially increased.

It may be argued by managers of electric railways that the present section seems to be sufficient for the needs of service, and that a change might be considered when it proved insufficient, but this seems hardly a wise view to take if accidents are to be avoided. The conditions of service which may not cause accidents under ordinary temperatures are most likely to do so under continued low temperatures, and it is necessary to provide for maximum conditions, no matter how seldom they may occur.

There can be no doubt that the factor of safety has been decreased by the increase in the weight of equipment and speed at which electric cars are operated.

We are prompted to write you on these points in view of what appears to us as the great need of keeping the quality and character of the wheels for electric service up to the increasing demands of this service.

We believe that the officials of electric railways are in favor of such progress, but it is a question whether in the press of other matters they are always able to give the necessary time to this particular subject, and to appreciate the importance of it.

NEW YORK CAR WHEEL WORKS,
Pemberton Smith, Engineer.

Polyphase Transmission for Electric Railways

PITTSBURGH, Pa., June 18, 1900.

EDITORS STREET RAILWAY JOURNAL:

The following electric railways should be added to the list contained in your issue for June 2, as using polyphase apparatus for power transmission:

Name of company	Power transmitted
Long Island Railroad Company (Far Rockaway branch)	267 hp
*Sanford & Cape Porpoise Railway Company, Sanford, Me.	667 hp
Utah Power Company, Salt Lake City, Utah	2000 hp
Youngstown Park & Falls Street Railway Company, Youngstown, Ohio	533 hp

*Uses a 500-kw double-current generator.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY.

Electric Heaters

NEW YORK, June 12, 1900.

EDITORS STREET RAILWAY JOURNAL:

We have noted in your June number an editorial on the subject of electric heaters for street cars. We must take exception to some of the statements made, as we have placed upon the market during the past five years nearly 50,000 electric heaters, but up to the present time we have never heard of one single instance where a Gold electric heater has burned or even scorched a dress; neither is there a record of any one of these heaters ever having short circuited or given trouble in any way.

In the Gold electric heater the circulation of air through the resistance coils is so rapid that the flow of warm air from the top of the heater, while large in volume, is moderate in temperature, and is never so intense as to unduly heat the front casing. In regard to short circuiting, one look at the construction of the Gold electric heater will thoroughly convince any one that it is absolutely impossible for a short circuit to take place within the heater, for the reason that the resistance coils are supported in such a way that should any accident occur, it would be impossible for them to leave their supports.

The place for an electric heater in a street car is just where the great majority have been applied, that is under the seats and set back into the panel board. A heating system like the one suggested in your article, intended to carry the warm air up back of the seats and heat the windows and incidentally the necks of the passengers, leaving their feet cold and the floor of the car wet, would be entirely impracticable. The consumption of current in electric heaters has been reduced to such a point that railway managers on all of the large systems throughout the country appear to be entirely satisfied on this point.

We might add that in a test recently made with our Gold improved electric heater an overload of 25 per cent was put through the heater, and the casing was entirely covered with damp cloths. The current was left on then one full hour, and at the end of that time there was not the slightest indication of burning or discoloring in any way.

No heater in actual practice is ever put to such a severe test as the one mentioned. It simply shows that when our heaters are used, no fear need ever be entertained of burning the clothing of the passengers or of the heater coils short circuiting.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our news columns.

All matters intended for publication in the current issues must be received at our office not later than Wednesday of each week.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

The equipment of towns and cities with the trolley system of tramways in England is certainly eliciting a great deal of attention from the residents. An interesting letter regarding the color of the poles from a writer signing himself "Artist" has recently been published in a paper of a town whose roads have lately been electrically equipped. This artist calls attention to the color of the poles, and advocates a grey-blue color as being particularly suitable for the purpose on account of its being what he calls a "retiring" color. At the same time he also advocates painting the cross arms blue, as they are often seen against the sky, and will be less noticeable if painted this color. He also points out that in many of the streets in his town the houses are of red brick, and that perhaps in that part of the city the poles might be painted a similar color. It is curious to note the interest which these details have elicited, though we are of opinion that the various colors which this artist suggests, instead of making the poles less conspicuous, would have the very opposite effect, and we think that this may be safely left to the engineers in charge of the work, who undoubtedly are familiar with the proper colors to give poles from their experience in other towns.

It appears that Russia is to be invaded by American manufacturing capital, which will shortly establish large plants for the production of electrical apparatus, pumps, sewing machines and other American machinery of all kinds. The value of American special machines in reducing the cost of manufactured product is coming to be generally recognized in European countries, as can hardly fail to be the case, considering the enormous difference in costs brought about by their use.

We chronicle elsewhere the establishment by the employees of the Camden & Suburban Railway Company of what has been called a "Discussion Night," to be held once a month. The plan has the cordial co-operation of the officers of the railway company, who have presented a room to the employees for holding their meetings. This plan, which we think has been, and is, in operation on a few other roads in the country, of meeting once a month and discussing problems in electric railroading, is a most desirable one. The association not only proposes to discuss electrical and mechanical problems, thus making the operation of electrical apparatus much simpler to the user, but also to take up the operating problems upon which there is much less literature or opportunity to study from text-books than in electrical apparatus.

The general practice in steam engineering in this country is to depend entirely on the cut-off, as controlled by the governor, to vary the admission of steam in the cylinder with changes in the load. In this respect American practice differs from that in England, and in some other foreign countries. There, throttling for low loads is extensively practised. That is, the cut-offs of the engine are controlled in the usual way, but where the engine is running considerably under load the throttle is partly closed by the man in charge. It may be news to some of our readers to learn that this practice, especially with compound engines, has given a very high efficiency, as compared with engines operating under full steam pressure with all loads. There are several reasons for this. In the first place, with a fluctuating load such as in street railway service, it is exceedingly difficult, with full steam pressure, to maintain an equality in load between the high and low pressure cylinders at low loads, consequently the low pressure cylinder becomes a drag on the engine. Again, where throttling is practised, the steam after passing the throttle, is in a certain sense superheated. That is, while its temperature may not be higher than that before it passes the throttle, there are more heat units in the steam than are required for saturated steam at the lower pressure at which it is admitted to the cylinder. This fact adds to the economy of the engine in producing less cylinder condensation, which is a considerable loss in all engines. Again, the differences in terminal temperatures in the high-pressure cylinder at low loads will be less, in which case we should expect to obtain better steam consumption results. These arguments, at any rate, are those used by the advocates of throttling. While the advantages may seem somewhat hypothetical, it is interesting to note that the method is being tried in this country. In one station, for instance, the equipment consists of a number of 300-hp high-speed engines, each belted to a generator, and one 1250-hp direct-connected compound Corliss engine. Ow-

ing to its lower economies at low loads, the all-day efficiency of the 1250-hp engine has been found to be 10 per cent less than that of the 300-hp engines, which, owing to their small size, can be thrown in and out of service as required, so that those running can be worked up to their full rating continuously. The owners of this station are going to try throttling the large engine at low loads, and hope to obtain better results.

The decision by the managements of the Boston Elevated Railway Company and the Manhattan Elevated Railroad Company, of New York, to adopt the multiple unit and double unit systems, respectively, for the operation of trains on their elevated roads, probably sounds the knell of the "locomotive" for high-speed city and suburban transportation, both in this country and abroad, and it is safe to say, we believe, that nothing but distributed motor systems will hereafter be considered, unless by ultra conservative or poorly informed engineers and capitalists. The chain of logical sequence in arriving at "distributed motor" systems as the only solution to the rapid-transit problem is as follows:

1. The conditions are that immense numbers of passengers must be moved at the highest possible speed, on trains which follow each other as closely as is consistent with safety, over lines where stations are close together.

2. To produce high speed under these conditions, rapid acceleration is a necessity.

3. The rate of acceleration is limited by the "traction" of the driving wheels. This "traction" can be increased by increasing the weight on a small number of drivers, or by increasing the number of drivers.

4. The limits of possibilities on the first, or locomotive, plan are soon reached—by the second, or distributed motor plan, the limits are far ahead of the necessities, since 100 per cent of the train weight can be placed upon the drivers if desired.

5. With modern rapid transit, the locomotive system is and will be a failure. The distributed motor system, on the contrary, can, and will, revolutionize city traffic.

6. Incidental savings and advantages of great aggregate value are also found in the improved system—such as economy in switching, ease in maintaining schedules, simplicity in running branch line service without transfers, and economy in current consumption.

During the past two years the opinions of engineers have been completely reversed, and those who laughed at the idea of there being any economy or advantage in the distributed motor systems are now their most ardent advocates.

The world is now witnessing in Paris the complete paralysis of a city transportation system twenty years behind the times, and which, under the strain of a temporary increase in traffic due to the Exposition, has wholly broken down. This result is due less to lack of enterprise on the part of private capital than to absurd "regulation" and obstacle making by the French national, and the Parisian local governments. These have made determined and hitherto successful, opposition to the one great improvement—electric traction—which would make it possible to carry ten passengers in Paris where one is now accommodated. Does this seem an exaggeration? We have only to point to the history of transportation in New York City during the past twenty years to see how tremendous has been the increase in carrying capacity which electricity has brought. We could forgive Paris, however, for her "conservatism" in not permitting electric railways to invade her streets, particularly as the outside world shares in the beauty of Paris as it is, without suffering greatly, except for a few days or weeks in the year, from the inconveniences which Parisians themselves are forced to stand permanently; but it is more difficult to overlook the absurdity of the "*complet*" system which paternalism forces upon its sons and daughters in the mistaken idea that they are benefited thereby. As this "*complet*" system is occasionally held up in American city councils to the admiration of the people in an effort to further "no seat, no fare" ordinances, a few words as to how it works, both now and under ordinary circumstances, may not be out of place.

Imagine an omnibus or street railway route passing from the heart of Paris to a suburb, and lined with little waiting stations 500 to 1000 ft. apart. A bus takes its load at the city terminus, the passengers filling all its seats but five, let us say. Merrily it starts off on its journey, and in due course of time reaches the first waiting station. There it finds ten passengers anxious to embark. Each of the ten on entering the station has received a numbered ticket, and the five only who entered first out of the ten are permitted to take the bus. The load is then "*complet*," and a white card bearing that word is hung on the outside. If at the next station no one wishes to get out, the bus rolls on, leaving fifteen or twenty disappointed people in its wake, hoping that they may be more fortunate with the next arrival.

Now, in ordinary seasons, when no extra crowds are in Paris, a way passenger need not ordinarily wait more than from ten to twenty minutes on the less popular routes for the privilege of boarding a bus or car, and perhaps during the lighter traffic hours of the day not even so much. Now, however, it is a matter of hours, rather than of minutes, even to secure a seat at the city terminus of the suburban lines, while it is utterly impossible at almost any time to get on board at the way stations other than at transfer points. In a single case recently a trip to the Transportation Building at Vincennes, and return, required seven hours of waiting and riding together.

What wonder is it, then, that all Paris, native as well as foreign, has risen in arms against the transportation system, has mobbed the buses, the waiting rooms and the company's offices, has refused to submit to antiquated regulations, and is insisting upon better facilities. No such system would be tolerated in America for a moment, and if the experiment should sometime, by some mischance, be tried in an American municipality, the people would rise in their majesty after a day's experience of it, and would demand as a valuable privilege the right to again hang on to the much-abused strap, refusing utterly to wait even five minutes for a car which is not "*complet*."

The Starting of Rotary Converters

The increasing use of alternating-current transmission and rotary converters for the delivery of current to street railway lines warrants a discussion of the special problems of such work in these columns. The rotary converter,

while a most satisfactory machine when operating at full speed, is, so far as its alternating-current supply is concerned, a synchronous motor, and is consequently subject to the difficulties of starting inherent in this type of machine. Wherever possible, it is best to start rotary converters as direct-current shunt motors. This, of course, necessitates some source of direct current other than the rotary itself, since the latter will not transform alternating into direct current until it has reached full speed. With a storage battery such a source is always available, and with two or more converters in one sub-station any one can be started by means of direct current after any other is in operation. With continuous 550-volt copper from one station to another, the rotaries in a sub-station can be started up by direct current, transmitted from another sub-station or from the central power station over the trolley wires and feeders, the current drawn to start a machine at the sub-station not being sufficiently large to cause an excessive drop between stations if there are no cars on the line trying to start up at the same time. When starting up in the morning, if direct current is available at one station, this is a very satisfactory method, but if a shutdown occurs during the day this method of starting is likely to be interfered with by cars attempting to start up at the same time and pulling down the voltage at the unstarted sub-station to such an extent that the rotaries cannot be brought up to speed.

For starting by means of direct current there is required a starting rheostat in the circuit from the armature to the direct-current bus-bars, just as though the machine were a direct-current shunt-wound motor. Generally this starting rheostat is shunted around the negative main switch. In this case the negative terminal of the field of the machine should be connected to the negative bus-bar and not to the negative brush of the machine, so that the field may get full voltage before current is admitted to the armature. By closing the positive switch, the circuit breaker and the field switch, the field becomes excited, and by closing the path through the starting rheostat and cutting out resistance the armature is brought up to speed just as is any direct-current motor, after which the negative main switch can be closed, short-circuiting the starting box, and the machine can be synchronized and switched into the alternating-current circuits in the usual way.

Another satisfactory way of starting rotary converters is to switch them all into circuit before the main generator is started, and to excite the field of the latter to full strength before starting it, in which case the rotary converters will all speed up in synchronism with the main engine and generator. This requires that the exciter be separately-driven independently of the main generator. This method is applicable to starting up in the morning, but is, of course, not applicable to throwing on additional rotaries while the plant is running. In cases where there is a rotary converter in the central generating station this one rotary can be started up in the morning in this way, the others in outlying sub-stations being started by means of direct current from the central rotary transmitted over the trolley wires.

If it is necessary to start rotary converters with the generating plant running at full speed and with no direct current available, the above methods cannot be used and some means must be provided to start them by means of alternating currents at full frequency. In general, two methods are used. In one of these, a small starting motor of the alternating current induction type, which starts up readily from a standstill, is coupled to the shaft of each rotary converter. These starting motors bring the rotaries up to speed just as would any external source of power, the rotaries building up their own fields from residual magnetism, just as do any mechanical-driven direct-current generators. The rotaries are then synchronized and switched in to both the alternating and direct circuits in the usual way. Another method is to start the rotaries by switching the alternating currents into the armature through the usual collector rings, the fields of the rotaries being unexcited. A considerable rush of current follows, generally much more than full-load current, setting up induction-motor action on the field poles, which gives sufficient torque to overcome the friction of the machine and bring it up to speed. If alternating currents at full voltage are thrown on in this way, the rush of current is so great as to seriously pull down the voltage, unless the rotary is small as compared with the generator and line carrying capacity. For this reason transformers designed to give an extra low voltage for this purpose and termed "compensators" are usually put in.

The alternating currents in the armatures of the rotaries, when these are at standstill or are running at low speeds, set up alternating magnetism in the field magnets, inducing very high alternating e. m. f's. in the shunt-field magnet windings. The many turns of the shunt winding of a 550-volt rotary will receive such a high e. m. f. in this way that it is customary to use what is called a "break-up" switch to separate the several coils of the shunt-field winding from each other so that the voltages set up in all of the coils will not be added to each other to strain the insulation at the ends of the winding and cause a breakdown of the insulation and ground on the frame. The alternating magnetism in the field also sets up an e. m. f. in the series field coil, which tends to send a powerful current through the shunt round the series coil. To prevent this a switch is inserted in this shunt so that it may be opened at the time of starting.

This method of starting is perfectly satisfactory as long as the transmission line is supplying no other load calling for steady voltage. If the rotary converter to be started is a small one and the capacity of the line and generators is comparatively great, it works all right; but, otherwise, it overloads the line, and any other load upon it gets a bad drop of voltage. For this reason when there are two or more rotaries in a sub-station they should be fitted with direct-current starting boxes. With this means one may be started in the morning by means of alternating currents at a time when there is no load to be disturbed; the other or others may then be started by direct current without trouble from overload. If there are two or more sub-stations taking power from one generating station and the attempt is made to start up in the morning by means of alternating current applied to the rotaries at full frequency, one sub-station may be synchronizing and another will throw in and draw such an overload as to pull down the speed of the generator and prevent the first sub-station from getting in synchronism. A far better way is to either start all the rotaries with the generator or to start one rotary converter at one station by this means or even by the use of alternating current at full frequency, and from this rotary converter transmit direct current to the other sub-stations for starting purposes.

Transportation Building at the Bois de Vincennes

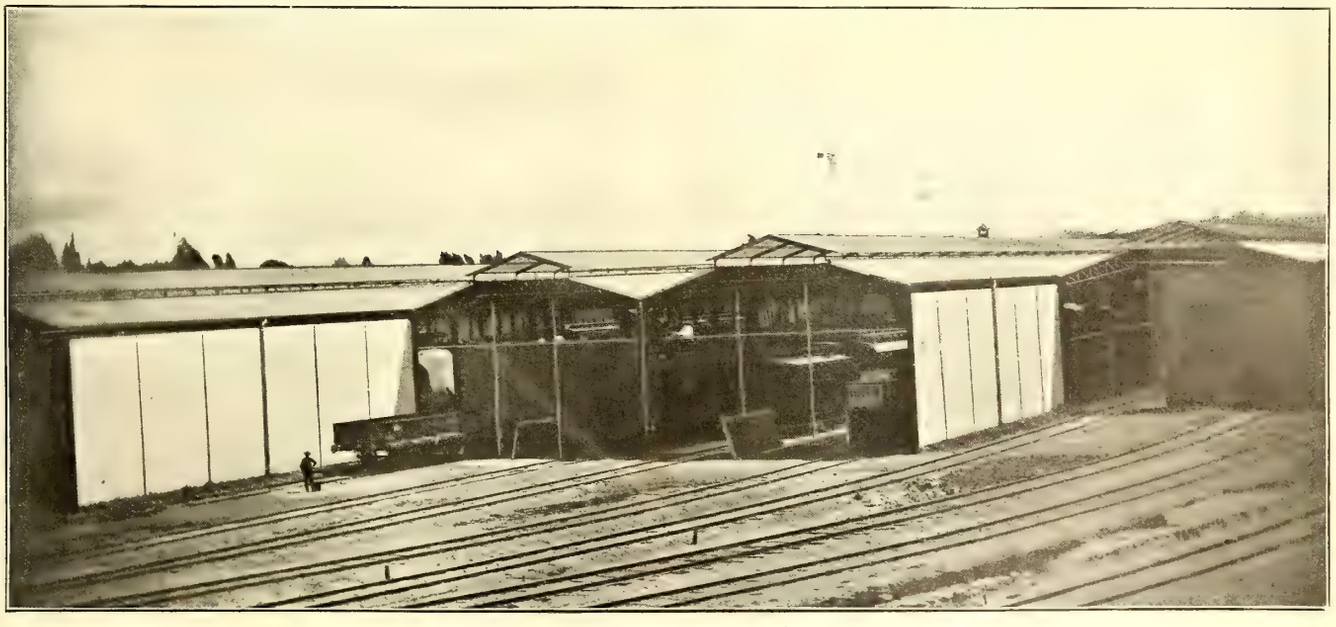
[*From Our Regular Correspondent.*]

Allusion has been made in another article to the startling contrast between the superb Palace of Transportation on the Champ de Mars, and the Transportation Building at the Bois de Vincennes section of the Paris Exposition. In more than one respect the contrast illustrates the promise and the performance, the plan and the realization, of this really great and beautiful World's Fair. The limited space on the Champ de Mars and the Trocadero Hill was given out so lavishly to meretricious, salacious sideshows that there was no room left for the main Exposition or for objects of real value and merit. The money available for a Transportation Building was expended so generously on the one in which very few appropriate exhibits can be found that when it came to provide for the overflow, nothing more could be done than to erect the meagre, cheap sheds which are here shown, and which, as a general thing, can be reached only after the expenditure of considerable time, money and patience. Yet even this division, exasperating as it is, does not quite represent the confusion and muddle, for street railway apparatus is to be found—when found—in no fewer than five different parts of the show, and there are not less than six distinct, different sections in which transportation exhibits, generically considered, have been placed. There may be more, when all the exhibits have finally got into place. If this is borne in mind, with the additional fact that, up to the middle of June, two months after the Exposition opened, no transportation catalogues or lists were obtainable, it will be seen that the mission of the man bent on studying the subject for himself or others is not yet an altogether grateful one.

The Transportation Building at Vincennes is just across a small lawn from the American Machinery Hall, and is best reached by taking the steamboat down the river and the Thomson-Houston street car line up the hill to the main entrance gate, where the line circles. As will be observed,

FRONT OF TRANSPORTATION BUILDING, VINCENNES

the building is in reality a series of low train sheds. Along the white front the names of the different countries are painted, for guidance, and within are a large number of tracks connecting with the steam railroad network of France, so that cars, locomotives and rolling stock of standard gage have been able to come right in and be switched and shunted into position. For pieces not of standard gage special sections of track have been set up. Between the tracks extend long stretches of plank platform up and down which visitors move in inspecting the exhibits. As a general thing, heavy rolling stock has been placed at the inner end of each track and the street cars at the outer or receiving end. Outside the building are other receiving tracks for freight cars, etc. The United States has inside the building about 22,000 square feet, of which 16,000 square feet is net, and and a little over 400 feet of the exterior track.



TRACK ENTRANCE TO TRANSPORTATION BUILDING, VINCENNES

Outside the group of electric locomotives, most of which

are now in position and have had their wrappings taken off, the most interesting and ambitious exhibit is probably that which is intended to illustrate the Budapest underground road. Not only is one of the regular cars shown, but there is a complete cross-section of the road itself, and one of the neat and pretty stations, with the white tiling,

TEMESVAR VASUT TROLLEY CAR

AUSTRO-HUNGARIAN TROLLEY CAR

STEAM LOCOMOTIVE, LYONS-NEUVILLE

stairway, steel columns, platform, etc. The car is also complete in every respect, and carries its bent-bow trolley, while the overhead and track wiring and bonding are also illustrated in detail. If one were to visit Budapest, it would not be possible to see much more. Incidentally, it may be mentioned that elsewhere in the building Austria-Hungary has also two other neat exhibits in the shape of one of the regular street cars in use at Temesvar, showing a very solid vestibule at each end for the motorman; and a fine Prague trolley car.

The French exhibit of street cars and tramway locomotives is quite extensive, but without a very close examina-

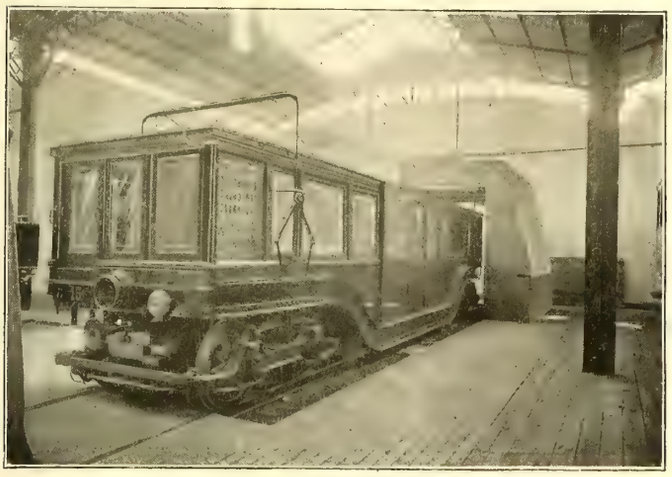
BRILL SNOW SWEEPER

CAR CHEMINS DE FER NOGENTAIS

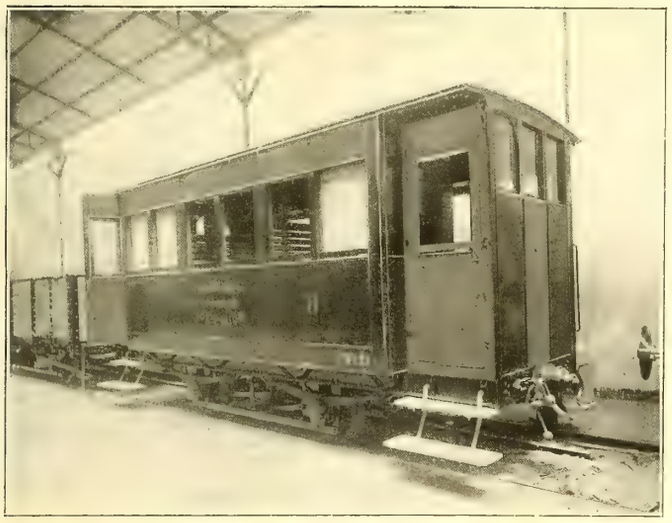
EXACT REPRODUCTION OF BUDAPEST UNDERGROUND ROAD AND STATION

tion it is rather hard to say where the distinctive French part in the exhibit begins and the American part ends. American trucks and cars of such types as the Brill and Peckham are freely used in Europe, and not less freely plagiarized; and on all the newer work the imprint of American ideals and practice is to be detected, in virtually every branch of design and operation. There are, how-

ever, many vehicles unfamiliar to the American visitor, such, for example, as the steam locomotive from Lyons, or the narrow gage, rack rail electric locomotive from the



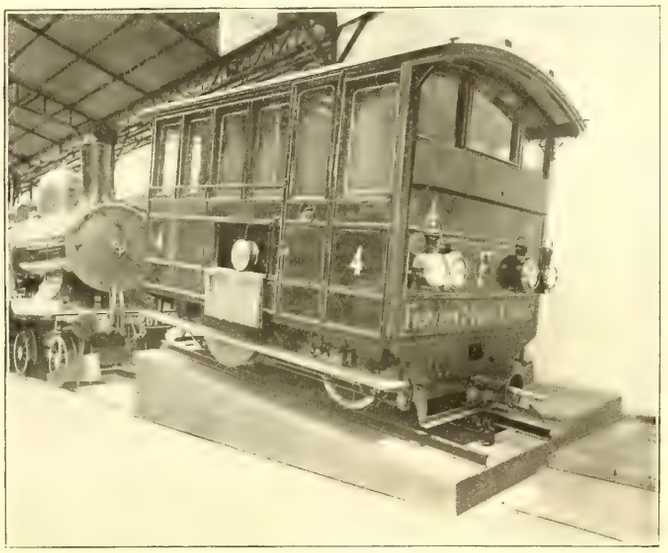
BUDAPEST UNDERGROUND CAR AND ROAD



CAR OF TRAMWAY DEPARTMENT DE L'AUDE

BASTILE-PORT RAPP, DOUBLE-DECKER

Fourviere & Ouest-Lyonnais for very stiff hill climbing. The tramway car of the Department de l'Aude, for second class, is also interesting, if only because of the wonder it engenders at the courage exhibited in trying to operate a tramway line on a steam road basis, with a complicated tariff and all its necessary attendance and bookkeeping. The French exhibit includes also a number of double-deck



ELECTRIC LOCOMOTIVE FOR HILL CLIMBING, FOURVIERE OUEST LYONNAIS

cars of different types, for steam, electricity or compressed air; but these only supplement several shown at the Champ de Mars, as illustrated in the June JOURNAL, or as treated in detail in a separate article on the Vincennes special trolley road.

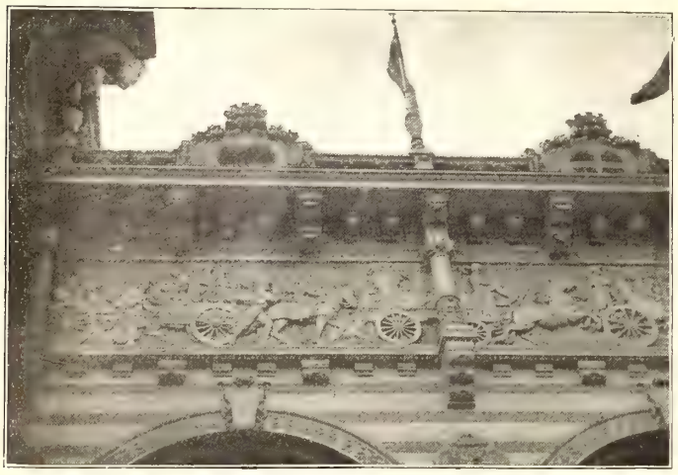
Decorative Panels, Transportation Building, Champ de Mars

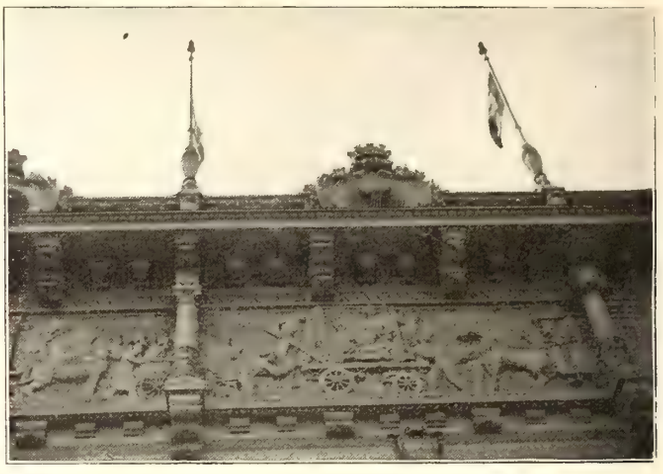
Reference was made in the June issue of the STREET RAILWAY JOURNAL to the series of decorative panels along the facade of the Transportation Building, in the Champ de Mars section of the Paris Exposition. These have at-

FRIEZE AT ENTRANCE TO TRANSPORTATION BUILDING, CHAMP DE MARS

tracted a great deal of attention and admiration, and we are glad now to be able to show a few of the principal groups relating to recent and relatively modern methods of travel

and the transportation of freight. No fewer than twenty of these panels ornament the long front of the building, and as each is about 15 ft. long and 9 ft. high, they attest the industry of their sculptor, Mr. Allar, even if they were not wholly successful from an artistic standpoint or from that of an engineer. But their designer is to be congratulated on the ease and grace with which he has grouped his figures and vehicles and given to all of them flowing lines that not only please the eye, but convey very forcibly the sense of activity and movement. The tableaux reproduced herewith deal more particularly with the achievements of the past century, and in three of them the omnibus, the tramway, the trolley car, the automobile and the bicycle play a very prominent part. As will be noted, the set shown begins with an abundant use of the power of man and beast; but in the finale, the horse has entirely disappeared, and the use of the bicycle is attributed solely to purposes of sport and recreation. Beneath these panels are twenty colossal figures in high relief, ten each side of the main portico, of which a view is here shown also. These "heroic" size figures, one on each pillar face, signed with different names, are intended to represent the motorman, the stage driver, the navvy, the signalman, the train conductor, and others of the leading types of men employed in the construction and operation of street car lines, railroads, bridges, etc.; and, on the whole, a most dignified effect has been happily produced. As a matter of fact, the Transportation Building is the most elaborately treated of all the large palaces on the Champ de Mars, if we except the Chateau d'Eau, which is not a palace, but a mere front to the water supply and condensing system of the power plant. In fact, the contrast between the handsome building devoted to transportation in the main Exposition and the primitive car barns bearing the same designation at Vincennes could not very well be sharper.





DECORATIVE PANELS, TRANSPORTATION BUILDING, SHOWING PROGRESS IN THE SCIENCE OF TRANSPORTATION

Third-Rail in the B. & O. Tunnel

After a long and thorough test of the overhead trolley, the Baltimore & Ohio Railroad Company has decided to install a third-rail system. The heavy combination of Z-bars which formed the overhead conductor will be removed and current for the electric locomotives will be supplied by a rail running outside the wheel rails. This rail is to be of the standard A. S. C. E. section and weigh 75 lbs. per yard. Four miles of double track will be equipped, extending from the northern to the southern side of the city of Baltimore.

According to the proposed plan, in the stations and at some of the crossings where special precautions are desirable the rail is sectionalized electrically. The Murphy safety third-rail system is here used. To minimize the danger of shocks to the workmen and others who may have occasion to use the tracks, the rail is paralleled on each side by a pine plank set on edge. There is a few inches clearance between these guards and the rail, and the top edge of the plank extends a little above the head of the rail.

The insulators consist of blocks of reconstructed granite. These have vertical recesses to receive a pin on a malleable iron casting, which forms the base and extends laterally far enough to support the guard planks. A chair on which the rail rests is leaded on the top of the granite block and completes the insulator.

Transportation Figures at Paris Exposition

The work done by the moving sidewalk and the third-rail road at the Paris Exposition has been very gratifying to the management and to the authorities. It appears that from April 15 to May 13, inclusive, the two systems carried no fewer than 799,479 paying passengers, of whom by far the larger number traveled on the sidewalk, although the trip costs 10 cents while the third-rail fare is but 5 cents. In the period named, one day was lost, April 21, owing to an accident on the transmission cables, and there was a little delay once or twice on the sidewalk due, for example, to the swelling and binding of some of the moving wooden platforms after the heavy rains; but in all other respects both the walk and the road carried their patrons with comfort, regularity and safety.

The greatest number of passengers carried in one day was 75,000, on May 13, when there were slightly over 300,000 people at the show and when the time of operation was ten hours. On Easter Day they carried 61,000 passengers. The travel increases with the growth of the crowds at the Exposition, and it would seem that it is safe to count on handling 25 per cent of all the visitors, for even those who have once ridden for pleasure come back again and again to bring friends and to reach different parts of the grounds quickly. Indeed it is stated by observers that the regular attendants at the Exposition, in care of exhibits, etc., are the best customers, using the services as part of their daily means of transit. We are indebted to M. Maréchal, manager of the two systems, and to Charles Leblanc, general manager of the Compagnie Generale de Traction, which is interested in the enterprises, for the above data. It may be added that the Westinghouse sub-station receiving the current from the transmission line from Issy les Moulineaux, as described already, is in most satisfactory operation, and that the duplicate plants in it have been practically completed. Tests have been made as to the current used, and will be repeated from time to time. The data from the sidewalk would show it to be quite economical of current, with little increase as the load of travel is augmented.

Double-Current Generators for Electric Railway Service

The Massachusetts Electric Companies, which have consolidated thirty-eight railroads and two lighting systems in eastern Massachusetts, propose to reduce the cost of operation of their extensive system by centralizing their generating stations. The first move in this direction will be on that part of their system in and around Salem, and will be made by the addition of polyphase apparatus to transmit power from the present Salem direct-current station to neighboring towns. Sub-stations will be located in Wakefield, Essex and Gloucester.

Two 800-kw double-current generators will be installed at Salem, direct coupled to engines, making probably the first case of direct-coupled double-current machines for railway service in this country. These machines may be run in parallel with the three 300-kw direct-current machines now in service at this point, although there is some doubt as to the advisability of so running them on account of the disturbing effects of wattless currents on the field strength of the double-current machines. Since this disturbing effect will not be felt on the direct-current machines, it may affect the division of the direct-current load between the two classes of machines. If this is so to a serious extent, it may be necessary to run the double-current machines on a separate set of busses and a separate load from the direct-current machines.

The Massachusetts Electric Companies own the Lowell & Suburban road with its pioneer polyphase transmission line from Lowell to Nashua. The new transmission will be carried out in the same manner to a large extent.

Street Car Building

(Stephenson Practice.)

BY CHARLES HENRY DAVIS, C. E.

VI.—Assembling—(Continued)

In the June issue of the STREET RAILWAY JOURNAL we gave the details of the bottoms for our two standard cars; namely, the Boston (closed) and the Brooklyn (open). Tables Nos. 33 and 34 give respectively the details of bodies for these standard cars, while Plates V. and VI. illustrate the various parts. As in Tables 31 and 32, each distinct part of the body is described, giving the material, the general dimensions, how made, on what tools and how assembled, all in consecutive order as each car is built in the shop. In using these tables they are to be read across the page line by line as in the case of any book. In column 1 the numerals indicate, in consecutive order, the number of distinctive pieces; where a letter follows the numeral it indicates another operation, but not another distinctive piece. Letters in column 4 are the same abbreviations of timbers as used on Plates I. and II. These tables are given on the following seven pages.

The Toledo Traction Company has just issued a time table for the running of its cars, in the form of a little folder, which contains also some particulars of the city, as well as a handsomely lithographed bird's eye view of Toledo, in which the routes of the company's system are shown. In this map the site of the Ohio Centennial and Northwestern Territory Exposition in 1902 is clearly shown.

TABLE NO. 33

DETAIL OF SIDES AND ENDS (BODY) OF BOSTON CLOSED CAR, IN THE ORDER OF ASSEMBLING

(25 ft. Body; Car No. 2; Fig. 3; Plates I. and V.)

Consecutive Number	Quantity	Name of Piece	Piece Number Plates I. and V.	Material See Plates I. and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate V.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
33	8	**Side-posts** (Figs. 80, 81)	1002	A.	--	----------	--	5 ft. 11⅛ in. x 5 in. x 1⅝ in.	Are now (*see Table No. 31 and Plate II.*) laid on one side of the car flooring opposite their respective positions; each one is previously prepared as follows:—	
					1	Gain	a	3½ x 1¼ in. x ¾ in.	For side belt-rail (1015), Figs. 94, 95	Car gainer
					1	Gain	b	3 in. x 2 in.	For side rib-rail (1017), Figs. 99, 100	Car gainer
					1	Tenon	c	1⅝ in. x 1¼ in.	To tenon into mortise of side-sill, with hole for dowel-pin	Car gainer
					1	Tenon	d	1½ in. x 1 in.	To tenon into mortise of side top-rail (1005), Fig. 93	Car gainer
					2	Rabbets	e		For the window-sash to slide in, leaving a bead (g) on the outside, called the outside window-stop (1034). There are also	Routing machine
34	16	**Post parting-strips** (Fig. 90)	1035	C.	--	----------	--	2 ft. 10 in. x 1¼ x ⅝ x ¼ in.	Shown at (f) Figs. 80, 81, screwed to side-posts; they are temporarily attached merely to indicate their position, and when the sashes are fitted later they are secured with 64 No. 7 x ⅞ in. bronze screws	
35	16	**Sash parting-strips** (Not Ill.)	1037		--	----------	--	2 ft. 3 in. x ¼ in. x ¼ in.	Nailed to the posts along the rabbet (f) from below the belt-rail to the floor, to guide the sash when it is lowered; they are clearly seen in Fig. 75	
36	1	**Side belt-rail** (Figs. 94, 95)	1015	A.	--	----------	--	24 ft. 7¾ in. x 4 in. x 1¾ in.	Is now fitted to above side-posts, the gains (a) of the posts interlocking with the	
					8	Gains	a	1⅝ in. wide	Of the belt-rail; and, being further secured by small wooden wedges, are also screwed through	Multiple gainer
					16	Holes	b		With 8 No. 14 x 2 in. and 8 No. 14 x 3 in. steel screws to side-posts	Borer or multiple spindle drill
					1	Rabbet	c	1¾ in. x ½ in.	Runs the whole length of the belt-rail to receive the convex-panel	Molding machine
					1	Rabbet	d	½ in. x 1 in.	The whole length of the rail, for the window-sashes to rest on	Molding machine
					2	Tenons	--	3½ in. x 2½ in.	To fit into mortises (a) in corner-posts (1001), Figs. 76 to 79	End tenoner
					27	Mortises	--	1½ in. x ⅝ in. x 5-16 in.	On under side of rail for convex-panel ribs (1021), Fig. 86, to tenon into. For securing belt-rails to corner-posts, *see Con. No. 56 c*	Hollow chisel mortiser
37	2	**Side-post strap-bolts** (Fig. 124)	1501	W. I.	--	----------	--	9⅜ in. x ½ in.	Are now screwed to side-posts with 16 lag screws 1⅝ in. x ¼ in., after which the side-posts are erected upon one of the side-sills, the tenons being well white-leaded before being driven into their respective mortises, the strap-bolts well tightened up and the side-posts draw-pinned	
	6	**Side-post strap-bolts** (Fig. 125)	1501	W. I.	--	----------	--	9 9-16 x ½ in.		
37a	8	**Side-posts**	1002	A.	--	----------	--		The other side consisting as above of:—	
37b	16	**Post parting-strips**	1035	C.	--	----------	--			
37c	16	**Sash parting-strips**	1037		--	----------	--			
37d	1	**Side belt-rail**	1015	A.	--	----------	--			
37e	8	**Side-post strap-bolts**	1501	W. I.	--	----------	--		Is now put together and similarly erected, after which:—	
38	2	**Side rib-rails** (Figs. 99, 100)	1017	A.	--	----------	--	24 ft. 7¾ in. x 3½ x 2⅜ in.	Are screwed to the side posts, and secured with 16 No. 14 x 2 in. and 16 No. 14 x 3 in. steel screws. Each one has:—	
					8	Gains	a	1⅝ in. x 3-16 in.	To interlock with corresponding gains (b) of the side-posts	Multiple gainer
					2	Gains	a_1	2¾ in. x 3-16 in.	To interlock with corresponding rabbets (b) of the corner-posts (1001)	End tenoner
					27	Gains	b	1½ in. x 2½ in. x ⅜ in.	To receive the concave-panel ribs (1022), Fig. 87	Multiple gainer
					1	Rabbet	c	1 in. x ½ in.	To receive the convex-panel (1027)	Molding machine
					27	Rabbets	d	1½ in. x ⅝ in. x ½ in.	To receive the convex-panel ribs (1021), Fig. 86	Hollow chisel mortiser
					36	Holes	e		For screws to secure side fender-rail (1019), Fig. 101, to side rib-rail	Borer or multiple spindle drill
					4	Holes	f		For screws to secure the side rib-rail to corner posts	Borer or multiple spindle drill
					16	Holes	g		For screws to secure the side rib-rail to side posts as above	Borer or multiple spindle drill
					1	Rabbet	h	2¼ in. x ⅜ in.	To receive the concave-panel (1028), Fig. 113	Molding machine
									For securing side rib-rails to corner-posts. (*See Con. No. 56 d*)	
39	42	**Convex-panel ribs** (Fig. 86)	1021	A.	--	----------	--	17¼ in. x 1½ in. x ¾ in.	Each one having:—	Shaper
					1	Tenon	a	1½ in. x ½ in. x 5-16 in.	To fit into mortises on under side of side belt-rail	Double end tenoner and gainer
					1	Tenon	b	1½ in. x ⅝ in. x ½ in.	To fit into rabbets (d) of side rib-rail, to which they are screwed with 42 No. 12 x 1 in. steel screws. There are altogether 54 side panel-ribs, but the three next to each corner-post are put in later. (*See Con. No. 57 a*)	Double end tenoner and gainer
40	42	**Concave-panel ribs** (Fig. 87)	1022	A.	--	----------	--	10 in. x 1½ in. x ¾ in.	Each with:—	Shaper
					1	Tenon	a	1½ in. x ⅜ in.	To fit in mortises (d) of side-sills (Fig. 32, Plate IV.)	End tenoner
					1	Hole	b		For No. 14 x 2 in. screws to secure the ribs to the rib-rails. There are also 54 of these ribs, but the three next each corner-post are put in later. (*See Con. No. 57 b*)	Borer
41	4	**Convex-panel cleats** (Not Ill.)	1024	A.	--	----------	--	16 in. x 1½ in. x 1 in.	Glued and screwed with 16 No. 12 x 1¾ in. screws to the sixth side-post on opposite ends of the body (2 on each post) for securing the convex-panel splices	Shaper and borer
42	4	**Concave-panel cleats** (Fig. 88)	1025	A.	--	----------	--	10 in. x ¾ in. x 1 in.	Glued and screwed with 16 No. 12 x 1¾ in. screws to the sixth side-post on opposite ends of the body (2 on each post) for securing the concave-panel splices.	Shaper and borer
43	2	**Corner-posts** (Figs. 77, 78)	1001a	A.	--	----------	--	6 ft. 1⅞ in. x 8⅞ x 5 x 4 in.	And	
43a	2	**Corner-posts** (Figs. 76, 79)	1001b	A.	--	----------	--	6 ft. 1⅞ in. x 8⅞ x 5 x 4 in.	Are now set in the side-sill mortises (j), Fig. 33, Plate IV., but not fastened until later. (*See Con. No. 56 b*). Each one is previously prepared as follows:—	
					1	Mortise	a	3½ in. x 2½ in.	To receive tenon of side belt-rail (1015)	Hollow chisel mortiser
					1	Rabbet	b	3 in. x 2 in.	To interlock with gain (a_1) of side rib-rail (1017), Figs. 99, 100	Car gainer
					1	Tenon	c	3½ in. x 1¼ in.	To fit into mortise (j) of the side-sill	Double end tenoner and gainer

					1	Gain	d	2½ in. x 1 in.	To receive the end of the side top-rail (1005), Fig. 93	Double end tenoner and gainer
					1	Gain	e	4¼ in. x ½ in.	To receive the end of the letter-board (1010), Figs. 96, 97	Double end tenoner and gainer
					1	Rabbet	f	5-16 in. deep	For the window-sash to slide in	Routing machine
					1	Mortise	g	3¾ in. x 1¼ in. x ½ in.	To receive the tenon of the end belt-rail (1016), Fig. 120	Hollow chisel mortiser
					1	Mortise	h	2½ in. x 1¼ in. x ½ in.	To receive the tenon of the end rib-rail (1018), Fig. 121	Hollow chisel mortiser
					1	Rabbet	i	3¼ in. x ⅜ in.	To receive upper end-panel (1029)	Planer
					1	Mortise	j	1¾ in. x 9-16 in. x 1¼ in.	To receive nut of corner-post joint-bolt (1503), Fig. 128	Hollow chisel mortiser
					1	Mortise	k	2 in. x ⅜ in.	To receive tenon of end-lining top-rail (4023)	Hollow chisel mortiser
					2	Mortises	l	2¼ in. x ⅜ in.	To receive tenons of end-lining middle-rail (4024)	Hollow chisel mortiser
					1	Groove	m		To bury the trolley wire in	Routing machine
					1	Rabbet	n	4¼ in. x 2½ in. x ½ in.	To receive end window-lintel (1012), Fig. 118	Hollow chisel mortiser
					1	Rabbet	o	5-16 in. deep	From the top of the post to the belt-rail, to receive the end sash	Planer
					1	Mortise	p	1 in. x ⅜ in.	For sliding-door rear-track (4509)	Hollow chisel mortiser
					1	Gain	r	3⅜ in. x 1 in.	To receive the end of the end top-rail (1006), Figs. 108 to 111	End tenoner
					1	Rabbet	s	2 in. x ½ in.	To receive convex-panel (1027)	Shaper
									There are also :—	
44	4	**Post parting-strips** (Fig. 91)	1035	C.	--	----------	--		Shown at (t) Fig. 78, and	
45	2	**Inside window-stops** (Fig. 92)	1033	C.	--	----------	--		Shown at (u) Fig. 78, which are temporarily attached merely to indicate their position. With the bead along the outer edge of the post, called the outside window-stop (1034), they make two grooves, in one of which the window-sash slides, and in the other the window-shade. When the sashes are fitted later, they are secured with 26 No. 7 x ⅞ in. bronze screws	
46	2	**Door-posts (thick) on left hand** * (Figs. 82, 83)	1003	A.	--	----------	--	7 ft. 0⅞ in. x 3⅛ in. x 2½ in.	Are now set in the end-sill mortises (i), Fig. 36, Plate IV., but not fastened until later. (*See Con. No. 56 a*). Each one has been previously prepared as follows :—	
					1	Tenon	a	2½ in. x ½ in.	To fit into mortise of the end-sill, with two holes for dowel-pins	Double end tenoner and gainer
					1	Tenon	b	2½ in. x ½ in.	To fit into mortise of the end top-rail (1006), Fig. 108, with two holes for dowel-pins	Double end tenoner and gainer
					1	Mortise	c	3¼ in. x ½ in.	To receive tenon of end belt-rail (1016), Fig. 120	Hollow chisel mortiser
					1	Mortise	d	2½ in. x ½ in.	To receive tenon of end rib-rail (1018), Fig. 121	Hollow chisel mortiser
					1	Rabbet	e		To receive end of door-lintel (1011), Fig. 119	Hollow chisel mortiser
					1	Mortise	f		To receive tenon of door-lintel (1011), Fig. 119	Hollow chisel mortiser
					1	Rabbet	g	4¼ in. x ½ in.	To receive end window-lintel (1012), Fig. 118	Hollow chisel mortiser
					1	Rabbet	h	5-16 in. deep	For the stationary end window-sash to fit in	Planer
					1	Rabbet	i	⅜ in. deep	To receive the upper and lower end-panels (1029, 1030)	Planer
					1	Mortise	j	1 in. x ⅜ in.	For the end of the sliding-door top-rack (4508) to fit in	Hollow chisel mortiser
47	2	**Door-posts (thin) on right hand** (Figs. 84, 85)	1004	A.	--	----------	--	7 ft. 0⅞ in. x 2½ in. x 1¾ in.	Are now set in the end-sill mortises (j), Fig. 36, Plate IV., but not fastened until later. (*See Con. No. 56 a*). Each one has been previously prepared as follows :—	
					1	Tenon	a	2½ in. x ½ in.	To fit into mortise of the end-sill, with two holes for dowel pins	Double end tenoner and gainer
					1	Tenon	b	2½ in. x ½ in.	To fit into mortise of the end top-rail (1006), Fig 108, with two holes for dowel-pins	Double end tenoner and gainer
					1	Mortise	c	3¼ in. x ½ in.	To receive tenon of end belt-rail (1016), Fig. 120	Hollow chisel mortiser
					1	Mortise	d	2½ in. x ½ in.	To receive tenon of end rib-rail (1018), Fig. 121	Hollow chisel mortiser
					1	Rabbet	--		Not shown, to receive end of door-lintel, corresponding to (e) Fig. 83	Hollow chisel mortiser
					1	Mortise	--		Not shown, to receive tenon of door-lintel, corresponding to (f) Fig. 83	Hollow chisel mortiser
					1	Rabbet	e	4¼ in. x ½ in.	To receive end window-lintel (1012), Fig. 118	Hollow chisel mortiser
					1	Rabbet	f	5-16 in. deep	For the stationary end window-sash to fit in	Planer
					1	Rabbet	g	⅜ in. deep	To receive the upper and lower end-panels (1029, 1030)	Planer
					1	Rabbet	i	1 in. x ⅜ in.	For the end of the sliding-door rear-track (4509) to fit in	Hollow chisel mortiser
					1	Rabbet	j	1 in. x ⅜ in.	For the end of the sliding-door rear-sheave guide (4515) to fit in	Hollow chisel mortiser
					1	Pocket	k		To clear sliding-door rear-sheave (4513)	Borer
									There are also :—	
48	2	**Inside window-stops** (Fig. 89)	1033	C.	--	----------	--		Also shown at (h) Fig. 84, which are temporarily attached to show their position. When the sashes are later fitted, the window-stops are finally secured with 8 No. 7 x ⅞ in. bronze screws	
49	4	**End belt-rails** (Fig. 120)	1016	A.	--	----------	--	2 ft. 1⅝ in. x 3⅞ in. x 1¾ in.	Each having :—	
					1	Tenon	a	3¼ in. x 1¼ in.	Tenoned into corner-post mortise (g), Fig. 79	Double end tenoner and gainer
					1	Tenon	b	3¼ in. x 1¼ in.	Tenoned into door-post mortise (c), Figs. 82, 85	Double end tenoner and gainer
					1	Rabbet	c	⅜ in. deep	To receive the upper end-panel (1029)	Planer
					1	Rabbet	d	1 in. x ½ in.	For the window-sash to rest on when closed	Planer
					3	Rabbets	e	2 in. x 1½ in. x ½ in.	To interlock with the body end-ribs (1023), Fig. 131 ; these rails are firmly secured and pinned later, when the whole body framework is thoroughly squared. (*See Con. No. 55 a*)	Hollow chisel mortiser
50	4	**End rib-rails** (Fig. 121)	1018	A.	--	----------	--	2 ft. 1⅛ in. x 2 in. x 1¼ in.	Each having :—	
					1	Tenon	a	2½ in. x 1¼ in.	Tenoned into corner-post mortise (h), Fig. 79	Double end tenoner and gainer
					1	Tenon	b	2½ in. x 1¼ in.	Tenoned into door-post mortise (d), Figs. 82, 85	Double end tenoner and gainer
					3	Gains	c	2 in. x ½ in.	To interlock with the body end-ribs (1023), Fig. 131 ; these rails are pinned later. (*See Con. No. 55 b*)	Double end tenoner and gainer
51	2	**Door-lintels** (Fig. 119)	1011	A.	--	----------	--	2 ft. 5 in. x 5¾ in. x 1¾ in.	Each having :—	
					1	Tenon	a		Tenoned into door-post mortises (f), Fig. 83, and gained with door-post rabbet (e), Fig. 83	Double end tenoner and gainer
					1	Tenon	b		Tenoned into door-post mortises, and gained with door-post rabbets of thin door-posts, Figs. 84, 85, not shown, but corresponding to those of Figs. 82, 83. These are each pinned to the door-posts with four hickory dowel-pins	Double end tenoner and gainer
52	4	**End window-lintels** (Fig. 118)	1012	A.	--	----------	--	2 ft. 5 in. x 4¼ in. x ½ in.	Fitted to corner-post rabbets (n), Fig. 79, thick door-post rabbets (g), Fig. 83, and thin door-post rabbets (e), Fig. 84, to all of which they are screwed with 20 No. 12 x 1¼ in. steel screws	
53	2	**End top-rails** (Figs. 108 to 111)	1006	A.	--	----------	--	7 ft. 2 in. x 5½ in. x 1⅛ in.	In two pieces, spliced, and screwed together with 16 No. 14 x 1½ in. steel screws ; each one has :—	
					2	Gains	a	3⅜ in. x ¾ in.	Interlocked with corner-post gain (r), Figs. 77, 79, and secured with 12 No. 14 x 3 in. steel screws	Double end tenoner and gainer
					2	Gains	b		To receive the ventilator plain-bottom-rail (2002)	Car gainer
					2	Rabbets	c	2 in. x 1¼ in. x ⅝ in.	For ventilator end-corner-post (2004) shown in Fig. 107	Hollow chisel mortiser
					2	Mortises	d	2½ in. x ½ in.	To receive tenons (b) of door-posts, Figs. 82 to 85, which are draw-pinned	Hollow chisel mortiser

*In speaking of "right hand" and "left hand," the reader is supposed to be in the center of the car, and in this case looking toward the door. It will then be seen that, contrary to usual custom, the door, when being opened, slides to the right.

TABLE NO. 33—*Continued*

Consecutive Number	Quantity	Name of Piece	Piece Number Plates I. and V.	Material See Plates I and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate V.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
					4	Holes	e	⅝ in. diam.	For trolley wires to pass through	Borer or multiple spindle drill
					1	Rabbet	f	¼ in. x ⅝ in.	For ventilator end-sash (4007) to rest on	Shaper
									There are also screwed to the end top-rails :—	
54	14	**Furring-pieces** (Fig. 114 to 116)	1038	A.			-		Of various shapes and sizes, also seen in place in Fig. 111, secured with 32 No. 14 x 1½ in. to 3½ in. steel screws. These are to fasten the inside door-head lining to	
55	2	**Side top-rails** (Fig. 93)	1005	V. P.				25 ft. 0 in. x 3½ in. x 3¼ in.	Are now adjusted to the side-posts, the tenons of the latter entering the mortises on the underside of the rails. They are secured later. (*See Con. No. 58 a*). Each rail has :—	
					27	Gains	a	1⅛ in. x 1¼ in.	For the lower deck rafters to fit in	Double end tenoner and gainer
					1	Rabbet	b	⅝ in. x ½ in.	To receive the letter board (1010), Figs. 96, 97	Molding machine
					8	Gains (not marked in ill.)	c	⅛ in. x 1¼ in.	For the lower deck compound carlins to fit in	
									The body framework is now squared, after which several of the previous operations are completed, as follows :—	
55a	--	**End belt-rails**	1016	----	--	...	--		Are secured to corner and door-posts with 8 hickory dowel-pins (*See Con. No. 49*)	
55b	--	**End rib-rails**	1018	----	--	...	--		Are secured to corner and door-posts with 12 hickory dowel-pins. (*See Con. No. 50*)	
56	4	**Door-post strap-bolts** (Fig. 126)	1504	W. I.	--	...	-	12⅝ in. x ⅝ in.	Fastened to door-posts with 8 lag screws 1⅝ in. x ½ in., after which the four	
56a	--	**Door-posts**	1003,4	----	--	...	--		(*Con. Nos. 46, 47*) are bolted to end-sills with above strap-bolts, and pinned with 8 hickory dowel-pins	
56b	--	**Corner-posts**	1001a,b	----	--	...	--		(*Con. Nos. 43, 45*) are now pinned to side-sills with 8 hickory dowel-pins. (*See Con. No. 80* for completion)	
56c	--	**Side belt-rails**	1015	----	--	...	--		(*Con. No. 39*) are now secured to corner-posts with 4 No. 14 x 3 in. and 4 No. 14 x 2 in. steel screws	
56d	--	**Side rib-rails**	1017	----	--	...	--		(*Con. No. 38*) are now secured to corner-posts with 4 No. 14 x 3 in. and 4 No. 14 x 2 in. steel screws. Work then proceeds as follows :—	
57	8	**Body end-ribs** (Fig. 131)	1023	A.	-	...	--	2 ft. 10¼ in. x 1½ in. x ⅞ in.	And	
	4	**Body end-ribs** (Fig. 131)	1023	A.	--	...	-	2 ft. 6⅛ in. x 1½ in. x ⅞ in.	Each having :—	
					1	Gain	a	2 in. x ⅜ in.	To fit into rabbets (e) of end belt-rails (1016), Fig. 120	Car gainer
					1	Gain	b	2 in. x ⅜ in.	To interlock with gain (c) of end rib-rails (1018), Fig. 121	Car gainer
					1	Gain	c	1½ in. x ⅜ in.	To interlock with rabbet (h) of end sills (2), Fig. 36. The gain (c) of the four shorter ribs interlocks with rabbet (n) of side-sills (1), Fig. 33. The ribs are secured with 36 No. 12 x 1 in. steel screws	Car gainer
57a	12	**Convex-panel ribs** (Fig. 86)	1021	A.	--	...	--	17¼ in. x 1½ in. x ¾ in.	Fitted same as the 42 ribs, *Con. No. 39*, these being the three next to each corner-post, and secured with 12 No. 12 x 1 in. steel screws	
57b	12	**Concave-panel ribs** (Fig. 87)	1022	A.	--	...	--	10 in. x 1½ in. x ¾ in.	Fitted same as the 42 ribs, *Con. No. 40*, these being the three next to each corner-post, and secured with 12 No. 14 x 2 in. steel screws	
58	4	**Side-braces** (Fig. 129)	1026	A.	--	...	--	2 ft. 11¼ in. x 2½ x 1¾ in.	Each with :—	
					3	Gains	a	1½ in. x ¾ in.	For convex-panel ribs; screwed to corner-posts with 4 No. 20 x 5 in. screws to side rib-rails with 4 No. 20 x 4 in. screws, and to convex-panel ribs with 12 No. 12 x 1¼ in. steel screws	Car gainer
58a	--	**Side top-rails**	1005	----	--	...	--		(*Con. No. 55*) are now pinned to side-posts, and fitted and screwed to corner-posts with 8 No. 14 x 3 in. steel screws	
59	2	**Concave-panels** (Fig. 113)	1028	P.	--	...	--	25 ft. 0 in. x 17⅜ in. x ⅜ in.	The body at this stage is accurately represented by Fig. 75 In two pieces, spliced, the splicing being made at the side-posts with the panel-cleats (1025) (*See Con No 42*). The panels, after being bent on a former and dried, are glued, white-leaded, and nailed to the corner and side-posts, the rib-rails, side-sills and panel-ribs	
60	72	**Side-sill watersheds** (Not Ill.)	1052	P.	--	...	--	6⅝ in. x ¾ in. x ¾ in.	Glued to panels and side-sills between all the panel-ribs	
61	--	**Linen scrim**	----	----	--	...	--		Is now glued to the concave panels, lapping on to ribs, posts, rails and side-sills	
62	2	**Convex-panels** (Fig. 107)	1027	P.	--	...	--	24 ft. 8 in. x 18½ in. x 1½ in.	In two pieces, spliced same as the concave-panels. They are also glued, white leaded and nailed to the corner and side-posts, the belt and rib-rails and the panel-ribs. They are also screwed to corner and side-posts with 100 No. 10 x 1¼ in. steel screws	
63	72	**Rib-rail watersheds** (Not Ill.)	1051	P.	--	...	--	6⅝ in. x 11-16 in. x 11-16 in.	Glued to panels and rib-rails between all the panel-ribs	
64	--	**Linen scrim**	----	----	--	...	--		Is now glued to the convex-panels, lapping onto ribs, posts and rails	
65	4	**Lower end-panels** (Fig. 107)	1030	P.	--	...	--	1 ft. 9 in. x 2 ft. 4½ in. x ⅜ in.	Glued, white-leaded and nailed to the corner and door-posts, the end rib-rails, end-sills and end-ribs	
66	4	**Upper end-panels** (Fig. 107)	1029	P.	--	...	--	2 ft. 2 in. x 1 ft. 7 in. x ⅜ in.	Glued, white-leaded and nailed to the corner and door-posts, the end belt and rib-rails, and the panel ribs. They are also screwed to the corner-posts with 20 No. 10 x 1¼ in. screws	
67	--	**Linen scrim**	----	----	--	...	--		Is now glued to the end-panels, lapping onto posts, rails, end-sills and ribs	
68	8	**Furring-pieces** (Fig. 117)	1038	A.	--	...	--		Of various shapes and sizes, as shown, screwed to end top-rail (1006) with 20 No. 14 steel screws; they are used in connection with the wiring	
69	2	**Furring-pieces** (Fig. 138)	1038	A.	--	...	--		For sliding-door top-track (4508), screwed to end top-rail	
70	2	**Furring-pieces** (Fig. 139)	1038	A.	--	...	--		For sliding door rear-track (4509), screwed to end top-valance (1013)	
71	2	**End top-valances** (Fig. 112)	1013	P.	--	...	--	⅜ in. thick	Glued and nailed to end top-rail, side and door-posts and end window-lintels	
72	2	**Letter-boards** (Figs. 96, 97)	1010	A.	--	...	--	25 ft. 0¾ in. x 7 in. x 1 in.	Screwed through	
					90	Holes	a		To side top-rails with No. 12 x 1½ in. steel screws, and through	Borer or multiple spindle drill

					60	Holes	b		To corner and side-posts with No. 12 x 1½ in. steel screws. There are also in each one :	Borer or multiple spindle drill
					45	Holes	c		For screws to secure the drip-rails (1014). *See Con. No. 75*	Borer or multiple spindle drill
73	2	**Side fender-rails** (Fig. 101)	1019	A.	..	----------	..	25 ft. 2½ in. x 3 in. x 1⅞ in.	Screwed to side rib-rails through holes (e), Figs. 99, 100, with 72 No. 14 x 3 in. steel screws	
74	4	**End fender-rails** (Fig. 122)	1020	A.	..	----------	..	2 ft. 6½ in. x 1¼ in. x 1¼ in.	Screwed to end rib-rails (Fig. 121) with 24 No. 14 x 1½ in. to 2½ in. steel screws	
75	2	**Drip-rails** (Fig. 98)	1014	A.	..	----------	..	24 ft. 9 in. x 1¾ in. x ⅞ in.	Screwed through (c) Fig. 97 to letter-boards with 90 No. 12 x 2 in. steel screws	
76	4	**Corner-post angle-plates** (Fig. 127)	1511	W. I.	..	----------	..		Screwed to corner posts and top end-rails with 16 No. 16 x 2½ in. steel screws	
77	2	**Belt-rail bands** (Not Ill.)	1505	W. I.	..	----------	..	⅞ in half-round	Screwed to side and end belt-rails with 152 No. 12 x 1½ in. steel screws	
78	2	**Fender-guards** (Not Ill.)	1506	W. I.	..	----------	..	⅞ in. half-round	Screwed to side and end fender-rails with 152 No. 12 x 1½ in. steel screws	
79	20	**Convex-panel iron-straps** (Fig. 141)	1507	W. I.	..	----------	..	1¼ in. x 3-32 in.	Screwed through convex-panels at each corner and side-post, between belt and fender-rails, with 160 No. 10 x 1¼ in. steel screws ; these and the following straps are all leaded before putting on	
80	20	**Concave-panel iron-straps** (Fig. 142)	1508	W. I.	..	----------	..	1¼ in. x 3-32 in.	Screwed through the concave-panels at each corner and side-post, from fender-rail to bottom of the panel, with 160 No. 10 x 1¼ in. steel screws	
81	4	**Upper end-panel iron-straps** (Fig. 143)	1509	W. I.	..	----------	.	1 in. x 3-32 in.	Screwed to corner posts over the edges of the upper end panels with 32 No. 10 x 1¼ in. steel screws	
82	4	**Lower end-panel iron-straps** (Fig. 144)	1510	W. I.	..	----------	..	1¼ in. x 3-32 in.	Screwed to door-posts over the edges of the lower end-panels with 36 No. 10 x 1¼ in. steel screws	
83	8	**Corner-post ½ round-moldings** (Not Ill.)	1031	P.	..	----------	..	1½ in. wide	Nailed to sides and ends of corner-posts, from belt-rail to end top-valance	
84	4	**Door-post ½ round-moldings** (Not Ill.)	1032	P.	..	----------	..	1½ in. wide	Nailed to door-posts from end top-valance to fender-rail	
85	4	**Platform step-hanger brackets** (Fig. 123)	1512	C. I.	..	----------	..		Screwed to corner posts, side and end-sills with 44 No. 18 x 1¾ in. steel screws. They are also further secured by 4 bolts in holes (a), 6¼ in. x ½ in., countersunk heads, which pass through the end-sills and overhang truss-rod anchor-irons. (*See Con. No. 24, Table 31*)	
86	4	**Corner-post joint-bolts** (Fig. 128)	1503	W. I.	..	----------	..	17 in. x ½ in.	Are now inserted through a hole in underside of platform step-hanger bracket, through end sill hole (c), Fig. 36, Plate IV., through side-sill hole (k), Figs. 32, 33, Plate IV., and into the corner-post, being then secured by the nut inserted in the hole (j) in the corner-post (Fig. 79). This completes *Con. No. 50 b*	
87	36	**Sash-rests** (Not Ill.)	1053	A.	..	----------	..	6 in. x ¾ in. x ¾ in.	Nailed to the bottom of the side-sills for the window-sashes to rest on when lowered	
88	2	**Overhang truss rod queen-posts** (Fig. 32, Plate IV.)	516	C. I.	..	----------	..	7 in. x 7¼ in. x 1¾ in.	Screwed to side-sills and secured with 8 lag screws, 2½ in. x ½ in. (*See Con. No. 24, Table 31*)	
89	2	**Truss-rods** (Not Ill.)	515	W. I.	..	----------	..	1 in. diam.	In two pieces, joined together with :—	
90	2	**Overhang truss-rod turn-buckles** (Fig. 32, Plate IV.)	518	M. I.	..	----------	..	9 in. x 2¼ in. x 2 in.	The ends of the rods being passed through the anchor-irons (517) (*see Con. No. 24, Table 31*) and secured with nuts, are then passed over the queen posts and joined together with the turn-buckles, which are screwed up tight	
91	4	**Seat-rail cleats** (Fig. 132)	1056	A.	..	----------	..	23¾ in. x 1¼ in. x ⅞ in.	Screwed to corner posts with 20 No. 10 x 2½ in. steel screws ; a shoulder at the bottom serves to support the back seat-supporting-rail (1054), Fig. 102	
92	2	**Back seat-supporting-rails** (Fig. 102)	1054	A.	..	----------	..	24 ft. 5¾" x 3¼" x 1½" & ⅝"	Screwed to side-posts and seat-rail cleats with 20 No. 14 x 1½ in. and 20 No. 14 x 2½ in. screws. Each rail has :—	
					1	Shoulder	a	1¾ in. x ⅞ in.	Its whole length to support the seat-lids (1060), Fig. 136	Molding machine
					8	Rabbets	b	1½ in. x ⅞ in. x ½ in.	To receive the seat-bearing cross-bars (1059), Fig. 137	Hollow chisel mortiser
93	2	**Lock-rails** (Fig. 103)	1055	A.	..	----------	..	24 ft. 5¾ in. x 4¼ in. x ⅞ in.	Each having :—	
					8	Gains	a	4¼ in. x 1⅝ in. x ¾ in.	To fit side-posts and seat-rail cleats to which they are screwed with 40 No. 14 x 1½ in. steel screws	Car gainer
94	16	**Seat-legs** (Fig. 134)	1058	A.	..	----------	..	13⅞ in. x 1½ in. x ¾ in.	Each having :—	
					2	Round tenons	..		To fit into corresponding holes in the floor and the seat-bearing cross-bars (1059). They are now glued and driven into the holes in the flooring-boards, after which :—	End tenoner and lathe
95	16	**Seat-bearing cross-bars** (Fig. 137)	1059	A.	..	----------	..	15½ in. x 1½ in. x 1½ & ⅝ in.	Each having :—	
					1	Tenon	a	⅞ in. x ½ in.	Are fit into rabbets (a) of the back seat-supporting-rails (1054), and are then screwed to them with 32 No. 10 x 1½ in. screws	End tenoner
					1	Tenon	b	¾ in. x ½ in.	To fit into similar rabbets of the front seat supporting-rail (1057), Fig. 104	End tenoner
					1	Hole	c	¾ in. diam.	(Not seen), into which the top tenon of the seat-leg is driven, being well glued first	Horizontal borer
96	2	**Front seat-supporting-rails** (Figs. 104, 105)	1057	A.	..	----------	..	24 ft. 3⅞ in. x 2 in. x 1⅛ in.	Each having :—	
					8	Rabbets	a	1½ in. x ¾ in. x ½ in.	To receive the tenons (b) of the seat-bearing cross-bars (1059), to which they are screwed with 32 No. 10 x 1½ in. screws	Hollow chisel mortiser
					1	Rabbet	b	¾ in. x ½ in.	Running its whole length, to receive the seat-lids (1060), Fig. 136	Molding machine
					1	Bead	c	½ in. x ⅛ in.	Running its whole length, to secure the front seat-supporting-rail facia (4121)	Molding machine
97	18	**Seat-lids** (Fig. 136)	1060	A. & P.	..	----------	..	2 ft. 8¼ in. x 15 in. x ⅞ in.	Being composed of :—	
97a	54	**Seat-lid boards** (Not Ill.)	1062	P.	..	----------	..	10¾ in. x 15 in. x ⅞ in.	Joined together and screwed to	
98	36	**Seat-lid battens** (Not Ill.)	1061	A.	..	----------	..	2 ft. 6¾ in. x 2½ in. x ½ in.	With 216 No. 10 x ¾ in. steel screws	
99	4	**Mud-blocks** (Fig. 135)	1067	Y. P.	..	----------	..	6½ in. x 2½ in. x ½ in.	Screwed to the floor near the door-posts	
100	4	**Door stop-blocks** (Fig. 140)	1049	A.	..	----------	..		Screwed to corner-posts with 4 No. 14 x 2 in. screws	
101	2	**Plain advertising-rack rails** (Fig. 106)	1069	A.	..	----------	..	24 ft. 4 in. x 4¾ in. x ⅞ in.	Screwed through	
					32	Holes	a		To side-posts with No. 14 x 2 in. steel screws, and	Borer or multiple spindle drill
					54	Holes	b		To side top-rails with No. 14 x 2 in. steel screws. Each one has also	Borer or multiple spindle drill
					45	Holes	c		Through which the screws (c) (*Con. Nos. 72, 75*), can be got at without taking down the whole rail	Borer or multiple spindle drill
					1	Rabbet	d	½ in. x ⅛ in.	Running its whole length, for the lower-deck ceiling-panel (4075)	Molding machine
					1	Rabbet	e	½ in. x ¼ in.	Running its whole length, for wires to the electric-bell push-buttons (4538)	Molding machine
102	2	**Door-sill plates** (Fig. 146)	1513	C. I.	..	----------	..		Screwed to end-sills between door-posts, and secured with 22 No. 14 x 1 in. screws	
103	2	**Door guide-plates** (Fig. 145)	1514	C. I.	..	----------	..		Screwed to end-sills between corner-posts and thin door-posts (1004), and secured with 6 No. 14 x 1 in. steel screws	
									The body is now ready to receive the roof, for description of which see *Con. No. 104, Table No. 35 and Plate VII.*	

Number of Distinctive Pieces	71	(Column 1)
Total Number of Pieces	746	(" 2)
Number of Bolts	4	(" 6 and 10)
Number of Screws (about)	2150	(" 6 and 10)
Number of Nails	?	
Total	2900	

Note.—Pieces described under Con. Nos. 91 to 100 are not usually assembled at this stage, but as they cannot be classified with "Cabinet Work," they are brought in here. Reference will be made to them further on when describing other pieces or operations to which they are accessory.

TABLE NO. 34

DETAIL OF SIDES AND ENDS (BODY) OF BROOKLYN OPEN CAR, IN THE ORDER OF ASSEMBLING

(12 benches; Car No. 4; Fig. 5; Plates II. and VI.)

Consecutive Number	Quantity	Name of Piece	Piece Number Plates II. and VI.	Material See Plates I. and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate VI.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
									The assembling of the pieces composing the ends of an open car is proceeded with independently of the bottom (*see Table No. 32 and Plate II.*), and only when the end framework or end-bulkhead (6001) as it is termed, is completed, as shown in Fig. 147, is the building up of the car body as a whole proceeded with. The pieces of which the end-bulkheads are composed, and the manner in which they are assembled, are as follows, all joints being well glued:—	
28	4	**End center-posts** (Figs. 170, 171)	6005	A.			..	6 ft. 11⅝ in. x 3⅝ x 1¾ in.	Each having:—	
					1	Tenon	a	2¼ in. x 1⅛ in. x ⅞ in.	To tenon into mortise (b) of bottom false-sill (6011), Fig. 161	Double end tenoner and gainer
					1	Gain	b	5¼ in. x 1⅛ in. x ½ in.	For outside end-bottom-rail (6010), Fig. 160, to gain into	Double end tenoner and gainer
					1	Gain	c	5¼ in. x 1½ in. x ½ in.	For inside end-bottom-rail (6009), Fig. 159, to gain into	Double end tenoner and gainer
					1	Gain	d	2⅝ in. x 1½ in. x 13-16 in.	For outside end-belt-rail (6008), Fig. 158, to gain into	Double end tenoner and gainer
					1	Gain	e	2 13-16 in. x 1½ in. x ½ in.	For inside end-belt-rail (6007), Fig. 157, to gain into	Double end tenoner and gainer
					1	Gain	f	3½ in. x 1½ in. x ½ in.	For end sub-top-rail (6012), Fig. 162, to gain into	Double end tenoner and gainer
					1	Tenon	g	2⅜ in. x 1½ in. x ½ in.	To tenon into mortise (b) on underside of end top-rail (6006), Fig. 150	Double end tenoner and gainer
					2	Bolt-holes	h	⅜ in. diam.	For bolts to secure the end-post strap-bolts (6509), Fig. 191	Borer or multiple spindle drill
					2	Rabbets	i	5-16 in. deep	Running down the post from the gain (f) to the bottom, for the window-sashes to slide in, leaving beads (j) on the outside, called the outside window-stop. To complete the grooves in which the 6 end-sashes slide, there are in all:—	Planer
29	12	**Post parting-strips** (Fig. 175)	6024	A.			..	2 ft. 9 15-16 x ⅞ & ¾ x 5-16 in.	Also shown at (k), Fig. 171, screwed to the different end-posts with 60 No. 7 x ¾ in. bronze screws	
30	4	**False end-posts** (Figs. 172, 173)	6004	A.			..	6 ft. 5⅞ in. x 3⅝ in. x 1⅜ in.	Each having:—	
					1	Tenon	a	2 in. x 1⅛ in. x ⅞ in.	To tenon into mortise (d) of bottom false-sill (6011), Fig. 161	Double end tenoner and gainer
					1	Gain	b	5¼ in. x 1⅛ in. x ½ in.	For outside end-bottom-rail (6010), Fig. 160, to gain into	Double end tenoner and gainer
					1	Gain	c	5¼ in. x 1⅛ in. x ½ in.	For inside end-bottom-rail (6009), Fig. 159, to gain into	Double end tenoner and gainer
					1	Gain	d	2⅝ in. x 1⅛ in. x 13-16 in.	For outside end-belt-rail (6008), Fig. 158, to gain into	Double end tenoner and gainer
					1	Gain	e	2 13-16 in. x 1⅛ in. x ½ in.	For inside end-belt-rail (6007), Fig. 157, to gain into	Double end tenoner and gainer
					1	Gain	f	3½ in. x 1⅛ in. x ½ in.	For end sub-top rail (6012), Fig. 162, to gain into	Double end tenoner and gainer
					1	Tenon	g	2⅜ in. x 1⅛ in. x ½ in.	To tenon into mortise (c) on under side of end-top-rail (6006), Fig. 150	Double end tenoner and gainer
					1	Rabbet	h	5-16 in. deep	Running down the post from the gain (f) to the bottom, for the window-sash to slide in, leaving a bead (i) on the outside, called the outside window-stop. Post parting-strips (6024), Fig. 175, also shown at (j) are screwed to the posts to complete the grooves in which the end-sashes slide. (*See Con. No. 29*)	Planer
					1	Rabbet	..	2 ft. 8¾ in. x 1⅛ in. x 5-16 in.	Running from gain (f) to gain (d) on the other side of the post, for the bulkhead-panel (9043) to fit in	Planer
31	2	**End top-rails** (Figs. 150, 151, 152)	6006	A.			..	6 ft. 11¾ in. x 4⅛ in. x 1¾ in.	In two pieces, spliced, glued and screwed together with 16 No. 14 x 1½ in. steel screws, each one having:—	
					2	Tenon	a	3½ in. x 2⅜ in. x ⅞ in.	To fit into mortises (b) of corner-posts (6002), Figs. 148, 149	Double end tenoner
					2	Mortises	b	2⅜ in. x 1½ in. x ½ in.	On underside, to receive tenons (g) of end center-posts (6005) with ¼ in. holes for wood pins	Hollow chisel mortiser
					2	Mortises	c	2⅜ in. x 1⅛ in. x ½ in.	On underside, to receive tenons (g) of false end-posts (6004) with ¼ in. holes for wood pins	Hollow chisel mortiser
					1	Mortise	d	1½ in. x 2 in. x ½ in.	On upperside, to receive tenon of ventilator end-center-post (7006) with ¼ in. hole for wood pin	Hollow chisel mortiser
					2	Mortises	e	2 in. x 1⅞ in. x ½ in.	On upperside, to receive tenons of ventilator end-corner-posts (7004) with ¼ in. holes for wood pins	Hollow chisel mortiser
					2	Rabbets	f	2 3-16 in. x 1 in. x 3-16 in.	For end top-rail tie-plates (6504), Fig. 176	Hollow chisel mortiser
					2	Rabbets	g	1 ft. 8½ in. x ½ in. x 5-16 in	To receive the ventilator end-sign-sashes (9017)	Shaper
32	2	**Bottom false-sills** (Fig. 161)	6011	A.			..	6 ft. 2¼ in. x 3⅝ in. x 1¼ in.	Each having:—	
					2	Tenons	a	¾ in. x ¾ in. x 1¼ in.	To tenon into mortises (g) of the corner-posts (6002), Figs. 148, 149	Double end tenoner
					2	Mortises	b	1½ in. x ⅞ in. x 1¼ in.	To receive tenons (a) of end center-posts (6005) with ¼ in. holes for wood pins	Holllow chisel mortiser
					2	Bolt-holes	c	½ in. diam.	For end center-post strap-bolts (6509), Fig. 191	Borer or multiple spindle drill
					2	Mortises	d	1⅛ in. x ⅞ in. x 1¼ in.	To receive tenons (a) of false end-posts (6004)	Hollow chisel mortiser
									The tenons of the end-posts are inserted in their respective mortises in the end top-rail and bottom false-sill, and after being squared the end center-posts are draw-pinned	
33	2	**Inside end-belt-rails** (Fig. 157)	6007	A.			..	6 ft. 10½ in. x 2⅞ in. x ¾ in.	Each having:—	
					2	Tenons	a	1¾ in. x ⅜ in. x 2⅞ in.	One at each end (not seen in the figure) to fit into mortises (e) in corner-posts (6002)	Double end tenoner and gainer
					2	Gains	b	1½ in. x ¼ in. x 2⅞ in.	To interlock with gains (e) of the end center-posts (6005) to which they are screwed with 8 No. 12 x 1¼ in. bronze screws.	Double end tenoner and gainer
					2	Gains	c	1⅛ in. x ¼ in. x 2⅞ in.	To interlock with gains (e) of the false end-posts (6004) to which they are screwed with 8 No. 12 x ¼ in. bronze screws.	Double end tenoner and gainer
34	2	**Inside end-bottom-rails** (Fig. 159)	6009	A.			..	6 ft. 7⅜ in. x 5¼ in. x ¾ in.	Same as outside end-bottom-rails, Fig. 160, each having:—	
					2	Tenons	a	1¾ in. x ⅜ in. x 5¼ in.	One at each end, to fit into mortises (c) in corner-posts (6002)	Double end tenoner and gainer
					2	Gains	b	1½ in. x ¼ in. x 5¼ in.	To interlock with gains (c) of the end center-posts, to which they are screwed with 8 No. 12 x 1¼ in. bronze screws	Double end tenoner and gainer
					2	Gains	c	1⅛ in. x ¼ in. x 5¼ in.	To interlock with gains (c) of the false end-posts, to which they are screwed with 8 No. 12 x 1¼ in. bronze screws	Double end tenoner and gainer
35	2	**Outside end-belt-rails** (Fig. 158)	6008	A.			..	6 ft. 10½ in. x 2⅞ in. x 1⅛ in.	Each having:—	
					2	Tenons	a	1¾ in. x ½ in. x 2⅝ in.	To fit into mortises (d) in corner-posts (6002)	Double end tenoner and gainer
					2	Gains	b	⅞ in. x ¼ in. x 2⅝ in.	To interlock with gains (d) of the end center-posts, to which they are screwed with 8 No. 12 x 1¼ in bronze screws	Double end tenoner and gainer
					2	Gains	c	13-16 in. x ¼ in. x 2⅝ in.	To interlock with gains (a) of the false end-posts, to which they are screwed with 8 No. 12 x 1¼ in. bronze screws	Double end tenoner and gainer
					1	Rabbet	d	⅞ in. x ¼ in.	Full length for the window-sashes to rest on	Molding machine

ILLUSTRATING

STREET CAR BUILDING

(Stephenson Practice)

By

Charles Henry Davis, C. E.

36	2	**Outside end-bottom-rails** (Fig. 160)	6010	A.	--	----------	--	6 ft. 7⅜ in. x 5¼ in. x ¾ in.	Same as inside end-bottom-rails, Fig. 159, each having :—
					2	Tenons	a	1¾ in. x ⅜ in. x 5¼ in.	To fit into mortises (b) in corner-posts (6002) — Double end tenoner and gainer
					2	Gains	b	1½ in. x ¼ in. x 5¼ in.	To interlock with gains (b) of the end center-posts, to which they are screwed with 8 No. 12 x ¼ in. bronze screws — Double end tenoner and gainer
					2	Gains	c	1⅛ in. x ¼ in. x 5¼ in.	To interlock with gains (b) of the false end-posts, to which they are screwed with 8 No. 12 x 1¼ in. bronze screws — Double end tenoner and gainer
37	2	**End sub-top-rails** (Fig. 162)	6012	A.	--	----------	--	6 ft. 11½ in. x 3½ in. x ½ in.	Each one fitting in gains (f) of the end center-posts, and the gains (f) of the false end-posts, to which they are screwed with 16 No. 12 x 1¼ in. steel screws. They further fit in rabbets (f) of the corner-posts, to which they are also screwed with 8 No. 12 x 1¼ in. steel screws
									The inside portion of the end-bulkhead framework being put together as described, and thoroughly squared, it is completed by the addition of
38	4	**Corner-posts** (Figs. 148, 149)	6002	A.	--	----------	--	6 ft. 5 in. x 4 in. x 3⅝ in.	Each having :—
					1	Tenon	a	2¼ in. x ⅞ in. x 3⅝ in.	To fit into mortise (a) of the side-sill, Plate IV., Fig. 49 — End tenoner
					1	Mortise	b	5¼ in. x 1¾ in. x ⅜ in.	For tenon (a) of the outside end bottom-rail (6010) to fit into — Hollow chisel mortiser
					1	Mortise	c	5¼ in. x 1¾ in. x ⅜ in.	For tenon (a) of the inside end-bottom-rail (6009) to fit into — Hollow chisel mortiser
					1	Mortise	d	2⅝ in. x 1¾ in. x ½ in.	For tenon (a) of the outside end-belt-rail (6008) to fit into — Hollow chisel mortiser
					1	Mortise	e	2⅞ in. x 1¾ in. x ¾ in.	For tenon (a) of the inside end-belt-rail (6007) to fit into — Hollow chisel mortiser
					1	Rabbet	f	3½ in. x 2 in. x ½ in.	For ends of end sub-top-rail (6012) to fit in — Hollow chisel mortiser
					1	Mortise	g	1¼ in. x ¾ in. x ¾ in.	For tenon (a) of the bottom false-sill (6011) to fit into — Hollow chisel mortiser
					1	Mortise	h	3½ in. x 2⅜ in. x ⅞ in.	For tenon (a) of the end top rail (6006) to fit into — Hollow chisel mortiser
					1	Mortise	i	2⅝ in. x 2 in. x ⅞ in.	For tenon (a) of the side top-rail (6018), Fig. 163, to fit into — Hollow chisel mortiser
					1	Pocket	j	3½ in. diam.	For curtain edge to fit in when rolled up ; there is a counterbore 13-16 in. diam. in the center to receive the end of the curtain-roller and the roller-sockets. — Borer
					1	Groove	k	½ in. x ½ in.	For the curtain-guides to slide in — Routing machine
					1	Chamfer	l		To take away the sharp edge of the post — Shaper
					1	Rabbet	m	2 ft. 8¾ in. x ½ in. x 5-16 in.	For the bulkhead-panel (9043) to fit in — Planer
					1	Rabbet	n	6⅝ in. x 1⅞ in. x. ⅜ in.	For side sub-top-rail (6019) to fit in — Hollow chisel mortiser
					2	Bolt-holes	o	⅜ in. diam.	For bolts to secure corner-post strap-bolts (6507) — Borer or multiple spindle drill
					1	Pocket	--		(Not seen) at the top on the outside face of the post, similar to pocket (n) of the side-post, seen in Fig. 181, for guard-rail catch-finger (6515), Fig. 178, to fit in
									The tenons of the various end-rails are well glued, then inserted in their corresponding mortises in the corner-posts, and afterward draw-pinned with hickory dowel-pins. To further strengthen the bulkhead
39	4	**End top-rail tie-plates** (Fig. 176)	6504	S. I.	--	----------	--	4⅜ in. x 1 in. x 3-16 in.	Are inserted in rabbets (f) of the end top rail, and screwed to it and to the end center-posts with 16 No. 12 x 1 in. steel screws.
40	2	**End-valance arch pieces** (Fig. 153)	6013	P.	--	----------	--	5 ft. 9 in. x 3½ in. x ⅜ in.	Are now nailed to the end top-rails, end sub-top-rails, corner and end-posts ; how they are placed may be judged from the full view of the bulkhead as it now appears, Fig. 147, where the valance pieces make a kind of bead 5-16 in. wide round the three upper end openings of the bulkhead, to secure the glass for the bulkhead valance lights
	4	**End-valance corner pieces** (Fig. 154)	6013	P.	--	----------	--	9 ft. x 9⅞ in. x ⅜ in.	
	4	**End-valance upright pieces** (Fig. 155)	6013	P.	--	----------	--	11⅛ in. x 2⅛ in. x ⅜ in.	
	2	**End-valance bottom pieces** (Fig. 156)	6013	P.	--	----------	--	5 ft. 7¼ in. x 1½ in. x ⅜ in.	
									The end-bulkheads are now erected bodily on the car bottom, the corner-post tenons being driven into the side-sill mortises (a) Plate IV., Fig. 49, after being well white-leaded. The two bottom false-sills (6011) are then screwed to the flooring-boards with 6 No. 14 x 2 in steel screws, while further stability is secured by
41	4	**Corner-post strap-bolts** (Fig. 189)	6507	W. I.	--	----------	--	15⅝ in. x 9-16 in.	Bolted to the corner-posts through holes (o), Fig. 148, with 8 bolts 4¼ in. x 5-16 in., and inserted in holes (h) in the side-sills, Fig. 49, and tightened up with their nuts
42	4	**End-post strap-bolts** (Fig. 191)	6509	W. I.	--	----------	--	10½ in. x 9-16 in.	Bolted to the end center-posts, through holes (h), Fig 171, with 8 bolts 2⅛ in. x 5-16 in., and inserted in holes (c) of the bottom false-sills (Fig. 161) and the flooring-boards, and tightened up with their nuts
									The assembling of the pieces composing the body now proceeds as follows :—
43	16	**Side-posts** (Figs. 177, 178)	6003	A.	--	----------	--	6 ft. 5 in. x 2¾ in. x 2 in.	Each having :—
					1	Tenon	a	2¼ in. x ⅞ in. x 2¾ in.	To fit into mortises (b) in side-sills, Plate IV., Fig. 49 — Double end tenoner and gainer
					1	Tenon	b	2½ in. x ⅝ in. x 2¾ in.	To fit into mortises on underside of side top-rail (6018), Fig. 163, not seen in the figure — Double end tenoner and gainer
					1	Gain	c	6 in. x ⅜ in.	For side sub-top-rail (6019) to fit in — Double end tenoner and gainer
					2	Rabbets	d	½ in. x ½ in. x 1 ft. 6⅛ in.	To fit side-post seat-end iron-panel (6502), Fig. 188 — Shaper
					1	Mortise	e	10¼ in. x 1 in. x ¾ in.	For seat division-board to fit in — Hollow chisel mortiser
					2	Pockets	f	3½ in diam.	For curtain edges to fit in when rolled up ; there is a counterbore 13-16 in. diam. in the center to receive the ends of the curtain-roller and the roller-sockets — Borer
					2	Grooves	g	½ in. x ½ in.	For the curtain-guides to slide in — Routing machine
					1	Bolt-hole	h	7-16 in. diam.	For reversible seat-back arm-pivot (9505) to hold pillar-handle middle-socket (6512) and reversible seat-back arm (9503) — Borer or multiple spindle drill
					1	Bolt-hole	i	⅜ in. diam.	For bolt to hold pillar-handle bottom-socket (6513) — Borer or multiple spindle drill
					1	Bolt-hole	j	7-16 in. diam.	For bolt to secure side-post seat-end iron-panel (6502) to side-post — Borer or multiple spindle drill
					1	Bolt-hole	k	½ in. diam.	For side-post tie-rod (6510) — Borer or multiple spindle drill
					1	Bolt-hole	l	7-16 in. diam.	For bolt to secure side-post seat-end iron-panel (6502) to side-post — Borer or multiple spindle drill
					1	Bolt-hole	m	⅜ in. diam.	For bolt to secure side-post strap-bolt (6508) to side-post, with counterbore ½ in. deep for the bolt head. — Borer or multiple spindle drill
					1	Pocket	n		For guard-rail catch finger (6515) to fit in, it is only in the third side-post from each end, making 4 in all — Borer and hollow chisel mortiser
					2	Grooves	o	⅛ in. x ⅛ in. x 20 in.	For wires to electric push-button (8616) — Circular saw
					1	Pocket	p	⅝ in. diam. x 7-16 in. deep	For electric push-button (8616) — Borer
									The mortises (n) in the side-sills, Fig. 49, being white-leaded, the side-posts are driven in and secured with
44	16	**Side-post strap-bolts** (Fig. 190)	6508	W. I.	--	----------	--	11 3-16 in. x 7-16 in.	Bolted and screwed to side-posts through holes (m), Fig. 181, with 16 bolts 3¼ in. x 5-16 in. and 16 No. 10 x 1¼ in. steel screws ; they are inserted in holes (i) of the side sills, Plate IV., Fig. 49, and tightened up with their nuts
45	2	**Side top-rails** (Fig. 163)	6018	Y. P.	--	----------	--	26 ft. 0 in. x 3 in. x 2¼ in.	Each having :—
					2	Tenons	a	2⅝ in. x 2 in. x ⅞ in.	To fit in mortises (i) of the corner-posts (6002) — Double end tenoner and gainer
					8	Mortises	--	2½ in. x ⅝ in. x 2¾ in.	To receive tenons (n) of the side-posts (6003); they are on the underside of the rail and not seen in the figure
					8	Gains	b	1⅞ in. x ⅞ in.	For lower-deck compound-carlines (7010) — Double end tenoner and gainer
					2	Gains	c	1¾ in. x ⅞ in.	For lower-deck thick-rafters (7011); these are next the corner-posts — Double end tenoner and gainer
					18	Gains	d	13-16 in. x ⅞ in.	For lower-deck thin-rafters (7012) — Double end tenoner and gainer
					1	Rabbet	e	⅝ in. x ⅜ in.	Running the whole length for side sub-top-rail (6019) to fit in — Molding machine
									These rails are adjusted to the corner and side-posts, and secured with 4 No. 16 x 3 in. steel screws to the former, and with hickory dowel-pins to the latter
46	2	**Side sub-top-rails** (Fig. 164)	6019	A.	--	----------	--	25 ft. 11⅜ in. x 6⅝ in. x ⅜ in	Screwed to side-posts through holes (a) with 64 No. 12 x 1 in. steel screws, and to corner posts through holes (b) with 12 No. 12 x 1 in. steel screws
47	2	**Side top-panels** (Fig. 165)	6020	P.	--	----------	--	26 ft. 4 in. x 5 11-16 in. x ⅜ in.	Nailed to side sub-top-rail (6019)
48	2	**Drip-rails** (Fig. 166)	6021	A.	--	----------	--	26 ft. 3¼ in. x 8½ in. x 1½ in.	Each having :—
					10	Pockets	a	1¼ in. diam.	For pillar-handle top-sockets to fit in ; the drip-rails are secured to the side sub top-rails (6019) by 98 No. 12 x 12 in. steel screws, screwed through holes (c) in the latter and through the side top-panels into the drip-rail — Borer
49	8	**Seat division-boards** (Fig. 167)	6022	P.	--	----------	--	6 ft. 8½ in. x 10½ in. x 1 in.	Adjusted to side-posts, and fitted in the mortises (e) of the side-posts (6003)

TABLE NO. 34—*Continued*

Consecutive Number	Quantity	Name of Piece	Piece Number Plates II. and VI.	Material See Plates I. and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate VI.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
					1	Groove	a	½ in. x ½ in.	Runs along the top edge for the side-post tie rod to lie in	Molding machine
50	8	**Foot-rail brackets** (Fig. 181)	6503	C. I.	..	.....	..		Bolted to the bottom of the seat division-boards, in their centre (6022), with 8 bolts 2¼ in. x ⅜ in., to hold the foot-rails	
51	16	**Foot-rails** (Fig. 168)	6023	A.	..	.....	..	6 ft. 7¾" x 1¼" octagonal	Inserted in the foot-rail brackets (6503); they are adjusted later. (*See Con. No. 53*)	
52	4	**Corner-post seat-end iron-panels*** (Fig. 187)	6501	M. I.	..	.....	..		In 2 pairs, each consisting of 3 pieces, shown and marked in the figures (a), (b) and (c), (b) being the piece next the front or platform, and (a) the piece toward the center of the car. The two pieces (a) and (b) are screwed to the corner-posts with 52 No. 14 x 1½ in. steel screws, the holes for the screws being under the covering piece (c), and fastened to the side-sills through tongues at the bottom on the other side of the panels with 24 lag screws 2 in. x ⅜ in., after which the covering pieces (c) are screwed to the corner-posts with 52 round-head, blued-steel screws No. 16 x 1½ in. There are in each:—	
					1	Groove	d	½ in. x ½ in.	In the covering piece (c) for the curtain-guides to slide in	
					1	Hole	e	⅜ in. diam.	In each panel piece (a) and (b) for seat bolt (9507)	
53	16	**Side-post seat-end iron-panel*** (Fig. 188)	6502	M. I.	..	.....	..		Each having:—	
					2	Grooves	a	½ in. x ½ in.	For the curtain-guides to slide in	
					1	Hole	b	⅜ in. square	For bolt 4⅜ in. long through side-post, with round-head on the outside	
					1	Hole	c	½ in. diam.	For side-post tie rod (6510)	
					1	Hole	d	⅜ in. square	For bolt 3¾ in. long through side-post, with countersunk-head on the inside.	
					2	Holes	e	⅜ in. diam.	For seat-bolt (9507)	
					4	Tongues	..		At the bottom on the inside (not seen) with holes in them for 64 lag screws, 2 in. x ⅜ in., to fasten the panels to the side-sills	
					2	Sockets	..		(Not seen) cast on the inside of the panels, corresponding to the foot-rail brackets (6503), Fig. 181, into which the round ends of the foot-rails are inserted, so that when the panels are fixed and tightened up, the foot rails are held securely in place. (*See Con. No. 51*)	
54	8	**Side-post tie-rods** (Not Ill.)	6510	W. I.	..	.....	..	7 ft. 3¾ in. x 7-16 in.	Are passed through hole (e) of the side-panel and side-post to and through the opposite side-post and side-panel, and tightened up with a nut at each end	
55	4	**Top-panel corner-plates** (Fig. 193)	6505	S. I.	..	.....	..	4¼ in. x 4¼ in. x 3¼ x 1-16 in.	Screwed to corner-posts, side and end top-panels with 32 No. 10 x 1 in. steel screws. Each one has	
					1	Hole	a	½ in. diam.	For platform-hood bracket (7505) bolt	Punch
56	4	**Sub-top-rail corner-plates** (Fig. 192)	6506	S. I.	..	.....	..	3 11-16" x 3 5-16" x 1¾" x 1-16"	Screwed to corner-posts, side and end sub-top-rails with 8 No. 10 x 1 in. and 24 No. 7 x ¾ in. steel screws	
57	4	**Side-sill wear-plates** (Fig. 194)	5507	M. I.	..	.....	..	18 in. x 2⅛ in. x 3-16 in.	Screwed to side-sills between the seat-end panels and in front of the corner-post panels with 132 No. 12 x 1 in. steel screws	
4		**Side-sill wear-plates** (Fig. 194)	5507	M. I.	..	.....	..	17 in. x 2⅛ in. x 3-16 in.		
14		**Side-sill wear-plates** (Fig. 194)	5507	M. I.	..	.....	..	14 in. x 2⅛ in. x 3-16 in.		
58	16	**Pillar-handle top-sockets** (Fig. 186)	6511	Bz.	..	.....	..		With 3 ears, and	
	4	**Pillar-handle top-sockets** (Fig. 184)	6511	Bz.	..	.....	..		With 2 ears, fitted to cavities (a) in the drip-rails (6021) and secured with 56 No. 9 x ¾ in. bronze screws; the 4 sockets with 2 ears being for the cavities at each end of the drip-rails	
59	12	**Pillar-handle middle-sockets** (Fig. 182)	6512	Bz.	..	.....	..		Screwed to corner-posts and the second and fourth side-posts from each end, with 12 No. 12 x 1¼ in. bronze screws, and further secured with the seat back arm-pivots (9505) going through holes (h) in the side-posts, Fig. 181, (*see Con. No. 43*) and to the corner-posts with 4 bolts 4⅝ in. x 5-16 in. with round beveled heads on the inside and bronze nuts on the outside	
60	2	**Guard-rails** (Fig. 169)	6026	A.	..	.....	..	27 ft. 0 in. x 2¾ in. x 1¼ in.	Are laid on the pillar-handle middle-sockets, between the side-posts and the pillar-handles, to which	
61	4	**Guard-rail guides** (Fig. 185)	6514	Bz.	..	.....	..		Have been previously screwed with 8 No. 12 x 1 in. bronze screws, one at each end of the guard-rails	
62	20	**Pillar-handles** (Fig. 174)	6025	A.	..	.....	..	4 ft. 0¾ in. x 1½ in. diam.	Are now passed through the pillar-handle middle-sockets, the guard-rail guides, and their top tapered ends fitted in the pillar-handle top-sockets, and secured in this position by their bottom ends being fitted in	
63	20	**Pillar-handle bottom-sockets** (Fig. 183)	6513	Bz.	..	.....	..		Which are screwed to the corner-posts with 4 No. 12 x 1¼ in. and 4 No. 18 x 1¾ in. bronze screws, and to the side-posts with 16 No. 12 x 1¼ in. bronze screws, and further secured to the side-posts with 16 bolts 3¾ in. x 5-16 in. with round beveled heads and bronze nuts, passing through holes (i) in the side-posts, Fig. 181. (*See Con. No. 43*)	
64	8	**Guard-rail catches** (Fig. 180)	6515	M. I.	..	.....	..		Screwed to the top of corner-posts and each third side-post from the end, over pockets (n), Fig. 181 (*see Con. Nos 38, 43*), with 32 No. 8 x ⅝ in. steel screws. When entrance to the seats is desired, the guard-rail is pushed up past the spring-finger, which then springing forward holds the rail secure; and when entrance to the seats is to be closed, the rail is lowered to rest on the pillar-handle middle-sockets	
65	8	**Guard-rail wear-plates** (Fig. 179)	6516	Bz.	..	.....	..	2½ in. x 1¼ in. x 1 in. x 1-16 in.	Are screwed to the guard-rail, with 16 No. 9 x ½ in. and 16 No. 7 x ½ in. bronze screws, where the rail rests on the top catch (6515)	
									The car body is now ready to receive the roof, which is described in Table 36 and illustrated by Plate VIII.

LEGAL NOTES AND COMMENTS

EDITED BY J. ASPINWALL HODGE, JR., OF THE NEW YORK BAR*

Some Recent Decisions

STOCKHOLDERS' LIABILITY

In two cases just decided by the Supreme Court of the United States, a much mooted question upon which courts have differed, has been decided, and perhaps in a way which is binding upon the courts of all the States.

Each State in the Union has a different set of provisions in its statutes, and some times in its constitution, creating, restricting, and defining the liability of stockholders of an insolvent corporation for its debts. In some States, as in West Virginia, this liability is so restricted as to be almost obliterated, while in other States, *e. g.*, Kansas, the conditions which create the liability are numerous.

The highest courts in many of the leading States have frequently refused to enforce a stockholder's liability against their own citizens when it was claimed that such a liability arose out of the statutes of another State in which the corporation was organized.

This policy has been ably defended, and has been as ably criticised. It would seem that the decisions in the two cases referred to, (*Whitman vs. the Bank, advance sheets S., P. 506*), especially the latter, will compel a reversal of this policy, for the court holds that when the laws of a State in which a judgment is rendered against a corporation organized in that State provide that it shall be binding on the stockholders, the courts of every other State must give that judgment the same conclusive effect against a stockholder, who is sued, as if he had been a party to the action in which the judgment was obtained, and the only defenses which the stockholder can make are those which he is allowed to interpose in the courts of the State in which the judgment against the corporation was rendered. This would seem to overthrow the rule in such cases as *Marshall vs. Sherman, 148 N. Y., 79.*

X-RAYS

A novel scientific question has been raised in a recent case where an application was made to require a plaintiff in an action for personal injuries, to submit his neck to the action of the X-rays, in order that the nature and extent of his injuries might be ascertained. It would seem that where an examination of the person is allowed by the court, that certain mechanical devices may be used by the physician, as for example, a measuring tape, a magnifying glass, the stethescope, or the various devices used to throw light into the mouth, the eye, etc., but the court was up against a new question when it was asked to compel the plaintiff to allow the physician to use the X-rays. It was insisted, in support of the particular application made, that the court should take judicial notice of the fact that exposure to X-rays is not injurious to the subject. While denying the application on other grounds, the court expressed a doubt as to whether science is sufficiently far advanced to justify the court in taking judicial notice of the claimed harmlessness of the action of the ray. It was held that the application was not seasonably made, and that it was affirmatively shown that the person who was to apply the ray had sufficient knowledge and experience to apply it properly.

DAMAGES CAUSED BY DELAY

A case recently decided in England is of interest to the common carrier and the traveling public. An English barrister sued the Metropolitan Underground Road for the inconvenience, loss of time and necessary expenditure in cab hire arising out of the fact that after the defendant's railway line had become blocked, the company sold him a ticket and allowed him to board a train, which, after running a short distance, was stalled. The court held that he had stated a cause of action, although it was obliged to deny him relief on the ground that he failed to prove that sufficient time had elapsed between the happening of the accident which caused the block down the line and the time when he purchased the ticket and his train was despatched.

Apparently, the court held that it was the duty of the common carrier to have proper telegraphic facilities, and having these, to notify the stations along the line of a blockade and to refrain from selling tickets or despatching trains which would only tend to delay its passengers.

STREET RAILWAYS AND STREET ASSESSMENTS

The street railway companies are liable for assessments along with the abutting property owners for the cost of street improvements is a proposition recently reiterated in the case of *Shreveport vs. Prescott, 55 La. Ann., 1895.* This is in accordance with what appears to be the preponderance of authority. But the liability of the street railway company for anything above the nominal amount which may be assessed for actual benefits conferred upon the company by the improvement is generally determined by the presence or absence of provisions in the franchise or contract under which it obtains the right to occupy a portion of the street, creating a contractual liability.

It was held in *Norwood vs. Baker, 172 U. S., 269,* by the Supreme Court of the United States that any assessment upon a property owner for improvements which are not limited to the benefits conferred by the improvement upon the property was in violation of the constitution of the United States. This, of course, does not affect the provisions of a franchise which compels the railway company to pay for street improvements over and above the benefit they may confer upon the property of the company, but in the absence of such provision it limits the possible assessment to the actual benefit derived.

It is manifest that the ordinary street improvement, such as paving or curbing the street does not confer any great benefit upon a street car line which may be operating in its center.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

NEW YORK.—Motive Power—Change—Abutting Property—Required Consent—Commission—Substituted Consent.

Under Laws 1890, chap. 565, sec. 100, providing that any change in the motive powers of a street railway must be consented to by the owners of one-half the abutting property, and in case such consent could not be obtained the determination of a commission appointed by the general term of the Supreme Court in favor of such motive power, when confirmed by the court, should be taken in lieu thereof, and that such consent should be obtained in the same manner as provided in sections 91 and 94 of the same act, which sections require that for the construction of a street railway the consent of the owners of one-half "in value" of the abutting property should be obtained, etc., a petition for a commission to authorize a change of motive power, alleging that the consent of the owners of one-half "in value" of the required property could not be obtained, was not insufficient because it did not show that the consent of the owners of one-half the "lineal front feet" of such property could not be obtained, since the evident intent of the Legislature was to conform the practice of obtaining the consent to a change in motive power to that required for the construction of a street railway.—(In re Rochester & L. O. Ry. Co., 64 N. Y., Suppl., 429.)

NEW YORK.—Pleading—Amendments—Misnomer of Defendant.

1. Under Code Civ. Proc., section 723, permitting amendments to pleadings upon the trial, or at any stage of an action before judgment, by adding or striking out the name of a party, or by correcting a mistake in the name of the party, plaintiff may be allowed to amend his complaint by correcting a mistake in the

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

name of a corporation defendant after appearance, and before trial.

Same—Waiver of Misnomer.

2. Under Code Civ. Proc., section 1777, providing that a mistake in the corporate name of a party to an action is waived unless the misnomer is pleaded in the answer, or other pleading in defendant's behalf, a defendant who has waived such mistake by failure to plead it cannot complain of the allowance of an amendment to the complaint correcting a mistake in the name of a corporation defendant.

Courts—Jurisdiction—Domestic Corporations.

3. The operation of a railway by a corporation within the territorial jurisdiction of the municipal court of the city of New York is sufficient to constitute a residence by such corporation within the jurisdiction of said court, under Code Civ. Proc., section 341, giving the County Courts jurisdiction of actions against domestic corporations actually located within the county.

Appeal—Issues in Lower Court—Estoppel.

4. Where the cause was voluntarily litigated in the court below upon the theory that two city ordinances of different years, and affecting the rights of defendant, were identical, the plaintiff will not be permitted to claim on appeal that the question of their identity was not properly raised in the court below because one of the ordinances was not introduced in evidence.

Street Railroads—Times for Running Cars—Construction of City Ordinances.

5. Rev. Ord. City of New York, 1897, sections 595, 596, requiring city railroad companies "not running cars" on the surface of the streets of said city to run not less than one car every twenty minutes between the hours of 12 midnight and 6 o'clock a. m., under penalty of $100 for every neglect or refusal to comply with the ordinance, are applicable to a street railroad which did not begin to operate its cars, nor have any corporate existence, until the year 1892; said sections being identical with an ordinance of said city adopted in 1890, before said corporation was "running cars," and Rev. Ord., section 785, providing that, in so far as the revised ordinances are substantially the same as the ordinances existing at the time the former took effect, they shall be construed as a continuance of such ordinances, and not as new ordinances.

Appeal—Questions Not Raised Below.

6. The claim that Rev. Ord. City of New York, sections 595, 596, in regard to the running of street cars after midnight, do not apply to defendant, in the absence of proof that it ran cars or had tracks laid at the time when the revised ordinances took effect, cannot be made on appeal, when such point was not raised in the court below.

Ordinance Fixing Time for Running Cars—Violation—Evidence.

7. In an action to collect a penalty of a street railway company for its neglect to run cars every twenty minutes after midnight, as required by Rev. Ord. City of New York, sections, 595, 596, evidence that in 1892, by a consolidation of certain street railroads, defendant became the owner of the road, tracks, etc., on W. avenue; that during the daytime of the period in question cars bearing defendant's name were run along said avenue, and that no cars except those bearing the name of defendant were operated thereon; and that on a day named in 1898, from half-past 1 until half-past 5 o'clock in the morning no cars passed a police officer, whose beat extended along said avenue, is sufficient to support a judgment for the penalty prescribed for the violation of said ordinance.—(City of New York vs. Union Ry. Co., of city of New York, 64 N. Y. Suppl., 483.)

LIABILITY FOR NEGLIGENCE.

NEW YORK.—Negligence—Extent of Injuries—Evidence.

1. Where plaintiff, an actress, suing for injuries sustained, testified that on joining her company, some weeks after the accident, she was so ill as to seldom be able to attend rehearsals, and was under a doctor's care all the time; that her manager well knew how ill she was, and that she was finally compelled by sickness to stop work, it was error to exclude testimony of the manager as to what he had observed as to her physical condition during that period.

Same.

2. Where plaintiff had testified that she was forced to disband her theatrical company through ill health due to injuries sued for, and not because of her incompetency as an actress, it was error to exclude the testimony of her manager as to why the company was disbanded.—(Farrell vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 709.)

NEW YORK.—Negligence—Instructions.

1. In an action for injuries caused by plaintiff's wagon colliding with a street car while he was driving across defendant's tracks, an instruction that if, just before the accident, the wagon was driven alongside the track and it was turned into the track in front of the car, the verdict must be for the defendant, was properly refused, since the turning into the track might have been far enough in front of the car to have given the gripman ample time to stop the car and prevent the accident.

Same—Special Damages—Allegation—When Necessary.

2. Where injuries for which recovery is sought do not necessarily result from those described in the complaint, they must be alleged as special damages; and an injury to plaintiff's eye could not be recovered for on an allegation of injury to the head and brain, since it did not necessarily result therefrom.—(Geoghegan vs. Third Ave. R. Co., 64 N. Y. Suppl., 630.)

NEW YORK.—Excessive Damages—Personal Injuries.

Plaintiff, a teacher, was injured by the sudden stopping of defendant's street car, on which she was a passenger, the injury being a dislocation of a cartilage in each knee, with other injuries to her body. She expended $1,670 for medical services, and was confined to her bed about ten weeks. At the time of the trial, eighteen months after the accident, she could not go up and down stairs without pain, and, in consequence of her condition, had to give up her position of general superintendent in a school. Held, that a verdict of $15,000 should be set aside as excessive.—(Kraemer vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 619.)

NEW YORK.—Malicious Prosecution—Evidence—Judicial Proceedings.

An action for malicious prosecution will not lie against a defendant for having illegally arrested plaintiff without a warrant, and having brought him before a police court, where he is discharged without the filing of a complaint; an essential element of malicious prosecution being a commencement of judicial proceedings.—(Barry vs. Third Ave. R. Co., 64 N. Y. Suppl., 615.)

NEW YORK.—Personal Injuries—Negligence—Evidence.

In an action against a street railroad company for injuries alleged to have been caused by snow or ice thrown by a sweeper used by defendant to clear the snow from its tracks, in the absence of proof that the snow or ice which had caused the injury and which plaintiff said came from the direction of the sweeper, did in fact come from the sweeper, and in the absence of proof that this was the result of negligence which could have been avoided, a verdict for plaintiff cannot be sustained.—(Connor vs. Metropolitan St. Ry. Co., 63 N. Y. Suppl., 509.)

NEW YORK.—Injuries—Negligence—Conflicting Evidence.

1. Where, in an action for personal injuries from being struck by a street car, the evidence, both as to defendant's negligence and plaintiff's contributory negligence, is conflicting, and sufficient to sutain a verdict for either party, a judgment entered on the jury's verdict will not be disturbed on appeal, as not supported by sufficient evidence.

Same—Speed of Car.

2. Where, in an action for injuries for negligent management of a street car, defendant claimed that the car was going but eight miles an hour, and plaintiff had already shown that it took 80 ft. in which to stop it, plaintiff's evidence that but 12 ft. would be required in which to stop a properly equipped car going eight miles an hour was admissible.—(McDonald vs. Brooklyn Heights R. Co., 64 N. Y. Suppl., 480.)

NEW YORK.—Accident at Crossing—Contributory Negligence.

Plaintiff, a motorman, in charge of an electric car, when about 750 feet from a railroad crossing, saw a freight train standing on defendant's track about 315 ft. from the crossing. At this time his car was moving at the rate of 12 miles per hour, and continued at that speed until within 125 ft. of the crossing, when he discovered that the train was backing toward the crossing and that there was danger of a collision. He reversed his power, put on the brake, and thereby reduced the speed, but could not bring his car to a stop before reaching the crosing, owing to ice on track, and, as a result, it struck the train, and plaintiff was injured. Held, that he was guilty of contributory negligence as a matter of law.—(Einsfield vs. Niagara Junction Ry. Co., 63 N. Y. Suppl., 563.)

NEW YORK.—Appeal.

Where, in an action against a street car company, defense was supported by testimony of two disinterested witnesses, a judgment for plaintiff will not be held against the weight of evidence where, in addition to her own evidence, she was entitled to the benefit of the presumption arising from failure of defendant to produce its motorman and conductor, who saw the act in question, without sufficient explanation of their absence.—(Staib vs. Union Ry. Co. of New York City, 62 N. Y. Suppl., 755.)

NEW YORK.—Appeal—Review—Dismissal of Complaint—Presumption.

1. In reviewing a judgment dismissing a complaint for insufficiency of evidence, all evidence offered by plaintiff must be taken as true.

Accident at Crossing—Evidence of Contributory Negligence.

2. A truckman, seeing an electric car standing about 100 ft. away, drove across the track in front of it, and was struck and injured by it. He had a lantern in front of his truck, throwing the light forward toward the horses. He did not see the car after he started to drive across the street. Held, that the question of his contributory negligence was for the jury.—(Lowry vs. Metropolitan St. Ry. Co., 62 N. Y. Suppl., 743.)

NEW YORK.—Injuries to Wife—Damages—Medical Attendance—Evidence.

1. In an action by a married woman for injuries, where it appears that she is living with her husband, and is not possessed of any private means or engaged in any separate business, evidence of the physician who attended her as to what his services were worth and what he was paid was incompetent.

Same.

2. In an action by a married woman for injuries, it was error to permit a physician to testify to plaintiff's physical condition as he found it two years after the injury, where it appears that the physician who attended her at the time of the injury did not discover the condition subsequently found to exist, and it further appears that she had, since the injury, given birth to two children, and that the condition found to exist on the second examination might have been caused by either of the intervening confinements. —(Sweeney vs. Union Ry. Co., of New York City, 64 N. Y. Suppl., 453.)

NEW YORK.—Appeal and Error—Case on Appeal—Insertion of Evidence.

1. An appeal from an order denying a motion for a new trial on the minutes raises the questions whether the verdict is excessive or contrary to the evidence, and hence, where plaintiff recovered for injuries, he is entitled to have all the evidence showing the extent of the injury, and the time he was disabled thereby, inserted in the case on appeal.

Same—Certificate as to Evidence—Review of Facts.

2. A certificate that a case on appeal contains all the evidence, only has place and effect where it serves as the only notice that review of the facts is sought, and is therefore unnecessary on an appeal from a judgment on a verdict of the jury and from an order denying a new trial, since such an appeal raises the question of the sufficiency of the evidence to sustain the verdict, and notice of the appeal is notice that the facts will be reviewed.—(Gibson vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 396.)

NEW YORK.—Attorney's Lien—Attorney and Client—Fees of Attorney—Value of Cause of Action—Compromise.

1. Plaintiff in an action for damages agreed to pay his attorney one-third of any sum for which the cause might be adjusted. A compromise was made between the parties, by defendant paying plaintiff a stated sum, and also agreeing to pay plaintiff's attorney any claim or lien on the cause of action which he might lawfully establish. Held, that the sum paid plaintiff in compromise was conclusive on the defendant as the value of the cause of action, in determining the amount to be paid plaintiff's attorney by defendant, and not such sum as might be established by a continuance of the action.

Same—Calculation of Fee.

2. Where plaintiff's attorney was entitled to one-third of any sum for which the cause might be adjusted, and it was compromised by defendant paying plaintiff $2,600 as a net payment, and agreeing to pay plaintiff's attorney the amount due him under such settlement, the attorney was entitled to a payment equal to one-third of $2,600 only, and not to a payment equal to one-half of $2,600, though, under his original agreement with plaintiff to receive one-third the amount recovered, his fee would be equal to one-half the net amount received by plaintiff.

Attorney's Fees—Stipulation—Summary Proceedings.

3. Code Civ. Proc., Sec. 66, as amended by Laws 1899, provides that an attorney shall have a lien on his client's cause of action, and that the "court upon the petition of the client or attorney may determine and enforce the lien." Held, not to give the court jurisdiction by summary order to enforce a compromise stipulation between plaintiff and defendant whereby defendant agreed to pay any lien which plaintiff's attorneys might establish on plaintiff's cause of action.

Same—Attorney's Lien—Enforcement.

4. Where plaintiff's attorney had a lien on his client's cause of action, and the case was compromised by defendant making plaintiff a cash payment and promising to pay plaintiff's attorney the amount of his lien, which he afterward refused to do, the attorney had the right to proceed to judgment in the action for the protection and enforcement of his lien.—(Pilkington vs. Brooklyn Heights R. Co., 63 N. Y. Suppl., 211.)

NEW YORK.—Attorney and Client—Attorney's Fees—Summary Proceedings.

A summary proceeding will not lie to enforce an agreement whereby a defendant, as part of a compromise, promised to pay the plaintiff's attorney his costs and fee.—(Schriever vs. Brooklyn Heights R. Co., 63 N. Y. Suppl., 217.)

NEW YORK.—Negligence—Driving in Front of Street Car. Where plaintiff saw a street car approaching about 250 ft. away, and drove on the track in front of it for a considerable distance, making no attempt to observe its approach, and his wagon was struck by the car as he was turning off the track, he was guilty of negligence.—(Pechesky vs. Metropolitan St. Ry. Co., 62 N. Y. Suppl., 478.)

NEW YORK.—Infants—Sui Juris—Negligence.

1. A 9-year-old girl testified that on stepping from the curbstone she saw a street car coming toward her; that she looked up because she thought she might get run over if she did not look; that she knew the car was a dangerous thing; that when she saw the car coming she thought she could get across; and that, as she stepped over the first rail, she knew nothing more. Held, that she was sui juris.

2. Evidence—Presumptions. Where a child was injured at a crossing by a street car, and the motorman was not called as a witness, it raises a presumption of his negligence.

3. Injury to Pedestrian. Plaintiff, 9 years old, attempted to cross a street in a well settled portion of a city, at a crosswalk, in front of a car about 127 ft. distant. When the motorman saw her, he brought the car to a standstill within 10 ft. or 15 ft. of the crosswalk where she was struck. Held, that the refusal of an instruction which assumed that there was nothing in the situation to justify her in the belief that the car would be brought under control before it arrived at the walk was proper, as at variance with the evidence.

4. Trial—Instructions. A refusal of a request to charge, where the court had already charged the matters requested so far as they were established by the evidence, was not error.

5. Contributory Negligence. Plaintiff's failure to defer crossing until the car had passed, or to continue to watch the car, did not constitute contributory negligence as a matter of law, but was a question for the jury.—(Hicks vs. Nassau Elec. R. Co., 62 N. Y. Suppl., 597.)

NEW YORK.—Collision—Action for Injuries. Plaintiff could not recover for injuries resulting from his wagon being struck by defendant's cable car, where he saw the car in time to stop his wagon, but miscalculated the distance, and attempted to drive in front of the car.—(Petri vs. Third Ave. R. Co., 62 N. Y. Suppl., 315.)

OREGON.— Pleading — Speed — Regulation — Ordinance — Amendment—Evidence.

1. Where a complaint to recover for the death of a minor child alleged that defendant was operating its street car at a dangerous and reckless rate of speed, there was no abuse of discretion in allowing an amendment that such a rate of speed was in excess of that permitted by a city ordinance.

2. Evidence of particular instances in which street railway cars were operated at a given speed is not admissible to show the speed of a car at the time of a collision with a child.—(Wade vs. City & Suburban Ry. Co., 59 Pac. Rep., 875.)

PENNSYLVANIA.—Collision With Vehicle—Contributory Negligence.

1. A driver on a narrow street, only 20 ft. wide from curb to curb, on which there were two tracks of an electric street railway, was overtaken by a car going in the same direction as he was driving. He turned onto the other track, driving along it up a hill. When the car approaching him from behind was beside his wagon, another car came suddenly into view from the other side of the hill, in front of him on the track on which he was driving, and ran into him. Held, that the driver was not guilty of contributory negligence, as a matter of law, in not stopping and waiting until the first car had passed him, and then returning to the track which he had left.

2. By the necessity of turning out of the track, the driver was suddenly placed, without fault on his part, in a position of danger; and, in his effort to extricate himself, he could not be held to the use of the best judgment.—(Cannon vs. Pittsburg & B. Traction Co., 44 Atl. Rep., 1089.)

PENNSYLVANIA.—Injury to Boy—Negligence—Briefs—History of Case.

1. Nothing should be stated in the history of the case not justified by the evidence.

2. The motorman, on discovering a boy on the step of the platform, should stop, and take him inside, or put him off; and his negligence in not doing so, intensified by his knocking on the window and kicking on the closed side, manifestly frightened the boy.

PENNSYLVANIA.—Collisions—Negligence. Where the speed of a street car is not unreasonable, and the motorman spares no effort to check it, so as to avoid collision with a person, who,

while proceeding near the track, suddenly attempts to cross ahead of the car, the company is not negligent.—(Sauers vs. Union Traction Co., 44 Atl. Rep., 917.)

PENNSYLVANIA.—Tipping Over Post—Negligence—Evidence—Instruction—Damages—Pain.

1. The question of negligence, where the trolley of a car left its wire, struck a span wire between two posts, and pulled one of them down on plaintiff, is for the jury, it depending on whether there was a useless and abandoned wire forming a loop on the span wire, in which the trolley caught, though only one person, who was not a dull or unveracious witness, testified to its presence, while the superintendent and several of the employees of the company testified that the loop was not there at the time of the accident.

2. An instruction authorizing an allowance in damages for pain and suffering, by way of compensation, is not error; there being no suggestion that pain and suffering had a positive price or market value.—(Bamford vs. Pittsburgh & B. Traction Co., 44 Atl. Rep., 1068.)

PENNSYLVANIA.—Moving Disabled Trolley Car—Negligence—Damages—Pain and Suffering.

1. Where the trolley of a disabled car, which was being pushed by another car, jumped its wire, striking and breaking a cross wire, thus causing the accident to plaintiff, the question of negligence is for the jury, on testimony that the proper course was to tie down the trolley of the disabled car, and that the conductor thereof was told by the conductor of the other so to do, but refused or neglected.

2. Pain and suffering are a distinct item for which damages may be awarded in a personal injury case.

3. The Supreme Court will grant a new trial on the ground of excessive damages, under Act May 20, 1891 (P. L. 101), only in very clear cases of wrong or injustice, which the court below should have remedied.—(Schenkel et ux. vs. Pittsburgh & B. Traction Co.)

PENNSYLVANIA. — Collision — Contributory Negligence. Plaintiff's team being struck by a car on the down track, coming from the direction in which he had been going on the up track, just as he turned onto the track, and the testimony being merely that he did not see or hear, and not that he looked, and it being a clear day, and manifest that he could have seen it for a long distance away if he had looked, contributory negligence prevents recovery.—(Bolhmer vs. Pittsburgh A. & M. Traction Co., 45 Atl. Rep., 126.)

PENNSYLVANIA.—Contributory Negligence. Plaintiff is guilty of contributory negligence where, after stopping his horse 10 ft. or 12 ft. from a street car track, whence he could see one-fourth of a mile, and seeing no car, he attempted to go forward, but, on finding his team stalled, backed up 10 ft. or 12 ft., and then went forward with a spurt, not looking again, with the result that he was struck by a car.—(Kern vs. Second Ave. Traction Co., 45 Atl. Rep., 125.)

PENNSYLVANIA.—Injury to Person in Street. Nonsuit is properly granted in case of one who, though seeing a car on the track, attempted to cross, she testifying that as she went to the edge of the track she saw the car was moving, and that the dasher was in front of her, and that she was at the side of car when struck thereby, as she must have been struck by her coming in contact with the car by her voluntary act.—(Walsh vs. Hestonville M. & F. Pass. R. Co., 45 Atl. Rep., 322.)

PENNSYLVANIA.—Action for Personal Injuries—Instructions—Damages.

1. In an action against a railway company to recover for personal injuries alleged to have been occasioned by its negligence, it is not error to state to the jury that it was defendant's duty to furnish reasonably skilled and competent men to operate its cars, and "that is just where the plaintiff claims the defendant failed in its duty."

2. In an action against a railway company to recover for personal injuries, an instruction authorizing the jury, in assessing plaintiff's damages, to consider the expenses incurred as a consequence of the injury, the inconvenience and suffering naturally resulting from it, and the loss of earning power, whether temporary or permanent, consequent on the character of the injury, without explanation of the evidence or law applicable to either item, is inadequate.—(Todd vs. Second Ave. Traction Co., 44 Atl. Rep., 337.)

TENNESSEE.—Personal Injuries—Accident Between Crossings—Right of Way—Res Gestæ—Credibility of Testimony.

1. Plaintiff, who had been struck by a street car, testified in an action for damages therefor that he did not look and listen before attempting to cross the track, but in a second trial he testified that he did so look and listen. *Held*, that the jury, and not the court, must determine the credibility of his testimony.

2. The plaintiff was struck by a street car, and about fifteen minutes was occupied in extricating and caring for him at the place of the accident, when the motorman stated that he saw plaintiff, but thought he would get off the track. *Held*, that the statement was no part of the res gestæ.

3. Between street crossings, a street railroad company's right of way is superior to, but not exclusive of, the right of a pedestrian.—(Citizens' St. R. Co. vs. Howard, 52 S. W. Rep., 864.)

UTAH.—Personal Injuries—Liability—Negligence—Custom—Instructions—Reasonable Care.

1. However unusual the method of a common carrier, such as a street railway company, in starting its cars, if that method is dangerous, and its use violative of the high degree of care which the carrier is required to observe regarding its passengers, and in the use of that method a passenger is injured, the carrier is liable.

2. In an action for damages for personal injuries alleged to have been caused by the defendant starting one of its cars, on which the person injured was a passenger, in a reckless, careless, and negligent manner, the question for the jury is whether or not in this particular instance the car was started in a negligent, dangerous, or improper manner; and an instruction which, in effect, charges the jury that, if the officers of the defendant, by experience, were satisfied in their own minds that the method used in starting the car was reasonably safe, defendant would not be liable, is erroneous.

3. In such a case, an instruction that "the defendant, being a carrier of passengers for hire, the law imposes upon it a reasonable degree of care and foresight to prevent injuries to persons lawfully traveling in its cars," is defective in not defining to the jury what, under the law, a reasonable degree of care is.—(Dickert vs. Salt Lake City R. Co., 50 Pac. Rep., 95.)

UTAH.—Damages—Personal Injuries—Evidence—In Rebuttal—Contributory Negligence—Instructions—Negligence—Further Instructions.

1. In an action for damages for personal injuries caused by being run into by a street car, it is proper for plaintiff to prove in rebuttal a statement made by defendant's witness, who was motorman, immediately after the accident, at the place where it occurred, and in the presence of plaintiff and defendant's agents in charge of the car, which statement is inconsistent with the testimony of such witness from the stand.

2. Although plaintiff may have been negligent, yet if nevertheless the defendant could, by the use of proper and ordinary care, have prevented the injury, an instruction that "if in the hurry of the moment, or in a moment of forgetfulness, the plaintiff attempted to cross the track, without exercising that care which a man of ordinary prudence ought to exercise under the circumstances, he was guilty of contributory negligence, and cannot recover," is properly refused.

3. In such a case, an instruction that "if you believe from the evidence that the defendant's motorman had the least opportunity to avoid the accident after the negligence of the plaintiff, and failed to use all reasonable means to avoid the same, the defendant would be guilty of negligence, and would be liable," is properly given.—(Shaw vs. Salt Lake City R. Co., 59 Pac. Rep., 552.)

VIRGINIA.—Street Railway Crossings—Injury from Low Trolley Wire—Contributory Negligence.

1. Where plaintiff, a brakeman on a railroad crossed by an electric street railway, knew that the trolley wire sagged so low that it was necessary to stoop in order to pass under it with safety while on the top of the car, his ignorance of the danger attending contact with an electric wire in no way excused his fault in failing to exercise that reasonable care which would have enabled him to pass beneath the wire with safety.

2. An instruction that, though plaintiff was guilty of negligence that contributed to the accident, he could recover if the defendant, the street railway, could have, by ordinary diligence, avoided the accident, was not applicable to the facts.

3. Where a brakeman on a railroad crossed by defendant electric street railway attempted, in the performance of his duties, to pass from one car to another, while passing under the defendant's trolley wire, and was struck by the wire, which sagged to within a few feet of the top of the car, he cannot recover for such injury, though the defendant was negligent in so maintaining its wire over the railroad.—(Danville Street Car Co. vs. Watkins, 34 S. E. Rep., 884.)

VIRGINIA.—Action for Injuries—Trial—Instructions—Objections—Waiver—Pleadings.

1. Where the evidence in an action for injuries caused by defendant's alleged negligence in running its electric cars was conflicting, an erroneous charge that plaintiff was entitled to recover if her injury "was caused by defendant's servants," and without want of ordinary care on her part, was not cured by a subsequent correct charge that the mere fact that the injury was caused by

defendant's car would not entitle her to recover unless it was also shown by a preponderance of evidence that defendant was negligent.

2. It was error to charge that though plaintiff, in stepping on the track, failed to look and listen, she could recover, if by looking or listening she could neither have seen nor heard the approaching car, where there was no evidence on which it could be predicated.

3. An objection that an instruction assumes facts not in evidence is waived where instructions given at the request of the objecting party assume the same facts.

4. A complaint which alleges that plaintiff was struck by defendant's electric car while she was on the track, "upon which she had just stepped," is demurrable, since it conveys the idea that the collision was simultaneous with the plaintiff's act in stepping on the track, and therefore shows contributory negligence.—(Richmond Traction Co. vs. Hildebrand, 34 S. E. Rep., 888.)

PATENT DECISIONS

Patents—Validity and Infringement—Electric Railway Contact Devices.—The Anderson patent, No. 412,155, for an improvement in electric railway contact devices, consisting substantially in interposing metallic spring brushes between the forks of the trolley arm and the hub of the contact wheel, so as to encircle the spindle and bear upon the end of the hub, for the purpose of transmitting the current from the wheel to the trolley arm, construed, and *held* to show meritorious and patentable invention over the prior devices of the Heysinger patent, No. 395,607, and the Vandepoele patents, Nos. 396,310, 397,451 and 408,638; and also *held* infringed.—(General Electric Co. vs. Rahway Elec. Light & Power Co., 96 Fed. Rep., 464.)

PATENT DECISION.—Patents — Infringement — Trolley Tracks.

Claim 1 of the Coburn patent, No. 365,240, for an improved trolley track, as narrowed by amendment, while the application was pending in the Patent Office, to meet the objection of want of novelty and invention, covers only the specific device described, which consists of a tube "having the lower edges curved in toward the median line, and then turned upward, so that the bottom of the tube has a rounded trough at each side of a longitudinal central opening," and is not infringed by a tubular track similar in other respects, but having the sides turned in at right angles, leaving a flat surface for the track on each side of the opening, and fairly adapted to rollers with flat faces.—(Coburn Trolley-Track Mfg. Co. vs. Chandler et al., 97 Fed. Rep., 333.)

The Manhattan Railway Company, of New York, in the building of its mammoth steam-electric power station, has awarded to the Harrisburg Foundry & Machine Works, the contract for the engines to operate the exciter dynamo in its new Seventy-seventh Street power house. Ordinarily an order for engines simply to operate exciters would be a small affair, but in this case, on account of the huge proportions of the plant, it amounts in the aggregate to 1600 hp, quite a power plant in itself. This was an order that attracted unusual attention among both users and builders of engines, for the new station, where the engines are to be installed, is designed to be second to none in the completeness of its equipment, and no pains were spared in the selection of the very best machinery of all types for the various services required.

The exciter engines are four in number, each of 400 ihp capacity, each direct connected to a 250-kw direct-current dynamo of the Westinghouse Electric & Manufacturing Company's make. These dynamos have eight poles, are wound for a 1000 amps. at 250 volts, and are guaranteed for an efficiency of 93 per cent.

The Harrisburg engines are of the tandem compound type, the cylinders being 14 ins. and 25 ins. diameter by 18 ins. stroke. They are to operate at a speed of 200 r. p. m., with 150 lbs. steam pressure condensing.

Improvement in Bergen County.

The opening of the new Hackensack line of the New York & New Jersey Railway & Ferry Company, the new name of the Bergen County Traction Company, was chronicled in the issue of the STREET RAILWAY JOURNAL for June 23. The company is also making a number of additions to its power station and rolling stock. In the power station, which is at Edgewater, the company is placing two new batteries of boilers of 750 hp each, or a total of 1500 hp, together with a new generator of equal capacity. This gives an additional power greater than the entire output of the old plant. The boilers will supply the necessary steam for a cross-compound Hamilton-Corliss engine of about 1500 hp. The company also contemplates making a further increase next December. This would have been done at the present time, but for the inability to secure machinery from the manufacturers.

New Publications

Historic New Hampshire. 62 pages. Published by the Exeter, Hampton and Amesbury Street Railway Company. Illustrated.

This interesting pamphlet contains much historical information regarding the territory covered by the lines of the company, and describes in a pleasant manner the various "sights" which may be observed by the passengers on the road. Although intended primarily for these patrons, a complete, illustrated description of the power plant, etc., is given at the end. Numerous half-tones are distributed throughout the text, and a map of the railway is included.

Trolley Trips In and About Fascinating Washington. By Katharine M. Abbott. Published by J. F. Jarvis, Washington, D. C. 127 pages. Illustrated. Price 10 cents.

This entertaining little book is quite a complete guide to the public buildings and other points of interest around the capital, as well as being very useful to those who wish to find the pleasantest and most convenient way of getting around. The principal goals of the sightseer are well illustrated and described. In the back is found a folding map of the city with the various trolley lines designated thereon, and the back cover contains a map of the city and suburbs.

Railroad Construction, Theory and Practice. By Walter Loring Webb. Published by John Wiley & Sons, New York, 46 pages. Illustrated. Price $4.00.

Intended for a text-book and not a reference book, this volume is perhaps of less value to the practical engineer than to the student; but it may well find its way to the engineering office on account of its concise explanations and numerous references to original scientific papers. The parts of the book devoted to practice have necessarily been largely taken from such papers, and, with possibly the single exception of the chapter on tunnels, represent the most modern methods and figures. It is unfortunate that nothing is said about track in paved streets and bonding, although the subject of street railways is not supposed to be covered. The last quarter of the book is composed of tables, and an ingenious cardboard slide rule is found in a pocket on the inside of the back cover. The slide rule is intended for the computation of complicated earthwork problems, but the author fails to warn the student against too free a use of it in actual calculation. Many of the tables have been specially computed, and their excellent typography makes them a feature of the volume.

Modern Electric Railway Motors. By George T. Hanchett, M. E. Published by Street Railway Publishing Company, New York City. 200 pages. Illustrated. Price $2.00.

This book relates entirely to the description, design and management of electric railway motors, the author assuming from the first that the elements of electricity and magnetism have been previously understood. Although, perhaps, not intended primarily for a text-book, the arrangement is such that it would prove satisfactory in class-room work. The subject is treated in a strictly up-to-date manner, the latest apparatus, both American and foreign, being described, as well as a few of the older motors which are still in use. The excellent educational method of comparing the advantages and disadvantages of each set of systems or apparatus as it is explained is pursued throughout the work, and all abstract descriptions of the various types of fields, armatures, etc., are invariably followed by references to actual machines, thus fixing in the mind of the reader their application. The chapter on management and repair contains many useful hints for the car house and shop; and that on design, with its complete calculation for a modern type of motor, although necessarily not exhaustive, will be found of service to those entering this field. A folder in the back, giving authentic dimensions and other important data of all the best makes, will be welcome to both manufacturer and railroad man. The illustrations are numerous and good, and what is said is well said.

As an evidence of progress in Western engineering, it may be noted that the city engineer of Chicago recently placed with the Bethlehem Steel Company an order for a hollow-forged shaft to replace a breakdown in the North Side pumping station at that city. The new shaft, which measured 13 ft. 8½ ins. in length, 19 ins. in diameter, and weighed close to 10,000 lbs., was booked on May 30, and, under special emergency instructions, was hollow-forged, annealed and rough-machined in time to go forward June 9.

Many of the power stations in Chicago and other Western cities are equipped with shafts of this description, but this is the first time a hollow forging has been specified for water works engines in that section of the country.

Steel Rolling Doors

The cuts on this page illustrate a type of door which is peculiarly adapted to requirements of a car house. The manufacturers have increased its value for such uses by the addition of several ingenious devices which automatically insure a continuous trolley wire when the door is open, without in any way interfering with its operation.

The detail drawings show this arrangement; one with the door open, the other with it closed. The trolley wires on both the outside and inside are fastened to insulated blocks (*c*, *c* in the figure) which are connected by means of a wire running around the roller on which the door is coiled, and through a hole in the wall of the building. When the door is open the angle bar (*b*) fastened at right angles to the lowest segment fits over the guides (*a*, *a*), and forms a continuous path on which the trolley may run. To remove the strain from the blocks (*c*, *c*) guy wires, with turn buckles, are run out a few feet to the trolley wire from the wall.

The roller for the door is supported on strong brackets, and is revolved by means of an endless hoist chain and train of gears. As the sides require only a small groove to run in, every portion of the space is economized. When the door is up the entire opening is available. It is claimed that no matter how large this opening may be, it can be similarly treated, a door being now in process of construction which is 36 ft. wide by 20 ft. high, weighs 6200 lbs., and is probably the largest ever built.

A photograph of the car house of the Sioux City Traction Company, Sioux City, Ia., is reproduced to show the general appearance of the equipment in operation.

The doors above described are made by the Kinnear Manufacturing Company, Columbus, Ohio, which is the sole manufacturer.

CAR HOUSE AT SIOUX CITY

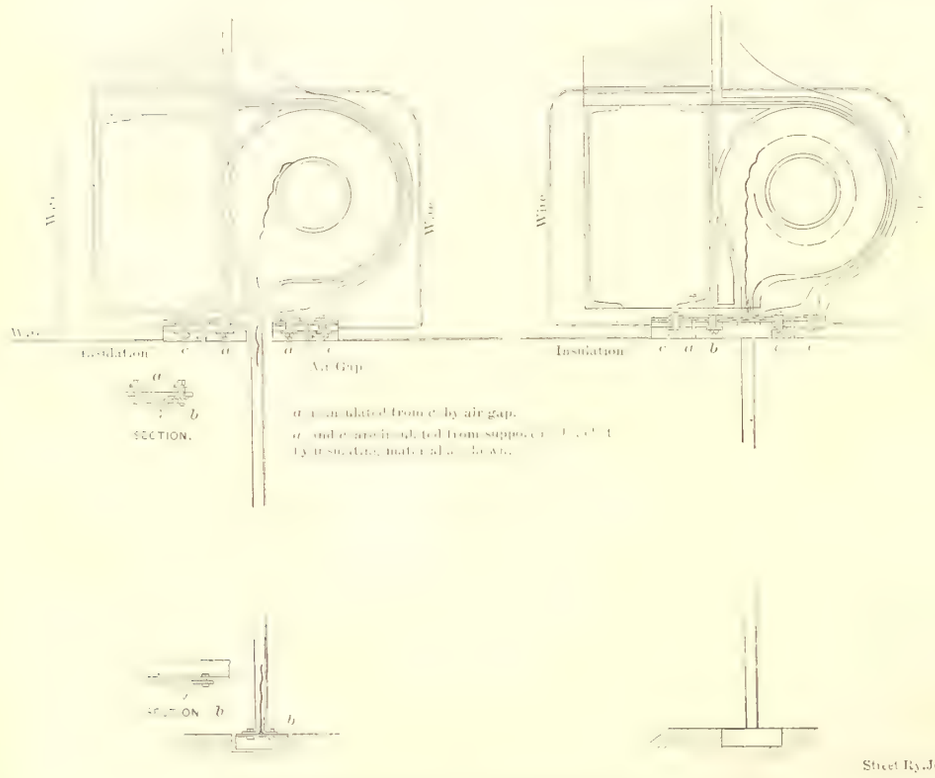

DIAGRAM SHOWING ARRANGEMENT OF DOORS

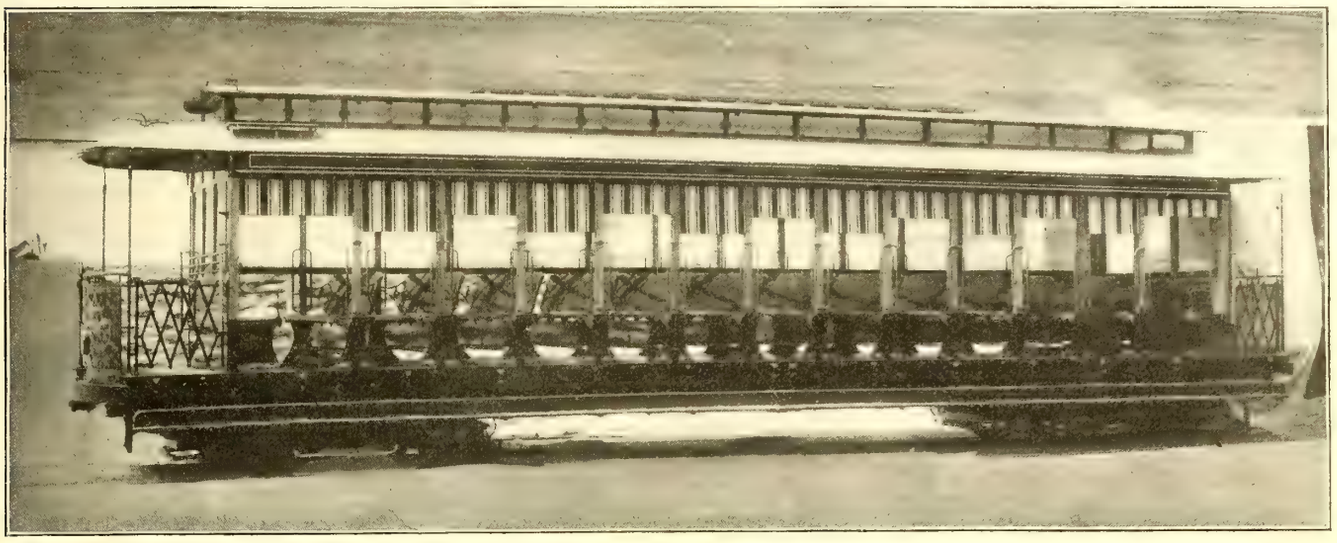
Some Recent Foreign Orders

The Morris Electric Company has been responsible for quite a large proportion of the exports of electrical apparatus which the daily papers have been mentioning for the past six months. Among other contracts which this company has made, and to which material has been shipped during the past six months, has been the supply of all the trolley, feed and span wire for the equipment of the Havana Street Railway Company. This company, as is well known, is building a large system in the capital of Cuba, and the feed wire contracts alone, it is said, involve an expenditure of over $200,000. For the same road the Morris Company has also filled an order for 2200 iron poles with brackets, fittings and appliances, 45,000 ft. of iron standard span wire, and 60 carloads of terra cotta ducts. These orders were placed with the Morris Company by George F. Greenwood, general manager of the Havana Street Railway Company. Two other railway companies for which Mr. Morris and the Morris Electric Company have supplied a large part of the material have been the Federal Street Railway Company, of Mexico City, and the Lisbon Tramways Company, of Portugal, both of which are controlled by the London bankers, Wernher, Beit & Company.

The Morris Company has also done a large amount of other foreign business in Europe, Africa and South America.

Large Open Cars

The engraving given herewith shows a fourteen-bench open car recently built for the Buffalo Railway Company, Buffalo, N. Y., by the J. G. Brill Company. These cars are interesting on account of their great size and the fact that they are mounted



LONG OPEN CAR FOR BUFFALO

on No. 27-F trucks. They are driven by four G E-57 motors ,and weigh without equipments 24,500 lbs. The trucks weigh about 5500 lbs. each. They are equipped with electric brakes and have electrice headlights. Bronze trim is used throughout, except for the grab handles, which are of malleable iron. There are two Dedenda gongs. Brill gates inclose the platforms, and the curtains when down reach to the floor.

The peculiar forms of the grab handles and inside guard rail are due to the great size of the cars. They are 41 ft. 10 ins. over the corner posts. Having a platform 3 ft. 8 ins. wide, they measure 49 ft. 2 ins. over the dashers. The extreme width is 8 ft. 2½ ins. The running boards are 19½ ins. from the head of the rail, with a 17-in. riser. The width gives 7 ins. more space on a seat than is usually allowed for five persons, making it possible by tight squeezing to put six passengers on a seat, although the nominal seating capacity of the whole car is but seventy. The step or running board is divided or closed in the centre and closes against the side of the car. The trolley board is insulated from the body of the car and the sound of the trolley deadened by the use of rubber.

Smokers will find the cars provided with one unusual little convenience—a match striker on the post. In designing these cars the management intended to provide seating capacity sufficient for all the passengers the cars were to carry, and made no provision whatever for standing room.

The New York & New Jersey Railway & Ferry Company, of Undercliff, N. J., has just purchased a large number of fine open cars, each equipped with four G. E. 67 motors, and mounted on Peckham 14 B 3 trucks. All trucks are fitted with the Price momentum brake, built by the Peckham Company, and which has proved very efficacious on the many grades on the line. Arc headlights are used.

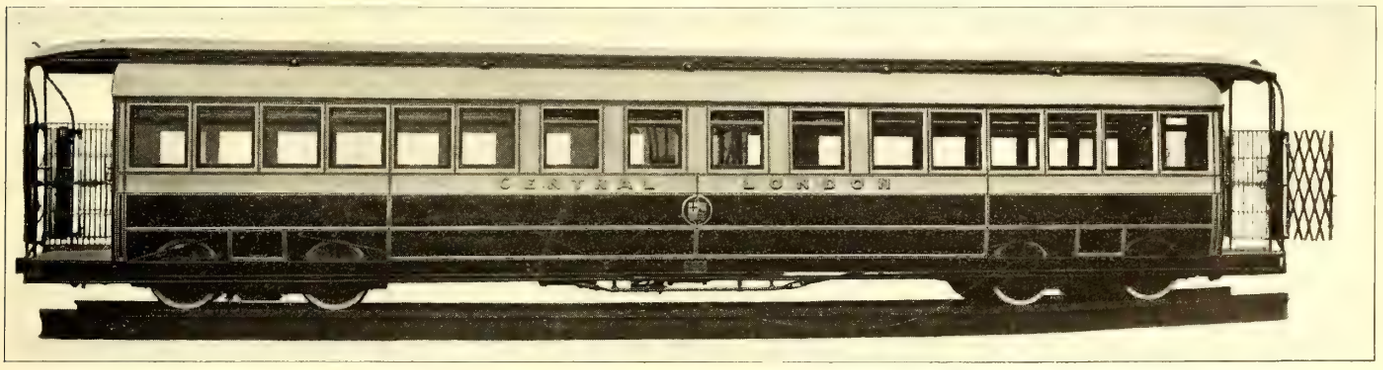
Central London Railway Car

Frequent reference has been made in the STREET RAILWAY JOURNAL to the Central London Underground Railway of London, and through the courtesy of the Brush Electrical Engineering Company, Ltd., of London, a view of one of the new cars, recently completed by this company for service on the Central London road, is given.

The main dimensions of these cars are:

Length over buffers	46 ft. 3 ins.
Length over headstocks	45 ft. 6 ins.
Length over body	39 ft. 0 ins.
Width over panels	8 ft. 6 ins.
Width at roof line	8 ft. 3 ins.
Height inside at middle	7 ft. 5 ins.
Center to center of bogies	29 ft. 6 ins.
Wheel base of bogies	5 ft. 0 ins.
Diameter of wheels on tread	2 ft. 5 ins.
Size of journals	6 ins. x 3 ins.
Center to center of journals	6 ft. 0 ins.
Gage	4 ft. 8½ ins.
Seating capacity	48 passengers

The seats are arranged longitudinally at each end with suitable arm rests, and at the center there are four rows of cross seats; this arrangement is necessary to allow the wheels to swivel under the



CAR FOR CENTRAL LONDON UNDERGROUND RAILWAY

longitudinal seats, as the cars are to run with ample clearance in an 11-ft. 6-in. tunnel, with the rails laid at a height of 1 ft. 7½ ins. from the invert of the tunnel. The seats and backs are provided with Wood's woven wire frames and upholstered in blue and crimson moquette velvet. The inside of carriage is paneled on the sides and ends with best white sycamore veneer; the panel framings are of light colored teak with teak moldings to match. The roof is arranged in three panels longitudinally and are covered with millboard ¼ in. thick, each panel having an ornamental lincrusta border carried along the sides and ends. Hand straps for the use of passengers are secured to a teak rail running the whole length of the carriage on the sides of the clere-story.

Brass baggage racks made of expanded metal, as well as hat and coat hooks, are provided along each side of the car. The whole neatly finished and lacquered. Ample ventilation is secured by means of hit-and-miss ventilators fitted to the sides of the clere-story, and hinged ventilators directly over the windows. In

addition ten "torpedo" air extractors (five along each side of roof) are used.

The roof is supported by channel steel carlines, and further strengthened at the center by two T steel arch bars, carried across the roof and down the sides of each cant rail. These carlines are covered with ornamental teak facings.

The whole of the body framing is made of well seasoned teak,

DUPLEX CAR FOR SOUDERTOWN

the side framing is trussed with diagonal braces, strap bolts and vertical tie rods.

The whole of the underframe is of rolled steel channel section, firmly bound together with knees and gusset plates.

The truck frames are of pressed steel made by the Leeds Forge Company. The truck centers are of cast steel with ample wearing surface and are mounted on spring bolsters also of pressed steel.

The axles are of best Siemens-Martin steel with wheel seats 4 ins. in diameter. The tires are 4½ ins. wide x 2 ins. thick and of Siemens-Martin steel. The wheels have wrought-iron bosses with teak centers and have Mansell's retaining rings. The wheels are forced on to the axles by hydraulic pressure of not less than 50 tons, without keys.

The cars are arranged with platforms at each end 3 ft. 3 ins. long with Gold's American automatic locking gates on each side of platform. The platform is further protected by iron screens 4 ft. 6 ins. high, with cross-over protected by chains. As a further safeguard a collapsible gate is fitted at opposite corners of each car, preventing passengers getting between the cars.

Each end of each car has a special arrangement of draw and buffer gear with India rubber springs and steel recoil springs. The whole of the drawgear is of best Yorkshire iron.

The cars are fitted with the Westinghouse quick acting brake with brake rigging of best hammered scrap, and all joints and pins properly case hardened.

Each car is fitted with ten electric lamps on two circuits, eight being inside and one at either end over the gangway, with junction boxes and flexible couplings between each car. Two oil lamps are fitted over each door for use in case of emergency.

The outside of the carriage is painted similar to the London & Northwestern Railway Company's stock. The body below the waist panels is painted purple lake, the waist panels and upwards are painted white and the moldings are painted purple lake throughout, with gold lines along the edges.

The end coaches of each train are arranged as smokers. They are upholstered in maroon haircloth and are provided with special drawgear for attaching to the electric locomotive.

Foundations have just been completed by the United Railways & Electric Company, of Baltimore, Md., for some very extensive repair shops in that city.

Duplex Car for Soudertown, Pa.

The accompanying engraving shows a combination open and closed car of the Duplex type, made by the Duplex Car Company for the Inland Traction Company, of Soudertown, Pa. The car is one of several of the same type built for this road, and is shown as an open car. The panels, of course, are slid up into the roof and can be dropped down within a very few minutes, and thus convert the car to closed car if desired. This feature of the ability to change the car quickly from open to closed and vice versa is one upon which the manufacturers of the car lay a great deal of stress. They claim that where the panels are detached from the car and stored during the summer, the main advantages of a duplex car is lost, as there are many times during the summer, as well as during the spring and fall months, when a quick change is desired, and if the panels are stored and have to be brought out and attached to the car to convert it, the delay in doing this will be so great as to lose the advantage in making the change. Again, when parts of this kind are stored, the chances of detioration are certainly as great, if not greater, than when they are carried on the car always ready for use.

The company reports doing an excellent business, and has recently been receiving orders for cars of the same type as that shown in the engraving from roads in Bellows Falls, Vt; Nelson, British Columbia; Lincoln, Neb.; Gardiner, Mass.; Allentown, Pa.; Buffalo, N. Y.; Schnectady, N. Y.; Bordentown, N. J.; Wilmington, Del., and elsewhere, as well as from roads abroad.

A Massachusetts Suburban Car

The accompanying engraving shows a type of car which has proved quite popular upon a number or roads in Eastern Massachusetts. The car shown is one built by the Laconia Car Company for the Blue Hill Street Railway, but the same car is used on the Brockton & Plymouth Street Railway and others.

CLOSED CAR FOR BLUE HILL

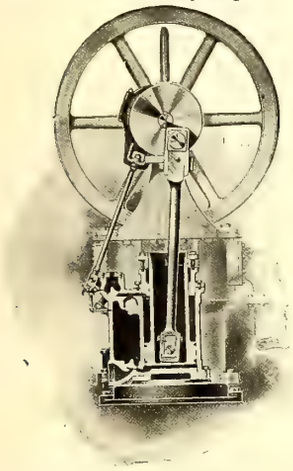
The car measures 40 ft. over all and has straight sides sheathed like steam railroad cars. There are ten double sash windows on each side, both sash being arranged to drop flush with the window sill. As the window sill is only 27 ins. above the floor, this makes practically a summer and winter car. There are ten reversible seats on each side, upholstered in rattan. The interior of the car is finished in quartered oak. The cars are furnished with the Laconia double trucks and Christensen air brakes.

Combined Air and Circulating Pump

The accompanying illustration shows a new combined air and circulating pump, recently brought out by the Conover Manufacturing Company, of New York.

The demand for economical results in modern power plants is rapidly extending to all parts of the equipment. Too little attention has been paid to the auxiliaries, and wide awake owners are no longer content to have only the main engines of the most efficient design, but insist on equal economy throughout. None of the parts of a modern plant is more important than the condensing apparatus, and especially in a surface condensing arrangement it is essential that the air and circulating pumps be of the most economical design in order to get efficient results. The air and circulating pump illustrated is very heavy in design, and being operated by a compound Corliss condensing engine the economy naturally is of a high order.

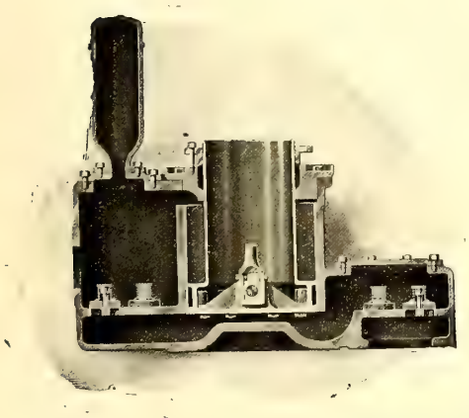
This engine is the same as used on the Conover jet condenser, which has proved its efficiency by years of use in the numerous large plants both here and abroad. The air pump is the regular Conover pattern, vertical, single-acting, and is made amply large for the slowest revolutions required to give the proper amount of water through the circulating pump. The pumps are arranged to vary the speed to give the proper amount of circulating water through the surface condenser at all times, the air pump taking care of itself. The air pump, excepting for the slight difference in friction, requires practically the same power to operate it without reference to the speed. As the same water and air are delivered in each case, a faster speed merely delivers a smaller quantity at each stroke, and proportionately reduces the mean effective pressure. This arrangement, therefore, gives all the advantages of separate air and circulating pumps in a combined machine, with less work to look after them and a much higher grade of economy.



CROSS SECTION OF ENGINE

The circulating pump is of the double acting, trunk displacement type, which gives a very steady discharge, and only requires one set of suction and discharge valves.

A cross section of the engine is shown. It will be seen on examination that this engine is compound condensing in one cylinder, and only takes steam once for a full revolution.



COMBINED AIR AND CIRCULATING PUMP

Long Cars for Rochester

The Jackson & Sharp Company, of Wilmington, Del., has just completed a number of long suburban cars for the Rochester & Sodus Bay Railroad, of Rochester, N. Y. The cars are illustrated herewith. The passenger cars, six in number, are 35 ft. long in frame, and 44 ft. 6 ins. over all. They are fitted with vestibules and side folding doors at each end. The interior finish is of quartered oak, in neat design, with carved mouldings, etc. They also have basket racks like those used in steam cars. In one end of the car a smoking room is provided. This room is more on the style of the smoking compartments in Pullman cars than anything yet attempted in cars for electric service. The distance of three win-

INTERIOR OF CAR

PASSENGER CAR

CAR WITH LARGE BAGGAGE COMPARTMENT

dows at one end is appropriated for this smoking compartment, and the entrance is from the platform.

At the end of the car are placed two hinged doors, one leading into the car proper through a passage way along the side of the car, and the other into the smoking room, which is provided with side slat seats, having seating capacity for eight to ten passengers. This room is also fitted with basket racks as well as coat and hat hooks.

CAR WITH SHORT BAGGAGE COMPARTMENT

The passenger end of the car is fitted with cross seats, upholstered in rattan. The windows are fitted with Pantasote curtains, made by the McKay Curtain Company, and fitted with patented fixtures. The car has seating capacity for forty-five passengers.

Owing to the large amount of country produce and baggage carried by this road, it has also ordered from the Jackson & Sharp Company eight combination passenger and baggage cars, as shown in the engraving above. These cars are like the passenger cars described above, except that 10 ft. of the space is appropriated for the baggage compartment, leaving 25 ft. for passenger service. The seating capacity of the passenger compartment is thirty-six, besides room for smokers in the baggage room, where folding seats are provided.

Four cars like those illustrated in the third engraving were also built for this road. These cars are also 35 ft. in frame and 44 ft. 6 ins. over all. Only 10 ft. of this space is appropriated for passenger service, and the balance, or 25 ft., is used for freight, produce, etc. The Jackson & Sharp Company is also building ten fifteen-bench open car bodies for the Rochester & Suburban Road.

The Wastefulness of Chimney Draft

In a recent editorial discussion of the question of the various methods for the utilization of waste heat, the *Engineer* considers, among other features, the usual method of producing draft by the ascent of heated air in a chimney.

Taking the boiler as the wasteful member in a steam plant, its efficiency varies from 60 per cent in a bad boiler to 80 per cent in a very good one, these proportions of the heat produced by the combustion of the coal being realized in steam available for the engine in each case.

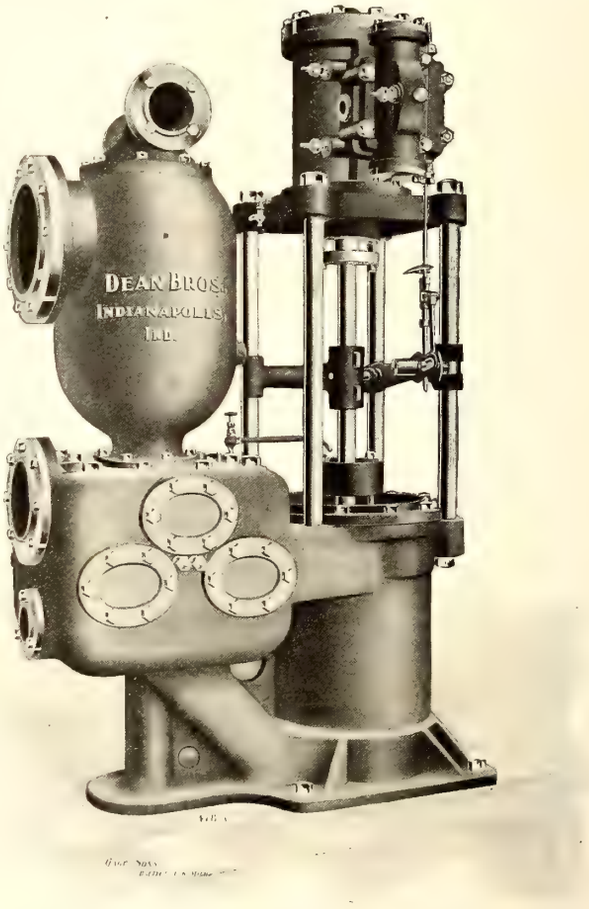
"The difference may be said, without greatly stretching the truth, to go up the chimney. It is not to be disputed that much of the waste heat might be caught and utilized, but there are reasons why it is not so caught. In the first place, the gases must be hot when they go into the chimney, or there will not be a draft.

"As a matter of fact, a draft got in this way is the most expensive possible, save one. The exception is a steam jet in the chimney. A fan can be run for about one-tenth of the power represented by the waste heat required to command a good draft. A tall chimney will cost from $5,000 to $25,000—very much more than will a fan plant. But the fan is not used and the chimney is, largely because it is essential to discharge the products of combustion high up in the air over the roofs of surrounding houses. This necessity must be taken into account in so far as factories are concerned, but it does not hold good of steamships; yet we believe that in most cases a chimney stack 100 ft. high would be sufficient, because with a fan, combustion could be more easily controlled than is possible with a chimney, to the end of preventing the giving off of smoke."

Vertical Double Acting Air Pump and Jet Condenser

It was formerly supposed that a vertical air pump must be single acting, but Dean Bros., of Indianapolis, have perfected a vertical air pump that is double acting, and is therefore double the capacity of a single acting air pump of the same dimensions. A view of this machine is given herewith. It is especially adapted to the requirements of high pressure, high speed engines, and is claimed to be more economical, more efficient, simpler and safer than than air pumps connected to the engine.

It is started before the engine, and the vacuum obtained is used to assist in the first revolutions. This feature is almost indispensable with triple expansion engines, as the full power of the low-pressure cylinder is secured at once. It adds nothing to the load of the engine, and takes less than half the power of a pump operated by the engine. The air pump is bronze lined, and has a bronze piston rod. There are no valves in the piston, all the valves being in the water chest at the side where they are quickly accessible. It is claimed to save 20 to 30 per cent of the steam used by the engine, and can be operated on one-half of 1 per cent of the steam consumed by the engine. It is manufactured by Dean Bros. Steam Pump Works, Indianapolis, Ind.



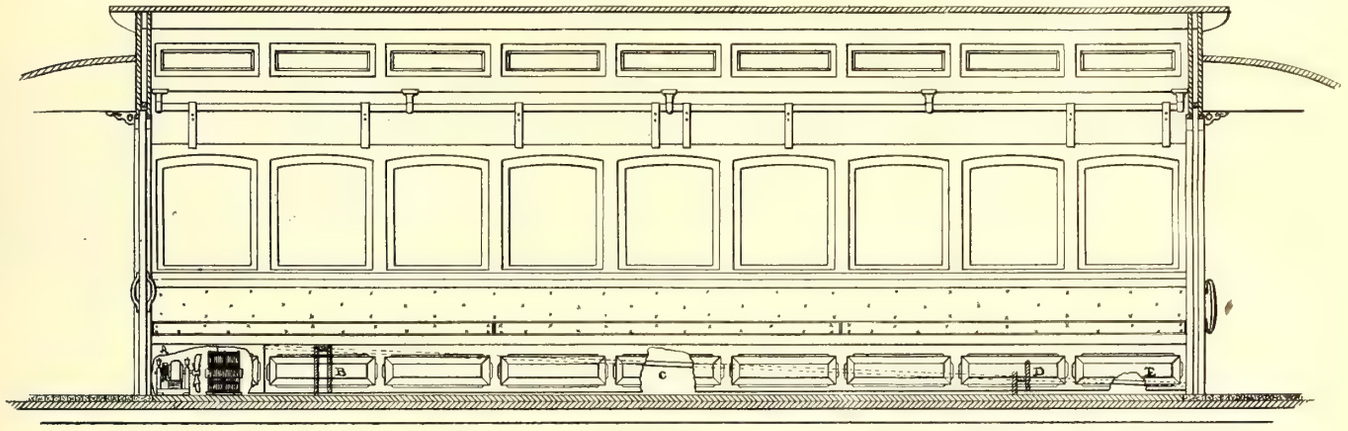
VERTICAL AIR PUMP AND JET CONDENSER

The Société Générale des Tramways Electriques en Espagne, which was formed last year in Madrid, Spain, with a capital of f.10,000,000, is about to increase its capital to f.20,000,000 for the purpose of building new electric tramways in various parts of the country. This company controls all the tramway lines in Madrid, most of which are still run by horse power. This increase of capital is for the sole purpose of converting the entire horse car system into electric traction.

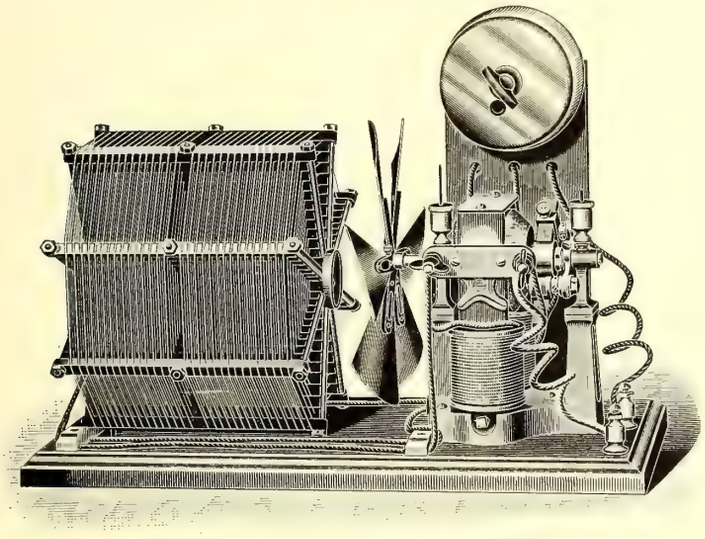
An Improved Electric Car Heater

The problem of sanitation and economy in the heating of electric cars is one requiring much consideration. A heater that makes use of every heat unit employed, keeps the air in circulation, and uses only pure air from the outside of the car would seem to be most desirable. The cuts accompanying this article illustrate a system which is claimed to fulfill these conditions without its being difficult to install or encroaching upon the passenger space of the car.

The heater consists of a heating web woven with special resistance wire, by means of which the heat is generated. One heater is sufficient for an electric car with an inside length of 25 ft., but two may be employed if considered an advantage for any particular reason. Behind the heating web is placed a fan motor of special construction, which, with an ingenious arrangement for forcing the air equally to all parts of the car completes the entire heating apparatus. The heating web and motor are enclosed in a case, which can be removed at will from the car, or they may be permanently located in the car. In either case they occupy but small space, and can be placed under the seat at the end of the car, or under the floor of the car itself. The heat issues at the floor, and at all parts equally, thus heating a part of the car not affected by a stationary heater. In connection with the heater a special switch is used, constructed so as to admit of the regulation of the heat. The accompanying illustration gives an idea of the heater and motor as they appear before being enclosed. In operation, no parts whatever are visible to the occupant of the car, and it is claimed that no parts can be over-heated.



SECTION OF CAR, SHOWING HEATER



ELECTRIC FAN AND HEATING WEB

The fresh air from the outside is heated directly, and, by means of the fan, is forced into the car, thus putting the entire body of air in circulation, the heat being evenly distributed.

The manner in which the air enters the interior is shown in the section given of a car equipped with this apparatus. The riser under the seat does not quite reach the floor, thus leaving a narrow slit the entire length of the seat for the admission into the car of the heated air. A longitudinal partition gradually diminishes the size of the air chamber under the seat, so that although the pressure falls off as we recede from the fan, an even flow throughout the entire length of the slit is secured. In the drawing this partition may be seen where the panel is cut away at *C*, the dotted line showing how it slopes from one end to the other.

It is claimed that this system has many advantages over the stationary heaters commonly used. Among them may be mentioned the impossibility of over-heating the woodwork, cushions, etc., and the greater rapidity with which a car can be heated. The heater itself does not rise to a very high temperature, as the continual current of air being warmed prevents its retaining the heat. No metal whatever, appears on the surface of the car riser, or at any point where it could be seen or felt by persons in the car.

The system above described is being brought out by Bay State Electric Heat & Light Company, of Boston, Mass., and is called the Bay State heater. The apparatus is being tested by some large companies, among them the Lynn & Boston Railroad Company, and it is claimed that the results bear out fully the theoretical prophecies.

The Spiral Nut-Lock

The novel nut-lock illustrated on this page is being brought to the attention of railway men throughout the country. S. A. Crone, formerly master car builder for the New York Central Railroad and a past president of the Master Car Builders' Association, has been made selling agent for the Spiral Nut-Lock Company, which is placing the device on the market, and he has succeeded in interesting many of the large roads in what he claims to be the simplest, cheapest and most effective nut-lock ever produced. Since its introduction less than a year ago numerous tests have been made on tracks, locomotives, steam drills and hammers, and other places where the vibration caused all formerly used locking devices to fail, and in every case the company reports satisfactory operation.

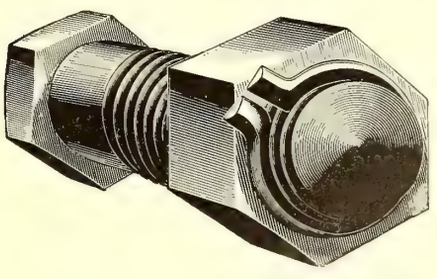


FIG. 1.—BOLT WITH NUT LOCK

FIG. 2.—NUT LOCK

The nut-lock is made of crucible steel triangular wire, bent cold and tempered. It is made a little smaller than the diameter of the bolt, but after it has been started on the end of the bolt any leverage applied betwen the projecting ends, such as a screwdriver or flat key, will spring the lock open enough to allow of its being easily screwed up against the nut. The curve of the spiral changes as shown in the cut, and in order that the entire circumference of the thread may be gripped effectively, the nut-lock must be put on "right side out." This is made very simple by having the end which is first to engage the thread flattened, as shown by the arrow in Fig. 2, so that the workmen can tell at a glance which way to apply it. The removal is as simple as placing it in position, and should it be rusted on a blow from a hammer will break it off. The

price is claimed to be lower than that of jam-nuts of the same size, and a shorter bolt can be used than would be necessary with any kind of split washer, jam-nut, etc.

Perhaps the reason for its tenacious grip on the thread of the bolt is due to the fact that the nut only touches the spiral for about one-third of its length, thus reducing the power which it would have to turn the nut-lock.

Opening of a New Electric Railway in Brazil

The first section of the electric tramway system of the Sao Paulo Electric Railway, Light & Power Company, Ltd., which was described in the STREET RAILWAY JOURNAL for July, 1899, was put in operation last May. As will be remembered, this line is being built by American engineers and American capital, and the construction of the road was carried on largely under the personal direction of F. S. Pearson, of New York, who is largely interested in the enterprise.

The daily papers published in Sao Paulo immediately after the opening of the first section of the line, have just arrived in this country, and announce the great interest taken in the electric cars, and the enthusiasm of the inhabitants over the inauguration of the

FIRST CAR ON BOM RETIRO LINE

electric system. The following account of the opening of the line is taken from one of the leading Sao Paulo papers.

"In the hurried lines of a notice which suffers from the haste with which it is written it is impossible to give the exact measure of the intensity of joy and satisfaction which was visible in the looks of all on account of the realization of so notable an improvement. The enthusiasm of the people crowding on the streets through which the vehicles ran is indescribable, and when the cars were placed at the orders of the public after the inauguration, one can hardly imagine the extent of the invasion that took place. Everybody made efforts to obtain seats in the cars, but in spite of the natural confusion of such occasions, not the slightest incident took place that might sound a discordant note in the great festival, in which the people took part with the highest demonstration of joy.

"Having given in the beginning this salient point, we will describe the inauguration of the great improvement according to the notes we were able to take.

"As had been arranged, several persons invited had repaired at 12 o'clock to the building in Rua Direita, where is the office of the Sao Paulo Railway, Light & Power Company, Ltd., and the store of James Mitchell & Company, to set out together from there to the company's power house, where the president of the State was to start the principal engine, while the other guests were at the car house at Alamedo Barae de Limeira, at 2 o'clock, the hour for the inauguration. At the company's power house at the Rue Monsenor Andrade, where the guests arrived at 1 p. m., there were Dr. Oliveira Ribeiro, chief of police, accompanied by his aide-de-camp, Captain Ozorio, and Dr. Cerqueira Cezar, president of the Senate, besides Dr. Campos Porto, representing the Platea, and Sr. Anibal Machado, of the Imperio, and other engineers of the company. Afterwards there arrrived Dr. Rodrigues Alves, president of the State, his aid-de-camp, Captain Jayme Marcondes, Dr. Prudente de Moraes, accompanied by his son, Antonio Prudente de Moraes.

"At twenty-five minutes past 1 Dr. Roiz Alves started the big engine by moving the throttle valve; a few moments afterward Drs. Roiz Alves, Prudente de Moraes, Domingos de Moraes, Bento Bueno, Francisco Malta, Cerqueira Cezar and Mrs. Burchard made the several connections of the current producing and safety apparatus, transmitting the electric energy to the cables and supplying light, which appeared in all the lamps of the building. After a short examination of all the machinery and the great boilers, the guests started for the car house at the Alameda Barao De Limeira, where they arrived at 2 o'clock.

"There were present Dr. Albuquerque Luis, president of the Camaraete, representatives of the prefecture, and many other deputies, senators, and a great host of persons, whose names it was impossible to take down. After a rapid visit to the storehouse, the guests took their places in the six cars, which were in front of the building. The cars were decorated with flags and festooned, the Brazilian, British and American flags being seen at the top.

OPENING OF LINE

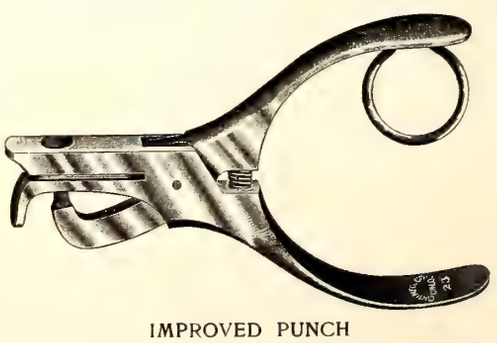
"At ten minutes past two, when the National, British and American hymns were being played, the cars started, making the inaugural trip along Alameda de Limeira, etc. Along the whole line the crowd of people was immense, greeting the electric company, and the windows were filled with families looking on. From Largo Sao Bento all the cars returned as far as the temporary terminal point at the end of the Alameda Barao de Limeira, where they again returned to the car house. There a profuse and liberal lunch was served, 200 persons sitting down at the table, the service being done by the Confeitaria Castelloes. During the lunch the band played several pieces.

"On serving the champagne Dr. Carlos de Campos arose, and in the name of the company greeted the President of the State and Municipal Prefect, as representing the people. Dr. Antonio Prado, referring to the great improvement, introduced in this capital, greeted the Electric Tramway Company. Mr. Brown, superintendent, returning thanks for the toast which had been proposed, drank to the prosperity of the State of Sao Paulo and the agrandisement of the Brazilian country.

"The toast of honor was proposed by Dr. Roiz Alves to Dr. Campos Salles, president of the Republic, this toast being enthusiastically responded to, the band of the police brigade playing the National Hymn. During the remainder of the afternoon the electric cars were offered gratuitously to the public, making several trips between Largo Sao Bento and Alameda Barao de Limeira, carrying a considerable number of passengers, many hanging on at the sides. At 7 p. m. the traffic was suspended, to begin today the regular trips."

An Improved Ticket Punch

The form of punch illustrated herewith is intended to be of service in all cases where a first-class article is desired. It has a long reach, thus facilitating its use on roads which have long transfer tickets, and the open sight permits the conductor to operate it



IMPROVED PUNCH

quickly and accurately. The dies are of hardened tempered steel, which gives good results after long wear. This punch is one of twenty-five styles made by the Cincinnati Manufacturing Company, Cincinnati, Ohio. The design is new, but wherever introduced has given satisfaction.

The New Plant of the Falk Company

Most readers of this paper will remember the announcement that appeared in the JOURNAL considerably over a year ago, stating that the works of the Falk Company, at Milwaukee had been completely destroyed by fire. The company immediately began the erection of a new plant, work upon which was retarded considerably by the difficulty in securing material. The new works are located in the Menominee Valley at the foot of Thirtieth Street, some twenty minutes' ride from the heart of the city. Beside the office building, there are three large separate buildings, the foundry, machine shops, blacksmith shop and power house.

The office is a model of convenience, comfort and elegance; the entire interior being built of hard wood, and furnished throughout, desks, chairs, tables, etc., etc., of golden oak. It is equipped with a fire proof vault, toilet and wash rooms, a shower bath, private rooms for the various members of the company, and a directors' room.

The first building next the office is the open hearth steel foundry. It is of steel and brick, the same construction being used for all the buildings. The foundry is 100 ft. x 200 ft., one end being boarded up temporarily, allowing for extension at any time. The foundry is equipped in every department with the most modern apparatus, including a Wellman-Seaver tilting furnace, which has many advantages over the old style of stationary furnaces. Steel is made by what is known as the acid process, which produces castings which are perfect as regards finish, free from blow holes and other defects. Two, 25-ton with 5-ton auxiliary hoist, each, Pawling & Harnischfeger cranes are in use. The foundry has a capacity of about 50 tons per day, and is equipped to handle castings from 30 lbs. to 35,000 lbs. each. The cleaning apparatus is of the most improved kind, and designed by members of the company. The Falk Company takes particular pride in its ability to turn out castings which have troubled other founders, and has already gained an enviable reputation for this class of work. The company makes all its own gear castings, of which it is a large manufacturer. This gives the advantage of being able to secure uniform material and that best suited to this particular line of work. These gears are all made with specially constructed flasks, as well as other apparatus; the methods employed are such as to produce castings absolutely free from blow holes and true to pattern. Since the foundry was started not a single casting has been discarded on account of developing blow holes, which indicates the uniform quality of the Falk gears.

A specialty is also made of castings for steam railways, castings for engine and cars, and knuckles for coupler repairs, the latter being produced by the thousands.

All iron and steel used in the various departments is analyzed in the company's own laboratory, fitted up in one corner of the foundry. This is all bought on a specified analysis, and if any is not found strictly up to specifications it is rejected. A competent chemist devotes his entire time to this work.

The machine shop is also 100 ft. x 200 ft. It has every modern appliance for the manufacture of gears and pinions and special work. All machines are driven by motors, either directly connected or bolted, so that one motor drives a group of two to four machines. The latter ones are placed on an overhead platform, running the entire length of the shop. All are driven from a generator in the power house. An interesting corner under this roof is that of the inspection department. Here every gear and pinion passes a rigid test for errors in dimension or flaws in material, with the result that the Falk Company has no shipments returned from dissatisfied customers.

VIEWS IN THE WORKS OF THE FALK CO.

Back of the machine shop is a large platform for laying out special work; here also are the sand and stock sheds and pattern building. Beyond the machine shop is the building containing the blacksmith shop and power station. Here are made all pinion forgings, used by the company; these are made from open hearth steel billets, of high carbon, which is found to be the very best grade of material suitable for this work. The pinions are made from individual forgings, which are hammered thoroughly to produce a very close grain and hard metal.

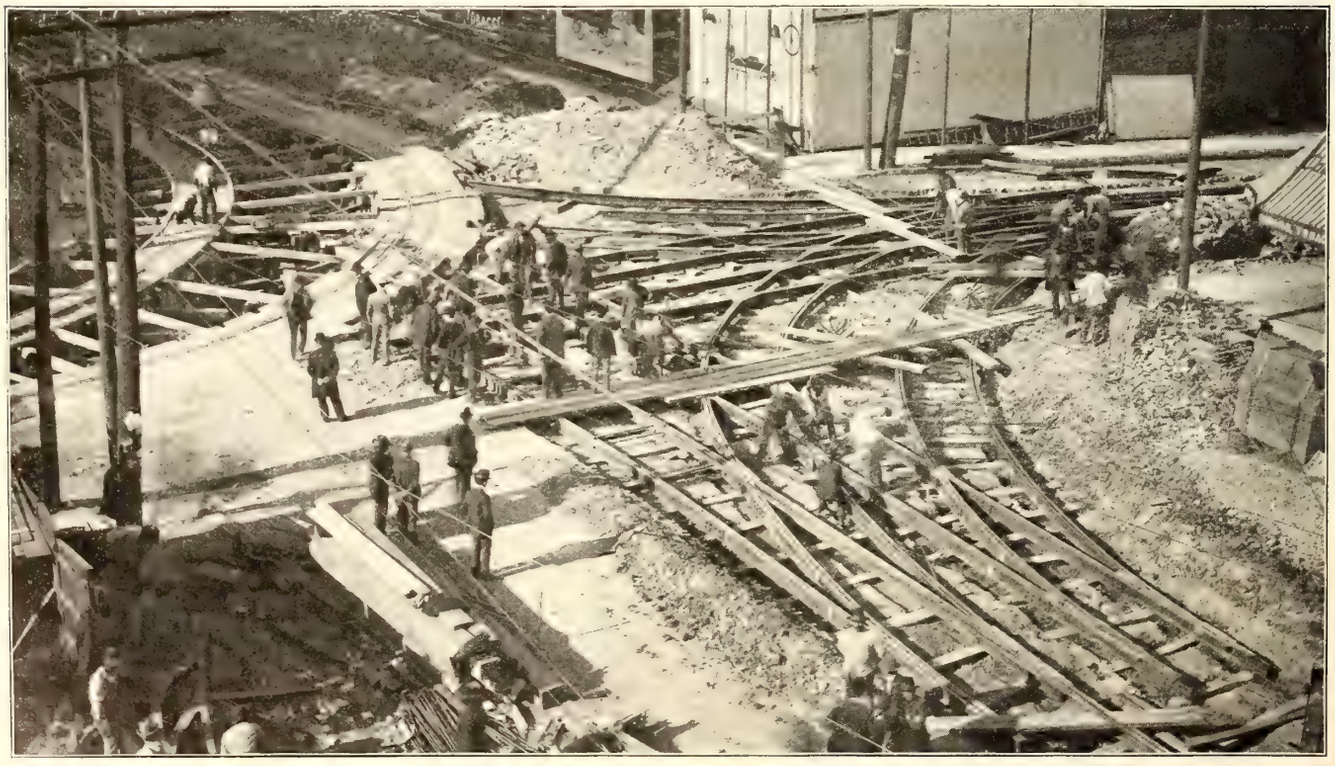
The engine room, in one end of this building, has a 250-hp horizontal Allis Corliss engine, belted to a 220-volt 150-kw. General Electric generator. The switch board has Cutter circuit breakers, and Weston instruments. The boiler plant consists of three 80-hp tubular boilers. The shops are heated with hot air.

The factory's railroad facilities could hardly be improved upon, as switches from the C. M. & St. P. R. R. run through each shop building, and bring material to the yard outside.

The Falk Company was organized in 1894, under the name of The Falk Manufacturing Company, and introduced upon the market the cast-welded rail joint, upon which the company owns all the original letters-patent, and which it is at present vigorously defending against all infringers. When this joint was first brought out, it was accepted with a great deal of hesitancy by street railway men and engineers, but actual practice has long since demonstrated its success, and it is now standard construction on all roads throughout the world. The Falk Company has welded nearly 1,000,000 joints.

At the suggestion of railway men, for whom the company was already doing work, the manufacture of special work was taken up, and this department has grown until the Falk Company is now

CONSTRUCTION WORK AT KANSAS CITY



COMPLICATED CURVE AT KANSAS CITY

one of the largest special work manufacturers in the country.

In commencing the manufacture of special work, the company secured the services of a competent corps of engineers, and began the construction and complete equipment of electric street railways. The company has an excellent organization for this class of work, and takes a great deal of pleasure in pointing to such work as that done for the Citizens' Traction Company, Oshkosh, Wis.; the building of the Interurban Railway between Oshkosh and Neenah, Wis.; the reconstruction of the lines at Davenport, Ia., Decatur, Ill., and Kansas City, Mo. Of this latter work, upon which the company has been employed for the last two seasons, it is especially proud. Here the company has recently accomplished one of the most difficult engineering feats met with in street railway construction. The problem was to change the double cable track on Grand Avenue between Eighth and Ninth Streets, which was one compound curve, extending the entire block, to simple curves at Eighth and Ninth Street corners with straight track connecting. This necessitated moving both tracks bodily, several feet to one side of the old location. The operation shortened the track to the extent that the cable itself had to be shortened twice during the progress of the work. The headway between trains at this point does not exceed two or three minutes, which made the work extremely difficult and dangerous. Thus far there has not been the slightest obstruction to traffic, nor a single accident, and the work is practically finished, notwithstanding the fact that the feat was considered by even the street railway company itself, as practically impossible.

Considering the short time it has been in existence the Falk Company has had a remarkable growth. This is due to the honesty of its work and products, coupled with courteous treatment towards all of its customers, who can be found in almost every street railway town, not only in America, but of Europe as well. Its foreign shipments number many tons of material a month, and its cast-welding outfits can be found in many places on the continent.

The officers of the company are Herman W. Falk, president; Otto H. Falk, vice-president; E. A. Wurster, secretary and treasurer; Clement C. Smith, second vice-president; Adolph Quentin, third vice-president; C. L. Jones, assistant secretary; W. Frank Carr, chief engineer.

WORKS OF THE FALK CO.

Electric Fans

As the summer is approaching the question of motor fans becomes again of importance, and that this is of interest to electric railway companies as well as to companies distributing electric power for miscellaneous purposes is shown by the fact that a number of fan manufacturers build fans for 500-volt circuits. The desk fan illustrated herewith is from the factory of D. L. Bates & Brother, located at Dayton, Ohio. This concern is not new in the business, having been engaged in the manufacture of electric fans for the last nine years, and it reports an increasing demand for its product. While the types of fans are somewhat familiar, various improvements have been made both in mechanical construction and in the efficiency of the motors. The fans are finished in nickel, oxidized copper, polished brass and Japan.

Freight Car on Maximum-Traction Trucks

The accompanying illustration represents a novelty which may be of interest to street railway men and others. It is nothing less than a 30-ft. freight car, mounted on maximum traction trucks. It was built by the J. G. Brill Company for the Winston Road in North Carolina. At one end are four posts which carry the trolley pole. Both ends are fitted with dashers and brake wheels. The car is of the regular steam gondola type, with truss rods and needle beams, stake pockets and stakes running along the sides. The body was made as low as practicable, and is 7 ft., 6 ins. wide at the sills. There are two G. E. 58 motors. The trucks have a 4-ft. wheel base, the wheels being 33 ins. in diameter, with 3-in. tread and 5/8-in. flange. The gage is standard.

ELECTRIC FREIGHT CAR

CURRENT NEWS

Syracuse Mutual Benefit Association

The Mutual Benefit Association of the Syracuse Rapid Transit Company, is one of the strongest organizations of its kind in the country, and has a membership of 250, out of about 350 employees. A large number of those who are not members now are ineligible on account of age. The organization has rooms fitted up in the Gridley Block, and they occupy nearly the entire top floor. The association is a combined pleasure and benefit organization, and pays $1 a day during a member's sickness, and $150 when a member dies. The rooms of the company are laid out after the style of other similar organizations, and are supplied with billiard tables, etc., for the amusement of members. On May 14 the membership was increased by the initiation of about 100 new members. On this occasion the board of trustees served a repast, and an enjoyable evening was spent. From present indications the association will soon have a very handsome reserve fund.

Bridgeport Traction Company's Employees' Association

The employees of the Bridgeport Traction Company organized the Bridgeport Traction Company's Employees' Association on June 22. The organization has a membership of 50, and it is expected that this will be increased to 150. The new organization is planned after, and will follow the lines of the Mutual Benefit Association, of the Syracuse Rapid Transit Company. It will pay both sick and death benefits, and will shortly fit up club rooms where members will be entertained. The officers of the organization are: President, Thomas Burke; vice-president, William Killeen; financial secretary, Robert McCullough; recording secretary, Edward McCormack; treasurer, Howard Miller. A committee on by-laws was appointed as follows: Harry Daunt, chairman; Frank Riley, John Lynch, Henry Bain and Charles Neadles.

New Air Cars in New York

The Metropolitan Street Railway Company has just received from the Compressed Air Company the first of the perfected type of air motors intended for service on its Twenty-eighth and Twenty-ninth Street crosstown lines. The present old style air motors will be withdrawn from service on Twenty-eighth and Twenty-ninth Streets, and horse cars temporarily substituted so that the present car bodies can be fitted with the improved type of air motors. Meanwhile the line is being relaid with heavy steel rails. The new motors are the first of the 125 motors the Compressed Air Company is under contract to build for the Metropolitan. The motors are of improved and perfected design, obviating objectionable features and of increased power and economy.

Transfers in Baltimore

The United Railways & Electric Company, of Baltimore, Md., will, after July 1, give transfers on all its lines. Some time ago the transfer system was partly abolished on account of the abuse it received from the traveling public, but it is thought that under the new system the passengers and railway company will both be satisfied. Transfers will be given at all points of intersection except those points at which the passenger could take a car returning in the same general direction from which he had come or those which mark the terminus of one of the various lines.

Suits Against the Chicago Elevated Railroads

James R. Walker and the executors of the will of W. D. Walker have begun suit in the Superior Court against the Union Elevated Railroad Company for $250,000, and against the Union Consolidated Railway Company and the Union Elevated Railroad Company for $150,000, as damages. L. Z. Leiter is plaintiff in a suit against the Union Elevated Railroad Company and the Union Consolidated Elevated Railway Company for $1,000,000, and in one against the Union Elevated Railroad Company and the Northwestern Railroad Company for $100,000 as damages. The Union Elevated Railroad Company is also made defendant in suits begun by Thomas Murdock and Byron L. Smith and Ezra J. Warner, trustees under the will of Simon Reid, who asks damages in the sum of $150,000. The damage to the property is caused, it is alleged, by the construction and operation of the roads in the vicinity of the buildings owned by the plaintiffs. The plaintiffs and the amount of damages sought in still other suits are James Oliver for $150,000, against the Union Elevated and the Union Consolidated Railroad companies, and William C. Lebenstine, for $250,000 and $50,000, against the Union Elevated and the Northwestern Elevated Railroad companies.

Organization of Employees' Club at Camden

On Monday evening, June 11, an interesting gathering of the employees of the Camden & Suburban Railway Company of Camden, N. J., was held at the new car house, Newton Avenue, near City Hall, at which time a room was presented by the management of the company for the use of the employees as a recreation and reading room. The room has been provided with conveniences, nicely furnished with chairs, tables, black board and hat racks. A large number of popular magazines and technical journals have been subscribed for. The room was presented by Walter E. Harrington, general manager, and accepted on behalf of the employees by Samuel Holmes, one of the company's oldest employees. In presenting the room and describing among several of the purposes for which the room would be used, the following novel plan was proposed: To set aside one night in each month to be called "discussion night," at which time a subject would be selected of interest to the employees, relating to some subject in connection with the operation of the road; a committee chosen among the men to investigate, test and otherwise make an elaborate report to be read at the following meeting, and to be open for discussion by the employees and others interested; the full proceedings of the meeting to be taken stenographically and edited, in order to be kept on file. In connection with the above the social side is to be provided for. The employees voted a resolution of thanks, to be presented to the company, and a committee was appointed by the employees, of which B. Bibighaus was chairman.

The subject of "brakes" has been selected for the next meeting night of the club, and a committee of five motormen has been delegated to make tests and determine the time and distance it will take to stop cars of different weights and sizes. The subject for the evening in August is "How to Handle Controllers."

It is the intention of the club to cover, not only matters of electrical interests, but also general operating problems. The employees have taken an enthusiastic interest in this plan, and the committee appointed to investigate brakes has already had a meeting.

PERSONAL MENTION

MR. W. D. SARGENT, general manager of the Sargent Company, Chicago, returned from Europe Saturday last, the 23d, after a two months' trip.

MR. CHARLES P. TOLMAN, of the Christensen Engineering Company, of New York, is in Manchester, N. H., superintending the work of equipping the large cars of the Manchester Street Railway, with air brakes.

MR. CHARLES A. WORTS, of Oswego, has been elected general manager of the Rome Street Railway Company, of Rome, N. Y., to succeed Mr. W. P. Brown, who resigned to accept a position as general manager of a steam railroad.

MR. PETER KLING has resigned his position as general manager of the St. Louis Car Company, to accept a similar position with the John Stephenson Company in New York. It is not known who will succeed Mr. Kling, as Mr. Kobusch, president of the company, is out of the city.

MR. ALEX. WILSON, who recently left the employ of the Hamilton, Grimsby & Beamsville Railway to become chief clerk of the Hamilton Street Railway Company, of Hamilton, Ont., was presented with a gold mounted silk umbrella, suitably inscribed, in recognition of the company's appreciation of his six years of faithful service on the Hamilton, Grimsby & Beamsville Electric Railway. The presentation took place in the company's office, Vice-President W. J. Harris making the presentation speech.

MR. GORDON ABBOTT has been elected to fill the vacancy caused by the death of Mr. Amos Breed, as president of the Massachusetts Electric Companies. Mr. Abbott is also president of the Tacoma Railway & Light Company, of Tacoma, Wash.

MR. S. W. CHILDS, of the J. G. White Company, of New York, has just returned from Perth, Australia, where he has been for the past eighteen months superintending the electrical equipment of the Perth Tramways. Mr. Childs made a host of friends during his stay in Australia, and was given a rousing reception previous to his return home. A farewell banquet was tendered in his honor at the Grosvenor Hotel, and it was attended by the merchants of the city, councillors and officers of the city, and contractors and employees of the Electric Tramways Company. During the toast, "The Guest of the Evening," Mr. Childs was highly complimented for his good work, and regret was expressed at his retirement from the service. Mr. Childs was the recipient of two purses of sovereigns, one from the merchants, contractors and officers of the Council, and one from the employees of the Tramway Company. Mr. H. J. Somerset succeeds Mr. Childs.

NEWS NOTES

MIDDLETOWN, CONN.—The offices of the Middletown Street Railway Company were entered by burglars recently. It is not known how much the robbers secured.

BRIDGEPORT, CONN.—The Bridgeport Traction Company intends to inaugurate an express service on its line between Bridgeport and Woodmont.

HARTFORD, CONN.—The Hartford Street Railway Company has presented the Common Council with a petition for several extensions of its system. It is proposed to run a single track from the Barnard Park on Main Street through Park Street to Lafayette Street, and to lay a single track from Zion Street to Laurel, thus making a through track from Main Street through Park Street to Prospect Avenue. Another line of single track is to run from Main Street through Capen Street to its junction with Barbour Street and thence to Keney Park. Another extension is a double track from Barnard Park south through Maple and Franklin Avenues to the Wethersfield town line.

CHICAGO, ILL.—Charles L. Bonney, as counsel of the Chicago General Railway Company, has submitted to the reorganization committee a plan for the proposed reorganization of the road. He says that by continuing the receivership for about a year the assets of the company can be collected, the floating debt paid and the property returned to its stockholders.

CHICAGO, ILL.—Through the kindness of President Roach, of Chicago, the Union Traction Company, who donated the use of two electric cars, 150 women and children of St. Elizabeth's Social Settlement were given an outing from the settlement house, June 22.

CHICAGO, ILL.—Lawton C. Bonney, shareholder of the Chicago General Railway Company, has brought suit for $125,000 damages against John A. King and John H. Witbeck. The latter was for a time president of the company. The suit is based on the allegation that the defendants conspired together to injure the credit and business of the plaintiff. During May suits on notes for an aggregate of $125,000 were brought against the Bonneys, Lawton C. and Charles L. Bonney, by John H. Witbeck. These actions were on notes signed by the Bonneys, which Witbeck declared were due to him. L. C. Bonney asserts the notes had been paid by Witbeck with funds from the assets of the company. John A. King, co-defendant with Mr. Witbeck, is president of the Fort Dearborn National Bank.

NEW ORLEANS, LA.—The lower branch of the Louisiana Legislature passed an act June 26 to compel separate and equal accommodations for blacks and whites on street car lines. It is believed that the Senate will pass the measure.

BOSTON, MASS.—On June 28 Governor Crane signed the bill to compel street railway companies to vestibule their cars.

AMHERST, MASS.—Electric and steam railway interests are in conflict here. The Boston & Maine Railroad has applied for an injunction to prevent the Amherst & Sunderland Street Railway Company from continuing to cross a bridge over the Boston & Maine here.

BOSTON, MASS.—It is expected that the overhead division of the Boston Elevated Railway Company will be in operation by Jan. 1, 1901. But for delays in receiving deliveries of materials on contract the division would have been in operation Oct. 1.

RUTHERFORD, N. J.—W. C. Giles, president of the Newark & Hackensack Traction Company, swore out a warrant for the arrest of Captain Addison Ely, president of the Bergen County *Herald* Publishing Company, and Henry H. Copeland and Edward J. Luce, of the law firm of Copeland, Luce & Kipp, on June 20, on a charge of conspiring to publish a libel against the Traction Company. The libel complained of was published in the Bergen County *Herald*, and Mr. Giles already has suits pending against Captain Ely and the newspaper, in which he asks damages of $50,000.

NEWARK, N. J.—The North Jersey Street Railway Company has adopted an ingenious device to save the passengers in its open cars from the consequences of poking their heads out of the car where they are likely to get in the way of any vehicle on the other track. On the side of the cars facing the opposite track the company is putting in, above the side-bar and on a level with the passengers' heads, a light wire grating about 18 ins. wide. To get his head outside of this a passenger must either lie down on the floor and crawl underneath the grating or stand on the seat and lean out near the roof. The screen is transferable to either side.

ROCHESTER, N. Y.—The employees of the Rochester Railway Company held their first annual outing on June 25, at the Island Cottage, Buck Pond, on the Manitou Beach Railway. It is estimated that 200 employees were able to be at the picnic. Athletic sports were indulged in, and a game of baseball was played. A number of officials of the company were at the picnic. Among them were Treasurer Moorehouse, General Manager Nicholl and Superintendent Hicks.

SYRACUSE, N. Y.—The Syracuse Rapid Transit Company proposes to equip its cars with illuminated destination signs in the near future.

NEW YORK, N. Y.—The proposed hearing on the application of the Metropolitan Street Railway Company for a street-car franchise in Elm Street, before a joint committee of the Municipal Assembly, has been postponed indefinitely.

BROOKLYN, N. Y.—Two young women were struck by a car of the Brooklyn Rapid Transit Company on the Coney Island Creek Bridge at 1:30 o'clock on June 21 and instantly killed.

NEW YORK, N. Y.—Justice Bischoff, in the Supreme Court, by consent of the lawyers, adjourned until July 9 the arguments on the application of the Manhattan Railway Company to continue the injunction to restrain the Park Board from interfering with its elevated structure in Battery Park.

SYRACUSE, N. Y.—Attorney-General Davies has reserved decision after listening to arguments on an application of Samuel Ferguson for the beginning of an action to annul the franchises of the Syracuse & Oneida Lake Electric Railway Company, made on the grounds that it has failed to construct its road within a year after having obtained the required consent from the authorities of the towns through which it proposes to pass.

UTICA, N. Y.—The Utica Belt Line Street Railroad Company has voluntarily increased the wages of its employees. The following bulletin, posted on the bulletin board at the depot June 25, announcing the change: "Utica, June 25.—Commencing July 1, 1900, conductors and motormen during the first year of their employment will receive 14 cents an hour; between one and five years, 15 cents an hour, and over five years 16 cents an hour. Conductors and motormen who shall have been continuously in the employ of the company for five years will be entitled to wear two service stripes on the left coat sleeve of the regular uniform, which should now be obtained, the conductors' stripe gold and the motormen's silver, and one additional stripe to be added for every additional five years. John W. Boyle, president." There are just 127 men who will be affected by the order, which is the second one announcing an increase of wages within a little over a year. The present wage rate is 13½ cents an hour to conductors and motormen during the first year of their employment. The new order increases it to 14 cents, an increase of half a cent an hour. Conductors and motormen who have been in the service of the road over a year are now earning 14 cents an hour. There is a new arrangement under the new order which will have a tendency to make the employees desire to continue in the employ of the road permanently. Employees who have been on the road over one year will, after July 1, receive 15 cents an hour, and those who have five years to their credit will receive 16 cents an hour.

TOLEDO, OHIO.—The Toledo Traction has just prepared for gratuitous distribution a very neat folder on Toledo. On one side of the folder is a bird's-eye view of the city, showing the principal lines of the street car system, various points of interest in and about the city, Lake Erie Park and Casino, and lastly a diagram and bird's-eye view of the Ohio Centennial grounds. On the reverse side is a brief history of Toledo, something about the location and industries, its population and its wealth, considerable data regarding the street car system, and lastly a history of the Ohio Centennial to date.

SPRINGFIELD, OHIO.—The suit of S. L. Nelson against the American Railways Company, in which the plaintiff asks for $70,000 commissions for the negotiation of the deal by which the company purchased certain street railway properties in Dayton, has been removed to the Federal Courts, at the request of the defendant.

COLUMBUS, OHIO.—A resolution was adopted by the Board of Public Works a few days ago, declaring void the franchises held by the Columbus Railway Company as successor to the Columbus & Westerville Electric Railway Company. The original franchises covering a number of important streets were granted in 1894, and, although the time limit has been repeatedly extended, the roads were never built.

HARRISBURG, PA.—Writs of quo warranto were issued June 22 by Judge Simonton, at the instance of Attorney-General John P. Elkin, against the following street railway companies: Washington & Belle Vernon, Belle Vernon & Fayette Street, Fayette County & Belle Vernon and North Belle Vernon, requiring them to show cause by what authority they claim to have and use the rights and processes, privileges and franchises of such corporations. These companies were chartered by the State, Dec. 12, 1899, but since that period no railway has been constructed or operated upon any part of the routes mentioned in their charters, by reason of which the rights of these companies to exist as corporations have become forfeited to the commonwealth.

PITTSBURGH, PA.—On June 26, George W. Stern, of New York, filed two suits in equity in the United States Circuit Court against the directors of the Consolidated Traction Company and the Union Traction Company, consisting of C. L. Magee, Joshua Rhodes, B. F. Jones, T. H. Given, George I. Whitney and John A. Bell, of Pittsburgh. Stern prays for an accounting of dividends paid in excess of earnings of the company as dividends on preferred stock, and that they be particularly ordered to pay the treasurer $360,000 paid out after notice of dividend No. 6; that defendants be ordered to repay the Consolidated Traction Company amounts unlawfully received by them, purporting to be paid as dividends, and also that a receiver be appointed. Stern claims to be a holder of 500 shares of common stock. The case will come up in the November term of court.

PITTSBURGH, PA.—The Consolidated Traction Company has awarded a contract for 42 miles of feeder cables. The new cable will be used largely to supply current for the operation of several extensions now under construction.

KENOSHA, WIS.—At a meeting of the City Council, June 25, the Haynes-Clausen Street Railway franchise was passed to its final reading. The franchise carries a resolution attached demanding that the promoters file a satisfactory bond within seven days with the Northwestern Loan & Trust Company, of Kenosha, indemnifying the property owners on three paved streets for 7 ft. of paving. The franchise calls for a through and local line, which will form the completion of the electric system between Milwaukee and Chicago, when the line shall have been extended through to Waukegan. By the conditions of the franchise they are bound by $60,000 more for the performance of their contract. The franchise promoters are P. F. Haynes and G. L. Clausen, of Chicago.

MILWAUKEE, WIS.—The Wisconsin Supreme Court has denied the application of the Milwaukee Electric Railway & Light Company for permission to build under the franchise granted by the Mayor and City Council last January. This decision will keep the original injunction granted by Judge Ludwig in force, and will prevent the company from proceeding with the construction of any of the lines until a verdict is rendered by the Supreme Court.

TORONTO, ONT.—The employees of the Toronto Street Railway Company have formed a new court of the Independent Order of Foresters and named it the "Electric." The initial membership of the organization is eighty members.

MONTREAL, QUEBEC.—Considerable comment is said to have been caused in Montreal municipal circles by the application from the Montreal Terminal Railway (the old Belt Line) to continue its service through the city. The application was referred to the road committee of the City Council, and will probably be resisted by the Electric Street Railway Company on the ground, frequently urged heretofore, that the granting of such permission would be a violation of the contract between the company and the city. However, legal opinions have been given to the effect that under its contract the street railway company has no monopoly of the city streets. It appears that if the Terminal Company obtains the desired permission it will construct one or two electric car lines from one end of the city of Montreal to the other, connecting with its suburban system in the east end of the island. Some time ago this company endeavored to make arrangements with the Street Railway Company to run Belt Line cars to the center of the city or to lease special cars of its own connecting the Belt Line suburban service with the center of the city. This being refused, the Terminal Company now seeks to build city lines of its own, as it is empowered to do under its charter from the Dominion Parliament.

MONTREAL, QUEBEC.—A most extraordinary thing occurred in the Canadian Senate recently, almost without a precedent. The Buffalo Railway Company's bill, which was framed to enable it to absorb all the electric railway lines between Buffalo and the mouth of the Niagara River on both sides of the line, had passed the railway committee of the House of Commons, received its three readings and also received the assent of the Commons, was sent up to the railway committee of the Senate. It was passed by that body and received its first and second reading in the Senate, which is usually tantamount to a bill being passed, but, on its coming up for third reading, which is usually only a formality, it was thrown out. The company was incorporated in New York, and this action affects the Cataract Power Company, Hamilton Electric Street Railway, the Hamilton & Dundas Electric Company, Hamilton, Grimsby & Beamsville Electric Railway, Hamilton Radial Electric Railway, Galt, Hespeler & Preston Electric Railway, Niagara Falls Park & River Railway, Buffalo & Niagara Falls Electric Railway, Niagara Gorge Electric Railway, Buffalo, Tonawanda & Niagara Falls Electric Railway, Buffalo & Lockport Electric Railway, Niagara Falls & Suspension Bridge Railway, Niagara Falls, Whirlpool & Northern Railway and several others, proposed, building or being extended.

CONSTRUCTION NOTES

PASADENA, CAL.—The board of directors of the Pasadena & Mt. Lowe Railway Company have called a meeting of its stockholders for Aug. 2, to vote upon the questions of increasing the capital stock from $400,000 to $600,000 and increasing the bonded indebtedness from $375,000 to $500,000 by a new issue of 500 4 per cent $1000 thirty-year gold coupon bonds, which are to be used in redeeming the present outstanding bonds and for betterments, extensions and re-equipment of the line.

HARTFORD, CONN.—T. C. Perkins, of Hartford, has made application to the Selectmen of Agawam for the construction of an electric railway between Springfield and the Connecticut State line. Mr. Perkins' petition calls for two locations, both beginning at the State line and ending at what is called the South End bridge at Springfield. One of these, however, goes around through the center of the town of Agawam, and the other goes up along the river road. The company prefers to have the latter granted, but will take the former if the people of the town prefer. It is the intention of the promoters of the new road to run a fast line between Hartford and Springfield, and they hope to make the trip in an hour and a half.

WABASH, IND.—Joseph T. McNary, general manager of the Logansport, Rochester & Northern Traction Company, which is to build a trolley line 101 miles in length, from Logansport to Kendallville, says work will commence on the grade of the road at Logansport July 4. The money for the construction work has all been provided, and but for the illness of the civil engineer in charge of the work operations would have commenced six weeks ago. One section of the road will be in operation by fall.

KOKOMO, IND.—It is said that a company, to be known as the Kokomo, Wabash & Lake Manitou Railway Company, is to be incorporated shortly. The company is being organized to construct an electric railway from Kokomo to Rochester via Greentown, Converse, Wabash, Roann and Akron. The right of way has been obtained along the entire route, and negotiations are now on for financing the road. Franchises have been granted in all the towns on the line, and the promoters are reported to have said that the enterprise is certain to go. The road will be about 60 miles long and traverse a populous and wealthy region.

FT. WAYNE, IND.—The Ft. Wayne & Butler Railway Company has been incorporated, with a capital stock of $50,000, to construct an electric railway from Ft. Wayne to Butler, a distance of about 40 miles. The directors of the company are Robert H. Carnahan, B. Paul Mossman, Robert Millard, William H. Olds, Charles W. Orr, Van B. Perrin and Frank L. Smick.

DAVENPORT, IA.—The Tri-City Railway Company is having a part of its system double tracked in the vicinity of Warren Street. B. F. Nickerson, of the Falk Company, of Milwaukee, Wis., has charge of the work. It is expected that the job will be completed in about a month.

AUGUSTA, MAINE.—The Gardiner & South Gardiner Electric Railway Company has filed a petition with the Railroad Commission for a location. It is proposed to connect the city of Gardiner with the village of South Gardiner. The road will form one of the connecting links in the projected system between Augusta and Portland.

SEDALIA, MO.—The receivers of the Sedalia Electric & Railway Company contemplate making a number of improvements in the street railway system. The power house on East Broadway is to be enlarged, and a new car house is to be built on East Ninth Street. The latter will be 120 ft. x 50 ft. The installation of additional power-house machinery is contemplated, and several new cars are to be purchased. The old cars are to be overhauled and refitted.

ST. LOUIS, MO.—The Wellston, Creve Couer & St. Charles Railroad Company has petitioned the St. Louis County Court to allow an amendment to its petition of April 9, which asked for a permit to lay tracks on the National Bridge Road. The amendment requests a private right of way.

KANSAS CITY, MO.—The Metropolitan Street Railway Company is rushing work on its Eighth Street viaduct, and expects to have it completed within six weeks. The total length of the viaduct is 650 ft., and is just wide enough for two tracks. Seven hundred thousand pounds of steel have been used in building it, and the largest of the big girders that have been used weighs 20,000 lbs. This great mass of steel and the concrete approaches made a solid and durable base. The foundation has been put down to bedrock—that of the west approach being 34 ft. below the street grade. In order to meet the demands of property owners that the structure should be sightly and impervious, the whole track space will be covered with steel plates over girders on which ties are laid imbedded in bituminous concrete. On top of the ties ducts will be laid, carrying feeder cables, the ducts being imbedded in and surfaced over with sheet asphalt, giving the viaduct from overhead the appearance of an ordinary double-tracked street railway on a paved street. Eighty-pound rails will be used on the viaduct, and a safety appliance will be provided by an inner and outer guard-rail and guard-rails at the approaches. Except at the Main Street station, the viaduct has an incline of 6 ft. to over 100 ft.

GREENSBORO, N. H.—The City Council has passed an ordinance granting the Guilford Power Company a franchise to construct a street railway in Greensboro. The franchise is for thirty years, and provides for a single-track system, with one exception. The price of transportation is to be 5 cents within the city limits and six tickets are to be sold for 25 cents.

MIDDLESEX, N. J.—The South Amboy Borough Council has passed an ordinance granting the Middlesex & Somerset Traction Company a franchise for the construction of an electric railway through the borough.

NEWARK, N. J.—The North Jersey Street Railway Company formally opened its new line on Jackson Avenue, Greenville, June 28.

NEWARK, N. J.—The North Jersey Street Railway Company has commenced the operation of cast-welding its track joints. The Falk system is being used, and a 1-ton cupola has been purchased, together with the right to use it without paying royalties. From ten to eighteen joints are cast per ton of iron, according to the size of rail, and both new and old rails are being welded. Work is being carried on every pleasant night, but it will be some time before the entire undertaking is finished.

ALBANY, N. Y.—The United Traction Company has awarded J. M. Jones' Sons' Company a contract for twenty-five cars.

CATSKILL, N. Y.—The Catskill Electric Railway Company has purchased the necessary poles, ties and rails for the construction of 2½ miles of its proposed road, and is in the market for other supplies. The work of construction, placing of orders for equipment, etc., is in charge of Fowler & Robert, the well-known supply firm, of 149 Broadway, New York. Mr. Robert states that all orders will be placed immediately, and the road will be finished as soon as possible.

NEW YORK, N. Y.—On June 21 the Rapid Transit Commissioners voted to change the route of the subway at the northern end of the West Side line, so that it will go north in almost a straight line over a viaduct from the portal of the tunnel at Hillside Avenue to the terminus at 218th Street via Nagle, Eleventh and Tenth Avenues, instead of making a detour to the west through Ellwood Street to Inwood. The change will save 1000 ft of viaduct and $100,000 in the cost of building. Contractor John B. McDonald approves the change because the new route will be through a more thickly settled section and will pay better when the road is in operation.

Canadian Capital in the West Indies

Sir William Van Horn and James Hutchinson, of Montreal, and B. F. Pearson, of Halifax, are the principal members of a syndicate which is actively building and operating electric railways and lighting plants in the West Indies, among the latest ventures being a 10-mile railway at Demerara, and a 12-mile railway in Trinidad. The former will use Westinghouse 12A motors, single motor equipment, and in the power house will be Robb engines and one direct-connected 200-kw and one belted 100-kw Westinghouse generators.

Chicago Consolidated Traction Suit

Application has been made to the Circuit Court at Chicago by Sutro Brothers & Company, of New York, for an injunction to prevent the Chicago Union Traction Company from controlling the company. Sutro Brothers hold 700 shares of the stock of the Chicago Consolidated Traction. The claim made by Sutro Brothers & Company is that the mortgage for $6,750,000 was made by the Chicago Consolidated Traction Company with its own stock as collateral, as part of a plan to evade the law forbidding the purchase by one corporation of another corporation.

Street Car Riding as a Cure for Insomnia

After careful investigation a prominent Louisville physician announces that the most expeditious cure for insomnia is trolley car riding. He advocates a ride of about two hours before bed time, and says that a sound night's sleep will be enjoyed if his instructions are followed. "Two hours before bedtime," says he, "put on your most comfortable clothes, your easiest shoes and your least choky collar. Then walk to the nearest car line, take a front seat in the first open car that comes along, and sit there till time to go to bed, riding from one end of the line to the other, with the cool night wind blowing in your face. An hour's street car riding scarcely ever fails to bring on a feeling of drowsiness, and it has actually been able to bring sleep to the most nerve-wrecked of insomniacs by this simple device."

State Tax Board Must Review Assessments on Metropolitan Street Railway System

On July 6 Justice Herrick granted writs of certiorari directing the State Board of Tax Commissioners to review their assessments under the franchise tax law of sixteen railroad companies doing business in New York City. Following are the companies represented: Metropolitan Street Railway, Eighth Avenue, Sixth Avenue, Ninth Avenue, Second Avenue, Fulton Street Railroad, Twenty-Eighth & Twenty-Ninth Street Crosstown Railroad, Broadway & Seventh Avenue Railroad, Bleecker Street & Fulton Ferry Railroad, Thirty-Fourth Street Crosstown Railway, Central Crosstown Railroad, Christopher & Tenth Street Railroad, Twenty-Third Street Railroad, Central Park North & East Railroad, Forty-Second Street & Grand Street Ferry Railroad, and New York & Harlem Railroad Company, City Line.

Camden Company Rewards Faithful Employees

The employees of the Camden & Suburban Railway Company were given a surprise at the monthly "discussion night" of the Employees' Association in their rooms, July 9. After a discussion on "Car Brakes" a series of engrossed resolutions were presented to the directors. Later Superintendent Harrington, of the company, distributed envelopes to certain persons as their names were called. They found that those who had been in the employ for five years were given an order for a suit of uniform clothes and were entitled to wear one stripe on the arm. For service from ten to fifteen years, the order called for two suits of clothes and two stripes. For those more than fifteen years, orders for a summer and winter uniform and an overcoat were given. Simeon Matlack, the oldest employee, will be entitled to wear five stripes. He has been connected with the company for more than twenty-seven years.

Liability of Elevated Roads for Damages to Abutting Property

The finding of the lower court at Chicago in favor of a West Lake Street property holder in a suit brought against the Lake Street Elevated Railroad in which he alleged damages on three grounds, namely, interference with light and air, and noise, and with ingress to and egress from the property, has been overruled by the Appellate Court, and judgment entered for the defendant. The

higher court holds that the structure does not interfere with ingress and egress by the streets, and says that specific proof must be shown as to the damage resulting from interference with light and air and from noise. In reference to smoke and noise the court quotes from a decision in another State as follows: "These in the form in which they appeared to exist from the proofs were incidents of city life and not substantial injuries." From another decision the court quotes: "The owner of land abutting on a street holds title subject to the inconveniences and injurious consequences, including those occasioned by noise and vibrations resulting from a user which is consistent with the legitimate and proper use to which a public thoroughfare was dedicated."

Court Upholds Assessors' Street Railway Valuations at Detroit

The Wayne Circuit Court has decided that franchises are assessable, and that the street railway companies must pay taxes on the increased assessment made by the board of assessors. The court holds: That all franchises are taxable as personal property; that the city has no authority to bargain in taxation, but must assess the property of all corporations alike; that if any property is to be exempted from taxation, all must be; that no property must be required to bear more than its just share of the burden of taxation.

The assessment made this year by the board of assessors is as follows:

Detroit Citizens' Railway Company	$5,521,100
Ft. Wayne & Belle Isle	1,051,200
Detroit Electric Railway Company	1,569,800
Grand River Avenue Line	2,104,900
Total	$10,247,000

The assessment last year was:

Detroit Citizens' Railway Company, including the Grand River Line	$1,500,000
Ft. Wayne & Belle Isle	300,000
Detroit Electric Railway Company	800,000
Total	$2,600,000

The street railway companies stated that they will carry the case to the higher courts. If the decision is sustained the companies will have to pay the city taxes as follows:

Detroit Electric Railway	$23,832
Grand River Line	31,956
Detroit Citizens' Company, on suburban line out Jefferson Avenue	759
On North Woodward Avenue	2,277
On Mack Avenue	227
On Gratoit Avenue	91
Rapid Railway	3,340
Detroit, Ypsilanti & Ann Arbor	5,389
Detroit & Northwestern Railway	309
Total	$68,180

Big Deal in Philadelphia

A special dispatch from Philadelphia announces that the Investment Company of Philadelphia has secured control of the Railways Company General. As a part of the arrangement, the company receives about $300,000 new cash capital, $200,000 of which will be applied to liquidate the entire floating debt, and $100,000 to retire underlying bonds. It is announced that there will be no additional issue of stock or bonds. The authorized stock of the company is now $10,000,000, of which $1,500,000 is outstanding. L. N. Downs has resigned as president of the Railways Company General, and is succeeded by Evans R. Dick, president of the Investment Company. John B. McAffee will remain as vice-president and general manager of the company. The new directors of the company are: Evans R. Dick, J. Ogden Hoffman, R. H. Rushton, representing the Investment Company, and J. Cooke, of C. D. Barney & Co. J. W. Supplee, late president of the Corn Exchange Bank, had accepted a position as director, but his sudden death leaves the place vacant. The retiring directors are: Edwin S. Cramp, Dr. W. H. Chestnut, Major L. N. Downs, Richard Ellis and Edwin F. Glenn. The old members who remain in the board are: George S. Graham, W. W. Gibbs, S. B. Vrooman and Robert J. McKinstry.

The Railways Company General was incorporated in August, 1899, under New Jersey laws. It owns and controls the following properties: Montoursville Passenger Railway; Milton, Lewisburg & Watsontown Electric Railway; Philadelphia & Bristol Passenger Railway; Michigan Traction Company; Elmira & Seneca Lake Railway Company; Newtown Electric Street Railway and American Engineering Company.

San Francisco Transfer Ordinance Held Valid by the Supreme Court

The Supreme Court of California has rendered a decision declaring the San Francisco transfer ordinance valid. The ordinance is designed to correct and prevent abuses of the transfer system by requiring a street car passenger to use his transfer within the time limit, and prohibiting him selling or giving it away. This verdict is a decided victory for the companies, and will put a stop to fraudulent practices of ticket sharps, etc.

The ordinance was attacked on the ground that it violated the guaranty of personal liberty contained in the constitutions of United States and the State of California; that it was an unconstitutional interference with a right of private property; that it was arbitrary, oppressive, and unreasonable; and that it was an illegal attempt to enforce the obligations or assumed obligations of private civil contracts by penal legislation.

After a review of these contentions the court held that the ordinance was valid. In regard to the argument that the ordinance was an attempt by penal legislation to enforce a private civil contract, or, in other words, that it was an attempt to compel the passenger who has received his transfer to use it within the limits of his contract, and not to violate that contract by giving it to a person who might make improper use of it, the court said: "Could it be perceived that this was the only purpose, or even the main purpose, of the ordinance in question, we should be inclined to hold that the objection was fatal, but we cannot perceive that its main object or design was to accomplish this result. Rather, we think it clear that its primary object is to protect and advance the convenience and welfare of the traveling public; for if, to the legislative mind, an abuse of the transfer system has grown up, the inevitable result of such unrestricted abuse must be one of two things—either that transfers would be discontinued entirely, to the material injury of the community, or the transfer system would be hedged and safeguarded by onerous conditions and requirements for the protection of the company, which would work great inconvenience to the passengers. It was certainly right for the supervisors, if they saw or anticipated the existence of such an evil, to destroy or avert it by proper legislation tending to correct the abuse, and it is no objection to the validity of an ordinance designed for this purpose that it may incidentally tend to prevent frauds and compel men honestly to abide by their contracts."

The St. Louis Strike on Again

The great street car strike at St. Louis was declared off on July 2, and was declared on again July 10, the executive committee of the local union declaring that the St. Louis Transit Company had violated the contract which was signed by both parties on July 2. This agreement follows:

1. The provisions of the agreement of March 10, 1900, as to rates of pay and hours of service will be continued in force by the company.
2. Every employee of the company to be free to join or not to join any organization, and no discrimination to be made for or against him because of the manner in which he exercises his freedom.
3. Any attempt on the part of any employee to induce another employee by intimidation or threats to join or not to join any union shall be cause for immediate discharge of the person guilty of such attempt.
4. Any attempt to influence any employees by an official of the company to join or not to join any union shall be cause for discharge of such official.
5. The company will meet any employee or committee of employees, whether representing themselves, other employees, or an association of employees, regarding any matter of mutual interest.
6. For the purpose of filling vacancies which may now exist or hereafter arise, the committee of former employees, of which T. B. Edwards is chairman, shall prepare a list of the men who were in the company's service on May 7 last, and as the company now or hereafter needs additional men it will select them exclusively from this list until it is exhausted, not interfering, however, with men now in the service. No person shall be eligible to this list who has been guilty of any acts of lawlessness or violence.

St. Louis Transit Company,
by Edward S. Whittaker, President.

T. B. Edwards, Chairman of Committee.

The strike is hereby declared off.

T. B. Edwards, Chairman of Committee.

July 2, 1900.

Certain members of the union claim that the company broke clause 6 of the agreement by hiring non-union men since the strike was declared off, July 2. The company enters a general denial of the charges, and says that help contracted for from outside sources before July 2 and who did not arrive till a later date were appointed, but other than this no help has been engaged. The company is in duty bound, the management explains, to give these men positions. It is earnestly hoped that the citizens of St. Louis will not have to tolerate a similar condition of affairs to that which existed during the last strike, and that the present difference be settled speedily. The city authorities should take hold of the situation at once, and prevent a repetition of the acts of the last strike.

The recent struggle between the St. Louis Transit Company and its employees has been worse than famine and pestilence to St. Louis, and it will take many days for the city to blot out the disgrace to its name. The monetary loss to the city is inestimable.

Sixteen lives were lost in the last strike, over one hundred persons wounded by bullets and thrice that number injured by missiles or explosions. In addition to the fatalities and casualties reported, the north and south ends of the city developed a species of brutality never before witnessed in a civilized community, women being stripped of their clothing in the public streets and then beaten for having ridden on Transit cars. As a result of the boycott declared by the strikers, several of the small merchants have been forced into bankruptcy, and nearly every line of business more or less seriously affected.

Japanese Railroad Officials and the Brooklyn Rapid Transit System

In the STREET RAILWAY JOURNAL for June 16 an account was given of a trip over the lines of the Brooklyn Rapid Transit Company, made by Y. Sasaki, general manager of the Nankai Railway,

VIEW OF SPECIAL CAR CARRYING JAPANESE RAILROAD OFFICIALS

and K. Nishino, traffic manager of the Sanyo Railway, of Japan. The engraving above shows the end of the parlor car Columbia, made from a photograph taken in front of the entrance to the Kent Avenue power station of the road. Looking at the picture, Mr. Sasaki will be seen on the extreme right, while Mr. Nishino stands immediately behind. The two other Japanese are New York friends of Messrs. Sasaki and Nishino. The person on the extreme left is John M. High, general sales agent of the Pantasote Company.

The parlor car, with the persons named, and other invited guests, left from the Manhattan end of the bridge at 2 o'clock, and went immediately to the Kent Avenue power station, via the Brooklyn Borough Hall and Myrtle and Washington Avenues, passing the Navy Yard. After a thorough inspection of that plant, the car returned to the Borough Hall, and was met by J. C. Breckenridge, general manager of the B. R. T., who escorted the party through to Fifty-Second Street power house and shops, where everything was fully explained by Eugene Chamberlain, superintendent of equipment. From there the entire party, including also Superintendent Robbins, went to Brighton Beach, where supper was served at the Brighton Beach Hotel.

Messrs. Sasaki and Nishino left Japan November last, and after visiting all the important cities in Europe, came here to study our methods of transportation. Mr. Sasaki left for home the end of June, and Mr. Nishino is now in the West on his way to San Francisco, from which place he will sail week after next. Both gentlemen expressed themselves as much pleased with our decidedly advanced methods of conducting traffic, and spoke also of the great amount of American machinery they had seen in all the countries they visited.

Opening of the Central London Underground Railway

[*From Our Regular Correspondent.*]

A most important event took place June 27, when His Royal Highness the Prince of Wales made a formal inspection of the Central London Railway, which, as readers of the STREET RAILWAY JOURNAL are doubtless aware, is a new underground railway in London, and declared the railway open. The occasion was naturally one of great importance, not only to street railway or tramway men, but also to the railway world in general, and some 500 representative men from all over Great Britain assembled to witness the interesting ceremony. The Prince of Wales arrived at the Bank station of the railway about 3:30 in the afternoon, and was received by Sir Henry Oakley, the chairman of the Central London Railway Company and his co-directors. The station at the Bank is all but completed, and in passing through the station it was noticed that the American system for the collection of fares, as adopted on the elevated railways in New York, was to be utilized in this new London railway, and familiar looking boxes, with the chopping machine handle, were in strong evidence, to which all New Yorkers are well accustomed. Previous to the arrival of the Prince a large number of the guests had preceded him on two other special trains, which made quick journeys from the Bank to Shepherd's Bush, a distance of about 6½ miles, where the central station is situated.

The royal train accomplished the journey in about eighteen minutes, and it is safe to say that even His Royal Highness never traveled in greater comfort than on this occasion. The roadbed and rolling stock of this new enterprise are beyond reproach, and the cars travel as smoothly as it is possible to imagine. At the power house a special platform had been erected, and after the Prince alighted no time was lost in walking into the power house for a short and informal inspection, which the Prince seemed to manifestly enjoy, and to be intensely interested in. Shortly afterward refreshments were served under the direction of the manager of the Carlton Hotel in a large marquee, which had been admirably and most tastefully decorated for the occasion. A large, round table was provided for the Prince of Wales, at which were also seated Sir Henry Oakley, the Duke of Fife, Sir Michael Hicks-Beach, Lord Rothschild, the Marquis of Londonderry, Lord Claud Hamilton, Mr. Henry Chaplin and Lord Stalbridge. The rest of the space was occupied by a number of small tables beautifully decorated with flowers, at which a most recherche luncheon was served, and at some of these tables might be noticed the following gentlemen: Lord Colville, of Culross; the Lord Mayor, Sir Courtenay Boyle, Sir Benjamin Baker, W. L. Jackson, M. P.; Lord Farquhar, Captain Holford (in attendance on the Prince of Wales), Sir Richard Farrant, the Hon. Algernon Mills, the Earl of Cork, Lord Rathmore, Sir Ernest Paget, Sir W. H. Preece, Mr. Perks, M. P.; Sir J. W. Maclure, M. P.; C. F. Gooday, H. C. Stephens, M. P.; Henry Tennant, Francis Hopwood, the Hon. Charles Rothschild, Sir Ernest Cassel, Sir George Lewis, Sir Francis Knowles, Sir John Monckton, Sir Arthur Arnold, John Aird, M. P.; W. Forbes, Lieutenant Co. Yorke, W. H. Turner, Alfred Powell and Sir F. Dixon Hartland, M. P.

There was no formal speechmaking, but the Prince of Wales in a few graceful words, proposed the toast of the Central London Railway, as follows: "I have much pleasure in declaring the Central London Railway open to-day (cheers), and am glad that I

have been asked to take part in the ceremony. I wish to drink success to the undertaking, and to congratulate Sir Benjamin Baker, the eminent engineer, who has constructed this railway. I have little doubt but that it will be a great boon to this city. I am sure you will all join with me in drinking success to the company. (Cheers)." After enjoying the hospitality of the Central London Railway, and evidently greatly enjoying his surroundings, His Royal Highness took train to Lancaster Gate station of the railway, and shortly afterward the company dispersed.

The whole affair in every sense of the word was most successful, and too much praise cannot be given for the manner in which all the arrangements were carried out, and the extremely adequate provision made for the reception of the company's guests. As to the working of the system nothing could be left to be desired. The engines and generators worked with the precision of a well-established plant, and as has already been said, the cars traveled with all the smoothness that could be desired on the most perfect steam railroad in the world. The Central London Railway Company is certainly to be congratulated upon the completion of a most magnificent piece of mechanical and electrical engineering, and the British Thomson-Houston Company, contractors for the electrical work, and H. F. Parshall, the electrical engineer, are also to be congratulated upon the success attending their part of the work.

The ceremony was one of the most pleasant, most agreeable and most interesting which I have ever attended, and I think will be long remembered by those who had the good fortune to be present.

A. C. S.

Operating Work as a Feature of Electrical Laboratory Training *

BY WM. S. ALDRICH

In the representative institutions the engineering courses are now so organized that the junior student enters the engineering laboratory fresh from work in the physical laboratory. Advanced work along similar lines is carried on in many cases after the student has entered upon his professional studies. The earlier training is chiefly by way of illustration and demonstration, familiarizing the student with the phenomena, principles and laws of physics. The later training acquaints the student with some of the exact methods of modern experimental work. In consequence of such work, the engineering student should early assume toward all phenomena and problems in the realm of physics that attitude so characteristic of the scientific mind. Granting its thoroughness there is less necessity for attempting similar training in the engineering laboratory. More time is, therefore, available for developing the latter along engineering lines.

The work of physical and of engineering laboratories naturally overlap each other. No hard and fast line can be drawn between them. It becomes daily more impossible to define clearly their respective limits with each advance in physical science and growing industrial applications of the same. In the engineering laboratory are investigated the properties of water, steam, gas and electricity with special reference to their industrial applications; the chemical, physical, mechanical, electrical and magnetic properties of materials, as the case may require; the functional relations of mechanisms, machinery and prime movers, and their performance in detail or in the aggregate.

The bearing of these considerations upon electrical laboratory training is obvious. Preceding experimental work with new electrical appliances or processes there should be carefully arranged work along the following lines: study, inspection, illustration and demonstration, operation. By thorough study of actual and typical appliances the necessary preliminary electrical and mechanical data are secured. By inspection the student is assured of the electrical, magnetic and mechanical condition of the apparatus essential for successful operation of the same. By way of illustration and demonstration he is familiarized with the phenomena and principles underlying the functional working of apparatus and the handling of instruments and circuits. By operation the student acquires that familiarity, facility, confidence and resourcefulness so essential for the satisfactory handling of electrical circuits and appliances.

Training in handling electrical machinery is quite as essential as training in electrical measurements. The one should be done and the other not left undone. If with all of his familiarity with galvanometer work the young electrical engineer is left to the mercy of the wireman or the operating engineer, his laboratory training has been incomplete. A knowledge of the behaviors of electrical machinery and confidence in handling electrical circuits is becoming more necessary with each widening use of electricity. The utilization of alternating currents and the operation of alternating current machinery constitute to-day a most interesting and important field, one with which the electrical student cannot become too familiar. It is the result of experience that students who have been given a course of electrical laboratory training involving study, inspection, illustration and operation have a better understanding of testing work than if they had been put at once into the latter without attention to the former.

* Abstract of a paper read before the Society for the Promotion of Engineering Education, New York meeting, July 2-4, 1900.

Calculation of Distributing Systems of Electric Traction Under British Condtions IV.

BY H. M. SAYERS

(Continued from page 602.)

APPENDIX No. IV.

CALCULATION FOR TRACK FEEDER, EAST OF T

Rail resistance, .0289 *w* per mile.
Drop allowed, 5 volts.
Amperes × miles constant for 5 volts = 173.
Current per car, 15 amps. Cars passing in pairs.
From T Eastward.

Cars		Amp. miles	Product	Sum
T to F, 5 cars, .9 miles.	First pair	30 ×	.3 = 9	
	Second pair	30 ×	.6 = 18	
	One at F	15 ×	.9 = 13.5	
	Two on line D F	30 ×	.9 = 27	67.5
F to G, 4 cars, 1.25 miles.	First pair	30 ×	1.21 = 36.3	103.8
	Second pair	30 ×	1.83 = 54.9	158.7
	Two on line N G	30 ×	2.15 = 64.5	223.2

As the sum is brought over the constant by the current flowing in at G from branch N G, G should be a point of change of direction. The product of amperes × miles on branch N G is 15 × 1.1 = 16.5. This added to the 158.7 at G = 175.2, a little over the limit. Hence the whole of the 30 amps. from branch N G should flow east, and the integral of ampere miles from G to feeding point should be 173 — 16.5 = 156.5, to keep N at 5 volts.

Then from G Eastward. Section G O, four cars.

1.5 miles long. Currrent flowing east 30 amps. from branch N G.

Cars	Amp. miles	Product	Sum
At G	..	16.5	..
G to first pair	30 × .375 =	11.25	27.75
First pair to second pair	60 × .75 =	45.00	72.75
Second pair to O	90 × .375 =	33.75	106.50

H being terminus, and only two cars between H and O, it is obvious that feeding point should be west of O, so sum westwards from H. H to O 1 7 m.

Cars	Amp miles	Product	Sum
First pair to O	30 × .85 =	25.5	
O to second pair G O	30 × .375 =	11.25	36.75
Second to first pair G O	60 × .75 =	45.00	81.00

Feeding point will thus be between the first and second pair of cars east of G. It should be exactly .825 miles east of G. The product from this point will be 54.75 to the terminus H and to N, corresponding to 1.58 volts drop. Hence the feeding point may be 3.42 volts above earth.

The track feeder will have to carry back 120 amps., and be 2975 miles long. Section should be .39 sq. in., and the drop in it will be 15.06 × 2.975 = 45 volts. But as its end may be 3.42 volts above earth, the booster will have to give only 41.58 volts, and have an output of 41.58 × 120 = say, 5000 watts.

TRACK FEEDER NO. 2

From T Westward

It is obvious to inspection that some current should return *via* D and some *via* J. The dividing points should be those at equal distances from T by each route.

On the branch D J this point is practically at the center of its length, hence half the total current is taken as flowing each way.

On the circuit T D C I J T, it is very close to the junction, I. Hence the current returning by J will be half that on the branch D J, and the whole of that on branches from J to I, K and L respectively, making altogether 8.5 × 15 = 127.5 amps., which gives at once the section of the track feeder from T to J. It also follows that the potentials of points D and J should be kept equal. Find feeding points, etc., as before.

T to D, seven cars, 2.35 miles. Branch C M, four cars = 60 amps. at .35 miles from T.

Assume one car at D, the other six in pairs at .59, 1.18 and 1.77 miles respectively from T.

* Paper read before London Institution of Electrical Engineers, May 3, 1900.

CURRENT EASTWARD TOWARD T

Cars	Amp. miles	Product	Sum
T to C	60 × .35 =	21.00	
T to first pair	30 × .59 =	17.70	38.7
T to second pair	30 × 1.18 =	35.40	74.1
T to third pair	30 × 1.77 =	53.10	127.2
T to D	15 × 2.35 =	35.25	162.45 = 4.7 V
T to O, part current from branch D J	44 × 2.35 =	10.5	173

giving 5 volts at D.

CURRENT WESTWARD FROM D

D to C, 1.65 miles, six cars, passing at .41, .82, 1.23 miles from D, 33 amps. from branch D J also :

Cars	Amp. miles	Product	Sum
D to first pair	33 × .41 =	13.53	
First to second pair	63 × .41 =	25.83	
Second to third pair	93 × .41 =	38.13	
Third to C	123 × .41 =	50.43	127.92 at C

Count back from A to find equal point.

A to B, 2 miles, three cars, assume one at A, two in middle.

CURRENT EASTWARD FROM A

Cars	Amp. miles	Product	Sum
A to first pair	15 × 1 =	15	
First pair to B	45 × 1 =	45	60

B to C, 1.1 miles, two cars, assume in middle, current of one car from branch B J. Continue summing from A.

Cars	Amp. miles	Product	Sum
B to middle	60 × .55 =	33	
Middle to C	90 × .55 =	49.5	142.5 at C

This indicates feeding point a little west of C, but as 60 amps. more enter from branches north and south of C, and C is the meeting place of four tracks, it is clearly the proper place for the feeder to tap the rails. If this point be kept at earth potential, A, the point furthest from T will be at 4.1 volts above earth.

The feeder will be 4 miles long, have to carry 273 amps. back, have a section of .89 sq. in., will drop 4 × 15.06 = 60.24 volts, and booster must give 273 × 60.24 = 16,445, say 17,000 watts.

TRACK FEEDER NO. 3

Inspection of the diagram suffices to show that J must be the feeding point for this. The greatest drop thence will be on branch J K, 2.2 miles long with two cars. Assume one at K and one half way, then ampere miles K J will be 41.25 or 1.2 volts. J must then not be more than 3.8 volts above earth. This is lower than D, so that more than the half current on line J D will return by the feeder *via* J. *Per contra* part of the current from branch I J will go *via* I C. The assumed distribution could be obtained by splitting the feeder at J, and connecting the branches at proper points on the three lines J L, J K, J I.

No practical advantage would result, as in working the load on each feeder is regulated to keep the pilot wire indications within proper limits, by control of the booster e. m. f., and it is quite certain that the actual load and its distribution will vary widely and rapidly in any given case from any assumed distribution, consequently in a network requiring a number of track feeders it is sufficient to ensure that they shall be provided of needful section and number to enable the P. D. on the rails to be kept within limit, and refined investigation of the current distribution is likely to be labor lost.

Hence No. 3 feeder may be safely taken as tapping rails at J. It will be 2.15 miles long, carry 127.5 amps., have a section of .415 sq. in., drop 32.4 volts, and require a booster to give 32.4 × 127.5 = 4130, say 4200 watts.

DISCUSSION

The following digest of the discussion on Mr. Sayers' paper is taken from the London *Electrical Review*:

The discussion was opened by Prof. Andrew Jamieson, who regarded the paper as one which contained a great deal of sound matter requiring special study. He referred to his visit to Cape Town in connection with the tramways there, and stated he found no less than thirty volts between the end of the lines and the power house. The result was electrolytic troubles and disturbance on the submarine cables. He advocated the use of boosters. Owing to the extraordinary character of the slate formation, forming a basin in which Cape Town lay, the rails returned only about 70 per cent of the current, and 30 per cent went out to sea.

Mr. Taylor spoke of the paper as being a thoroughly practical one, discussing in detail the advantages from a distributing standpoint of the single and double station and the polyphase system. He had applied some of the calculations to light railways. Advocates of high-tension transmission might try to reduce the costs of that method, but even supposing that those items most readily dealt with were halved, it would reduce .352d. to .292d. only. Mr. Sayers had taken a case rather in favor of the polyphase transmission, as he assumed 28½ miles of track, fifty-seven cars, and a heavy car mileage per annum. Attendance at the sub-stations reckoned at 3s. per week each seemed distinctly low and rather in favor of polyphase. The high losses were due to transformers. Mr. Taylor then showed how the cost was effected by frequency of service, and discussed whether the question of distance of transmission did or did not depend upon the distribution of traffic. He dealt with the arrangement of boosting described in the paper, which only appeared to allow for boosting on the portion of the length of trolley line supplied, and not also on the feeder line to the section fed by it.

Eustace Thomas took up the question of most economical distribution, and gave, as his opinion, that generally the systems put down had regard to first cost rather than economy. It perhaps seemed absurd to talk of another way of putting Kelvin's law, but it was apparently more accurate than the ordinary mode of expression. Take out the cost of 1 mile of cable; if any given size be taken, it is a question whether it would not be better to have a larger size. Let the resistances of the cables be R_1 and R_2, then the power wasted in each would be $R_1 K_1$ and $R_2 K_1$, while the interest, etc., charges would be $P_1 K_2$ and $P_2 K_2$, and to get the best result,

$$(R_1 - R_2) K_1 = (P_2 - P_1) K_2$$

or

$$\frac{R_1 - R_2}{P_2 - P_1} = \frac{K_2}{K_1}$$

where $\frac{K_2}{K_1}$ depends only on the system adopted, and not on the size of the cables. For a given case he had worked out, the figures were:

$\frac{19}{16}$ > 406

$\frac{19}{15}$ > 624

$\frac{19}{14}$ > 1,130

$\frac{19}{13}$

$$\frac{K_2}{K_1} = \frac{C^2 \times \text{hours per day and cost of extra unit from station.}}{\text{Percentage rate of interest, maintenance and depreciation.}}$$

and the result gave 616, showing that about $\frac{19}{15}$ was the most economical size.

Mr. Jenkin pointed out that the paper did not compare the one and two station, and the polyphase systems of supplying tramways; interesting as it was, the matter could not be generalized. He thought feeders should be run to separate sections of line, and two cars might connect the feeders at different parts of the line.

E. K. Scott thought the polyphase system would have shown better if taken at 5000 volts instead of 2500 volts. No attention at the sub-station would be required if the polyphase system were assumed to be used directly on the cars.

Mr. Swinburne had always some fear in discussing such a paper, but he regarded the risk of a departure from accuracy to get simplicity as very real. Under actual circumstances, insulation comes in; this does not vary as the cost of copper, and Kelvin's law in its simple form does not apply. Another element was the eating of pipes that were "not ours," the private individual could not do so, but he supposed tramways could eat pipes as much as they liked provided they followed the Board of Trade regulations. Seriously, the corrosion of pipes, he was afraid, would be most serious. He thought the three-wire system had not been sufficiently considered, but the present Board of Trade rules will not fit three-wire systems. He supposed the reason why this method had been overlooked was that some American had said they did not do such things in America. He wished to state that the booster system is perfectly applicable to the three-wire system, and the bigger the system is the easier it would be to manage. Finally, the way out of the difficulty would be to put a booster on pipes.

E. T. Carter asked if the three-wire system was not in use on the City & South London Railway, and Mr. McMahon said it was, and the balancing was effected by battery and sub-station balancers.

R. C. Quin differed from Mr. Sayers as to a drawing-in system for cables. He had used both, and concluded that if you draw in you will have to draw out, whereas if laid solid, or buried, not only is cheapness gained, but no necessity will arise for removal. He, as a municipal and tramway engineer, preferred granite setts between tramlines, because the traffic was always heaviest on the crown of the road, and the granite setts tended to keep down the excessive wear. He regarded reliability as worth something more than a few pounds, and with all transformer systems there was something to break down.

Major-General Webber compared tramway and telegraph pole fixing and cable systems, and severely criticised the way in which trolley poles were erected in many cases, a neglect of the stresses and strains being shown. He advised tramway engineers to study the question of strains on poles, and learn what they could from the experience of telegraph engineers.

Mr. Sayers, in reply, felt happy that there had not been much contradiction or destructive criticism. He admitted his estimate

of attendance on sub-stations (3s. weekly) was low. The greatest density of traffic affected the size of feeders, and not the distance of distribution. He considered the method he gave for calculation more general than that of Eustace Thomas, as one got the general expression for the most economical density. He did not profess to compare systems. Each section of trolley wire would, of course, be fed at many points. He thought E. K. Scott quite right as to use of motors on cars, and that Mr. Swinburne's remarks were worthy of attention; the difficulty was to find anyone who would put down money to equip such a system. The trouble lay in shorts and turn-outs. It would require a paper to reply to Mr. Quin, but the life of a cast iron pipe was forty years, and he did think that that provision is worth greater attention.

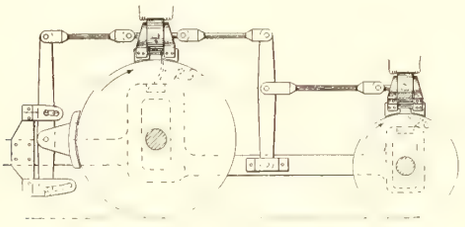
Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED JUNE 26, 1900

652,248. Fish-Plate; W. H. Connell, Wilmington, Del. App. filed March 18, 1898. The plate is provided with three inwardly turned flanges, one of which presses against the under side of the tread, another against the top of the base flange, and the third extends under the base flange.

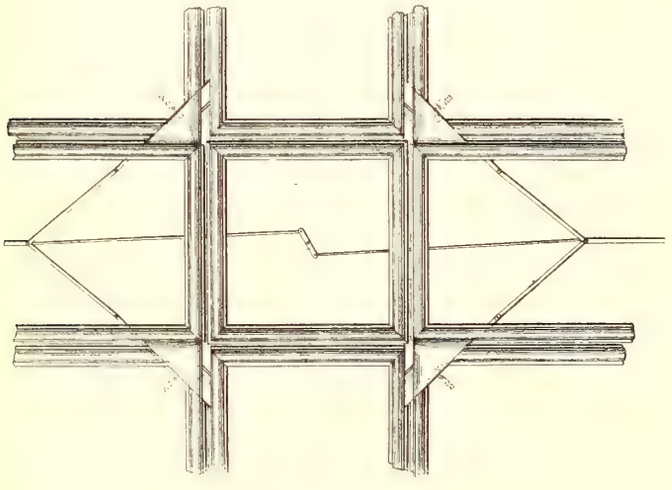
652,265. Railway Tie; R. E. Heller, Abingdon, Ill. App. filed Nov. 28, 1899. The tie is constructed with springs and elastic walls so as to yield under the weight of the train, and make the riding smoother.



PATENT NO 652,266

652,266. Electromagnetic Brake; E. M. Herr, Pittsburgh, Pa. App. filed Nov. 18, 1899. A magnetically applied brake shoe and a mechanically applied shoe are so connected together that when the former is operated, it will also cause the movement of the latter against the wheel.

652,282. Rail-Joint; J. O. Mayhall, Roxie, Miss. App. filed Oct. 21, 1899. The fish-plate interlocks with the rail end in such a way as to prevent longitudinal separation of the rail.



PATENT NO. 653,006

652,415. Repairing Railroad Ties; C. F. Young, Grand Rapids, Mich. App. filed April 4, 1900. A mortise or dado is cut in the tie immediately beneath the rail to receive a removable wooden seat for the rail.

652,487. Rail Joint; J. N. Powers, Shreveport, La. App. filed Feb. 21, 1900. A metal plate extends under the rails and across the joint, and the fish-plates which embrace the rail are bolted to this plate.

652,620. Vestibuled Car; W. M. King, Sr., and H. Jones, Alexandria, Va. App. filed March 28, 1900. The side door of the vestibule is so connected with that portion of the floor above the steps that the latter will be opened and closed when the door is opened and closed.

652,627. Car Seat; W. M. Norcross, Philadelphia, Pa. App. filed April 13, 1900. This invention, which consists of the details of construction relates to that class of seats in which the back section can be swung from side to side, and in which the seat section is tilted or inclined by the act of shifting the back section.

652,613. Overlapping Railway Rail-Joint; F. B. Hart, Manchester, Eng. App. filed April 16, 1900. In rail-joints of the overlapped character the rail ends have bent overlapping webs, provided with extensions beyond the bends, which lie parallel to the ordinary webs of the rail, and are provided with a sufficient number of suitably formed bolt holes for the secure attachment of the rails to one another.

UNTED STATES PATENTS ISSUED JULY 3, 1900

652,767. Tramrailway Track for Public Highways; T. H. Gibbon, Philadelphia, Pa. App. filed Oct. 14, 1899. The tread of the rail is made broad to furnish a track for various kinds of vehicles, including wagons, automobiles and bicycles. The invention relates particularly to the manner of securing the broad tread to the web of the rail.

652,863. Wheel Guard; R. F. Pruesser, Washington, D. C. App. filed Dec. 6. 1899. This is a fender and wheel guard combined, since it is adapted to be thrown down against the roadbed by the motorman to take up an obstruction.

653,006. Railway Crossing; J. S. Jenckes, Jr., Terre Haute, Ind. App. filed April 20, 1900. Blocks are arranged at the crossings of the rails to slide in such a way as to make either of the crossing rails continuous, at will.

653,056. Car-Brake Device; J. S. Baker, Beverley, Mass. App. filed Nov. 7, 1898. This brake is operated by a hand wheel set on a horizontal axis; a clutch is arranged between the wheel and staff, which automatically releases and locks the staff to receive and hold any pressure upon the brake rigging.

653,108. Railway Switch Setting Mechanism; G. W. Mockabee, Washington, D. C. App. filed April 20, 1900. Details.

653,154. Car Fender; J. Sullivan, Boston, Mass. App. filed March 29, 1900. A car buffer and fender; a bar arranged longitudinally under the front end of the car body, and held by a spring, so that its forward end is in contact with the buffer, said bar having a projection on its upper side and a disc on the upright rod, said disc having a tooth or projection in contact with the former projection for operating the fender.

PERSONAL MENTION

MR. EDWIN REED, civil engineer of the Scranton Traction Company, of Scranton, Pa., was married to Miss Esther Smith June 27.

MR. F. L. BEARDSLEY has been appointed superintendent of the Derby Street Railway Company, of Derby, Conn. Mr. Beardsley was formerly assistant treasurer of the company.

MR. W. N. VOORHES has resigned as superintendent of the Smith Street car shops of the Coney Island & Brooklyn Railroad, of Brooklyn. Mr. Voorhes has been in charge of the shops for the past ten years.

MR. FRANK A. DRAPER has recently been appointed superintendent of the Detroit & Northwestern Railway, of Detroit, Mich. Mr. Draper was formerly connected with the Detroit, Rochester, Romeo & Lake Orion Railway, and with the Shore Line.

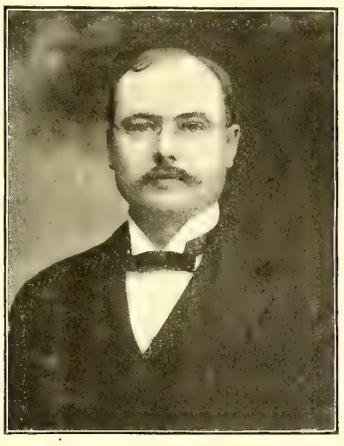
MR. GEORGE F. GREENWOOD, formerly general manager of the Pittsburgh Consolidated Traction Company, and now general manager of the Havana Tramway system, is about to abandon bachelorhood, his engagement to a daughter of Mr. W. M. Doull, treasurer of the Cuban Electric Company, being announced. The date of the marriage is set for July 12, and will occur in England.

MR. CHARLES F. LUTHER, who severed his connections as superintendent of the Pawtucket Street Railway Company, of Providence, R. I., July 1, was presented with a handsome clock by the employees of the company as a token of the esteem in which he was held by them. Mr. Luther has been connected with the street car service of Providence since 1886. He was in turn cashier and secretary and general manager of the company. In 1894 he was appointed superintendent of the company. Mr. Luther is succeeded by George R. Cook.

MR. JULIUS F. PRATT, of Indianapolis, vice-president and treasurer of the Atlas Engine Works, of Indianapolis, died at Glengariff, Ireland, July 7, where he had only recently arrived in

the course of a tour abroad for health and recreation. Mr. Pratt was widely known, and had many business connections. At the time of his death he was a director of the People's Gas Company, Parry Manufacturing Company, Merchants National Bank of Indianapolis, and proprietor of a wheel manufacturing company at Davenport, Ia., beside being connected with the Atlas Works Mr. Pratt was born in Worcester, Mass. Early in life he went West, and eventually settled in Indianapolis, entering the employ of the Woodburn-Savern Wheel Company, of which he later became one of the proprietors. On the absorption of that company by the American Wheel Company he was elected president of the new company, serving in that capacity until the dissolution of the company. He then became interested in the Atlas Engine Works. Mr. Pratt is survived by two daughters, both of whom were with him when he died.

MR. CHARLES O. KRUGER, who has recently been elected second vice-president and assistant general manager of the Union Traction Company, of Philadelphia, has served with the company as its secretary and treasurer since its organization in 1895. Mr. Kruger is also secretary and treasurer of the People's Traction Company, now a constitutent of the Union Traction Company, and has held this position since the organization of the People's Company in 1893. Mr. Kruger is a native of Philadelphia. He was born there on Dec. 14, 1864, and was educated in the public schools of the city, which he attended until January, 1882. On Feb. 21, 1882, he entered the employ of S. & W. Welsh, merchants and bankers, and remained in their employ until elected secretary and treasurer of the People's Traction Company in 1893. To Mr. Kruger has devolved a large part of the organization of system of the Union Traction Company, and the success achieved by that company has been in large part due to his efforts.



CHAS. O. KRUGER

NEWS NOTES

[News notes for this department are solicited.]

LITTLE ROCK, ARK.—The street railway franchise committee has decided to advertise for sale the franchise now being sought by the Little Rock Traction & Electric Company and Mrs. James R. Miller. There is every indication of a spirited fight for the franchise. Mrs. Miller has offered $101,000 for the franchise, and the Little Rock Traction & Electric Company $15,000 in cash for a thirty-year franchise, with 1½ per cent of the gross earnings for the first fifteen years and 2 per cent for the remaining fifteen. The company also agrees to carry the members of the police and fire departments free when uniformed. If they secure the franchise they propose to construct two additional lines, one west on Twenty-Second Street from Main to Ringo Street, and one south on College Street from Ninth Street to Oakland Cemetery.

NEW HAVEN, CONN.—The Winchester Avenue Railroad Company has just published a descriptive booklet of New Haven and West Haven, with illustrations showing views in both cities. The route of the Winchester Avenue Road is described from the Green to Woodmont, and all the points of interest along the road entertainingly treated.

ATLANTA, GA.—Judge J. H. Lumpkin, of the Superior Court, has decided that the Atlanta Rapid Transit Company can cross the tracks of the Southern Railway on Decatur Street, and that the Atlanta Railway & Power Company can cross the tracks of the Southern at Henderson's store, at the end of South Pryor Street. Both companies had been granted franchises which would carry them across the tracks of the Southern at the points named at grade crossing, and when the lines were being constructed with this end in view the steam railroad company filed petitions in each case for injunction. Temporary injunctions were issued pending hearings.

VENICE, ILL.—All connections have been completed and the power turned on the Venice, Granite City & East St. Louis Electric Railway. Cars are now running from Granite City via Venice to East St. Louis.

CHICAGO, ILL.—The Council has granted an extension of franchise, giving the Metropolitan West Side Elevated Railroad Company the right to extend its terminals on two branches, after a contest which defeated temporarily an amendment granting a surface franchise extension enabling the company to run its cars to the grade and continue as a surface line to Austin Avenue. The extension, as granted, enables the Metropolitan to compete with the Lake Street Elevated Railroad Company in the western suburbs. The ordinance grants a fifty-year franchise, the work of extension to be completed within two years. It grants the company the right to extend its Douglas Park branch, between Twentieth and Twenty-First Streets and Campbell and Western Avenues, to South Fortieth Avenue, and its Garfield Park branch at Forty-Eighth Avenue to Fifty-Second Avenue. The ordinance requires the company to proceed to the purchase or acquisition of a right of way within sixty days and to have the extensions completed within two years. A bond of $50,000 is required.

INDIANAPOLIS, IND.—The Indianapolis & Greenwood Electric Railway Company and the Indianapolis Electric Railway Company have reached an understanding in regard to the operation of the former company's cars over the lines of the latter company in the city proper, and a contract will be signed shortly. The franchise is for twenty years. The Greenwood Company is to pay the city $100 for every passenger car that is used regularly on the streets and $50 a year for every combination freight and passenger car. Fare is to be the same as that collected by the Indianapolis Street Railway, but no transfers will be granted. The Board of Works reserved the right to require transfers at the end of five years. Interurban cars are to stop at all crossings if passengers want to get on or off. The Greenwood Company objected to being required to maintain a warehouse, but the Board stood by the proposition. The Board will require that large freight be put off at the Belt Railway. The Greenwood Company will run cars west of Maryland Street, but will be allowed to use Washington Street as they leave the city.

AUGUSTA, MAINE.—Crescent Park, on the line of the Augusta, Hallowell & Gardiner Railroad, at Farmingdale, has just been opened to the public. It has been the aim of the landscape gardener who laid the park out to make the park rustic in appearance and to maintain its natural beauty. A dam has been built in a gully in the park, and the banks around the pond rise to a height of 50 ft. A rustic bridge has been built to span this stream and make a very pretty decoration. The park is lighted with electricity and the walks are covered with gravel. A stand has been erected on the banks of the river and from this band concerts are given.

MEDFIELD, MASS.—The Medfield & Medway Street Railway Company held a public opening of its line between Medfield, Medway and Franklin Center, June 27. In response to invitations of H. Gore & Company, of Boston, the contractors and builders, three special cars filled with street railway men, town and county officers, citizens and newspaper men, left Dedham at 12:15 over the Norfolk Western Street Railway. The run was all the way through a beautiful rural district, and covered sections of Dedham, Westwood, Dover, Walpole, Medfield, Millis, Medway and Franklin. The party was in charge of Edward S. Spring, superintendent of the road. The new road is 4 miles in length. The total cost of construction was about $240,000. Brill, Laconia and Newburyport cars are used. The car house, waiting-room and storage-battery buildings are located at Pond Plain, in Westwood.

TEMPLETON, MASS.—The Templeton Street Railway Company expects to have its new line ready for operation by Aug. 1. It was originally planned to have the line in operation by June 1, but unavoidable delays were encountered.

BOSTON, MASS.—A broken brake-chain on an inward bound car of the Boston Elevated Railway Company from Brookline to East Boston caused the car to jump the track at Roxbury Crossing, on Tremont Street, June 29, and dash into a house. Twenty persons were injured.

BAY CITY, MICH.—The Bay Cities Consolidated Railway Company has worked a complete transformation at Wenona Beach since the first of last month, and with the exception of the bath and boat-houses there is little left to identify the old place. The peanut stands have been remodeled and moved from their former sites and now occupy a row along the main entrance to the grounds. The café is an open building, fitted with electric lights and chairs and tables. A broad and very substantial sidewalk has been built to the boat and bath-houses and the walks around them widened. A number of cottages have been moved away and arrangements will be made for moving the remainder. The site of the old pavilion has been graded and a large portion of it sodded, while the remainder was filled with black earth and planted with flowers. Broad cinder walks start from the entrance of the grounds and connect the various buildings. The trees and bushes throughout the place have been trimmed, the grass cut, and everything is fast being made to look as neat as a pin. All the buildings have been painted white.

KANSAS CITY, MO.—The Kansas City, Liberty & Excelsior Railway Company has been incorporated, with a capital stock of $1,000,000, to construct a railway from a point in Clay County opposite Kansas City, Mo., through the town of Liberty to Excelsior Springs, on the eastern line of Clay County, a distance of 30 miles. The motive power of the road is not specified. Claud Hardwick, Charles H. Scott and Riley Bevins are among the incorporators of the company.

ST. LOUIS, MO.—The St. Louis County Court has granted the Wellston, Creve Cœur Lake & St. Charles Railway Company a franchise to construct an electric railway, which will connect with four steam railways and four other electric lines. The franchise designates a route beginning at Carsonville, where the St. Louis & St. Charles Electric Road connects with the St. Louis & Suburban, thence running along the Natural Bridge Road to a point of intersection with the St. Charles Rock road and going through Bridgeton. Another branch commences at the Missouri River, near the Burlington Railroad bridge, thence traverses southward through Crosskeys and Florissant, connecting there with the St. Louis & Suburban Railroad. From Florissant it continues southward to the crossing of the Wabash Railroad at Bridgeton; goes through Bridgeton and Palonville, connecting with the Midland Railroad. Extending southward, it enters the town of Mokeville and connects with the St. Louis, Kansas City & Colorado Railroad. Crossing this, the proposed line continues to Stephen's Grove, at Creve Cœur Lake. The entire line is to be constructed on a private right of way. The court provided that at the crossing of highways no more than 200 ft. of them be traversed. Ninety days was given the company to file a bond of $5,000 to guarantee compliance with the provisions of the franchise.

ST. LOUIS, MO.—An ordinance has been introduced into the City Council by the St. Louis Transit Company asking for permission to tear up some of

its tracks in the vicinity of the Fair Grounds and substitute a loop for lines centering there.

ST. LOUIS, MO.—The employees of the St. Louis & Suburban Railway Company are to have a club-room furnished and maintained by the company. The auditorium at 3919 Morgan Street is the place selected by Manager Jenkins. A pleasant feature of the innovation is that all reliefs of train crews will be made from the club-house, instead of at Sarah Street as heretofore. Baths are to be provided at the quarters, where the men can get rid of the heat and dust of their work when their runs for the day are over.

KANSAS CITY, MO.—During the Democratic National Convention, held here last week, the Metropolitan Street Railway Company maintained two information bureaus for the convenience of the delegates to the convention. The bureaus were in charge of men thoroughly familiar with the city and its surroundings, and were of great convenience to the visitors.

NASHUA, N. H.—Two cars of the Nashua Street Railway collided a few days ago. Several passengers were injured and one had her leg broken.

DUNKIRK, N. Y.—The Dunkirk & Point Gratiot Traction Company has completed and placed in operation its line between Dunkirk and Point Gratiot. The company is at present operating seven cars. The officers of the company are: L. F. Stearns, president; J. C. Haggett, vice-president and general manager; George A. Starr, secretary; A. J. Lenet, treasurer; L. F. Stearns, J. C. Haggett, Wm. Bookstaver, M. L. Hinman, E. R. Warner, A. J. Lenet, J. C. Karney, A. H. Marsh and S. F. Nixon, directors.

SYRACUSE, N. Y.—The Syracuse, Lakeside & Baldwinsville Railway Company has satisfactorily settled the difficulty between it and the village of Baldwinsville, and the tracks are being extended across the Seneca River and through Canal Street to the Delaware, Lackawanna & Western tracks in that village, thus completing the road under the terms of the franchise.

POUGHKEEPSIE, N. Y.—The village of Wappinger's Falls has begun action against the Poughkeepsie City & Wappinger's Falls Electric Railway Company to have the franchise granted the company in Wappinger's Falls vacated. The franchises were given seven years ago. Only the line to Poughkeepsie was built and operated. The village seeks to compel the forfeiture of the franchise for the other lines, on the ground of "non-user." The company seeks to hold the franchises on the ground that no public interest is affected thereby. If they are permitted to lapse there would be a loss, for since they were granted in 1893 the State Legislature has enacted a law prohibiting the granting of any further franchises for the construction of railroads in the old Boston Post Road. The company asserts that conditions of traffic do not warrant the building of the lines at present.

ROME, N. Y.—The Rome City Street Railway Company has placed an order with the Compressed Air Company, of New York, for the equipment of fifteen of its cars with the new type air motor.

BROOKLYN, N. Y.—It is said that the Brooklyn Rapid Transit Company has decided not to take to the Court of Appeals the right to charge 10 cents to Coney Island, provided a decision can be had on that question in the Appellate Division of the Supreme Court sitting in Brooklyn. This may put an end to McNulty's suit through the State Attorney-General to take away the franchise of the roads.

BROOKLYN, N. Y.—The Brooklyn Rapid Transit Company has arranged to reduce the number of trips on all the lines, except those running to the seashore. Cars will run just as frequently during the rush hours, however, the reduction only operating during the middle of the day and late at night.

SYRACUSE, N. Y.—The valuation of the franchises of the Syracuse Rapid Transit Railway Company has been placed at $1,262,000 by the State Tax Commission.

NEW YORK, N. Y.—Commissioner Shea, of the Department of Bridges, has reported to the Mayor that the receipts of the Brooklyn Bridge for the year ending Dec. 31, 1899, were $435,208.76, and expenditures $284,507.19, leaving a profit of $150,701.57. The electric and elevated companies paid $159,593.30 for the privilege of running cars on the structure.

BINGHAMTON, N. Y.—The Stowe Driving Park, in this city, has been purchased by the Binghamton Street Railroad Company backed by New York capitalists. The property brought $22,617.

BUFFALO, N. Y.—The International Traction Company contemplates making a number of important improvements in its park at Olcott, and has plans for remodeling the grounds, drawn by Frank M. Blaisdell, of Boston, who laid out Norumbega Park at Boston, and Merrymeeting Park at Brunswick, Maine. The plans for the improvements of the park are elaborate. All of the buildings will be of rustic design. The principal building outside of the hotel will be a theater. The auditorium will be covered in for the protection of the audience, and the stage will be open to the sunlight. Nature will supply the scenery. The lake and the grove will be in plain view of the audience, and this feature will also allow of free ventilation and comfort. J. W. Gorman, of Boston, will furnish the attractions at the theater, and a new cast will be presented each week. The present hotel on the grounds will be enlarged and greatly improved and made to conform with the rustic surroundings. The hotel is of brick, but the new addition will be a frame structure and will extend to the lake. One of the largest buildings will be the pavilion, which will be 200 ft. long. In it will be a dance hall, a restaurant and a shelter building combined. It will be provided with open sides fitted with slide windows, which will afford protection in rough weather. There will be bath houses, toboggan slides, boat houses and merry-go-rounds galore, and all the features of a summer resort will be found. One of the contemplated improvements to the grove is the erection of a sea wall for the protection of the grove and the beach. It will be built of cement and will be 8 ft. high. A dock will be built out into the lake, so that boats can land and swimming and fishing be enjoyed from it. Mr. Ely said during the course of the interview that eventually the company would make an effort to have a lake excursion boat line touch at Olcott.

STATEN ISLAND, N. Y.—The waiting-room and transfer station of the Midland Electric Railway Company at Concord was destroyed by fire July 2. The loss was between $3,000 and $4,000.

LONG ISLAND CITY, N. Y.—The New York & Nassau County Railway Company, which was incorporated early this year to construct an electric railway from Queens Borough line near Queens to Hempstead, has elected the following officers: Joseph Bermel, president; P. J. Marra, vice-president; E. J. McKeever, treasurer; W. L. Woodill, secretary. The directors have adopted a resolution requesting the State Board of Railroad Commissioners to set a date for a hearing upon an application for permission to build the road.

ZANESVILLE, OHIO.—The Zanesville Electric Railway Company has awarded prizes to the motormen and conductors who have had no accidents during the past six months. Thirteen men secured prizes. Ten dollars was given to the motormen and five dollars to the conductors.

COLUMBUS, OHIO.—The Council has passed an ordinance granting the Grove City & Green Lawn Street Railway a franchise for the construction of electric lines on Mound and McDowell Streets to connect with the lines of the Columbus, London & Springfield Railway Company. This gives the Grove City & Green Lawn entrance to the heart of the city.

COLUMBUS, OHIO.—The Columbus, London & Springfield Traction Company has filed its acceptance of the ordinance granting the company a franchise over the National Pike. The company paid $2,500 for the grant, and has deposited $5,000 to insure the construction of the road. The franchise is for a period of twenty-five years. Active preparations are being made to begin the construction of the road at once, and ties are being distributed along the route.

MARIETTA, OHIO.—The City Council has passed an ordinance granting the Marietta Electric Company a franchise for the extension of its line (known as Route 2) upon the county road known as Green's Road, from the easterly corporation line of Marietta to the northerly end of Duck Creek Bridge. The grant is for a term of twenty-five years, and will be subject to the terms and conditions contained in the ordinance establishing Route 2.

DAYTON, OHIO.—Local authorities have commenced proceedings to force the Southern Ohio Traction Company and the Dayton, Springfield & Urbana Electric Railway Company to put safety fenders on all cars operated within the city.

CHILLICOTHE, OHIO.—The Chillicothe Electric Railroad, Light & Power Company has removed its office to No. 22 West Second Street.

WORCESTER, MASS.—Opposition to the construction of the Worcester, Leominster & Fitchburg Street Railway Company appears to have disappeared, and the company is now preparing to present applications for franchises in Worcester, West Boylston, Sterling and Leominster.

COLUMBUS, OHIO.—The street railway employees here are donating 25 cents each per month to be distributed to the city poor at Christmas time.

SALEM, OHIO.—The reported sale of the Alliance Gas & Electric Light Company, the Alliance and Salem street railways and the franchise for the Alliance-Salem Road, to an Eastern syndicate is denied by officials of the companies.

CINCINNATI, OHIO.—The Millcreek Valley Street Railway Company has placed an order for twenty cars with the St. Louis Car Company.

POTTSVILLE, PA.—Two cars of the Pottsville Union Traction Company collided between Schuylkill Haven and Adamsdale on July 5. Twenty passengers were injured by the collision.

WILKESBARRE, PA.—On July 8 two cars on the Duryea & Scranton line collided, one man being killed and ten injured. The dead man was a motorman of one of the cars, who heroically remained at his post in an endeavor to stop the car, and was crushed. The accident is said to have been caused by a switch which had been mislaid by some boys.

HARRISBURG, PA.—The annual meeting of the Harrisburg Traction Company will be held July 17. The most important matter to come up at this meeting will be the reports of the year and the election of a board of directors.

PHILADELPHIA, PA.—The Philadelphia *Financial News* gives the following list of properties acquired or shortly to be taken over by the Consolidated Electric Company: Kennett Electric Light, Heat & Power Company, Kennett Square, Pa.; Haverford Electric Light Company, Haverford, Pa.; Oil City Electric Company, Oil City, Pa.; Franklin Electric Company, Franklin, Pa.; Franklin Gas Company, Franklin, Pa.; Titusville Electric Light & Power Company, Titusville, Pa.; Armstrong Electric Company, Kittaning, Pa., Kittaning & Ford City Street Railway Company, Kittaning, Pa. On Aug. 1 the Consolidated Electric Company will operate the following additional properties: Wayne Electric Light Company, Wayne, Pa.; Coatesville Electric Light, Heat & Power Company, Coatesville, Pa.; Doylestown Electric Company, Doylestown, Pa.; Doylestown Gas Company, Doylestown, Pa.; Bristol Electric Light & Power Company, Bristol, Pa.; Bradford Electric Light & Power Company, Bradford, Pa.; Warren Electric Light Company, Warren, Pa.; Warren Gas Light Company, Warren, Pa.; United Light Company, Uniontown, Pa.; Steubenville Gas & Electric Company, Steubenville, Ohio; Steubenville Traction Company, Steubenville, Pa. The Consolidated Electric Company was organized under the laws of New Jersey a few months ago, with an organized capital stock of $4,000,000. The officers of the company are: William F. Eidell, president; Stanley R. Ketcham, vice-president; C. E. Gouert, secretary; Charles F. Lamb, treasurer.

CHATTANOOGA, TENN.—The Chattanooga Electric Railway Company and the Chattanooga, Rome & Southern Railroad have entered into an agreement by which cars of the former will be run over the lines of the latter to Chickamauga Park.

Organization of the New England Street Railway Club

A number of street railway superintendents, as well as others interested in street railways, was held on Wednesday evening, July 18, 1900, at Young's Hotel, Boston, to discuss the arrangements for an outing some time during the month of September, to include all who are in any way interested in street railways, taking in all the New England States. There seemed to be a general feeling among the superintendents that such an outing would be a grand success, and of much mutual benefit, if all would take an interest in it. The meeting was a most enjoyable affair. There were about thirty-five gentlemen present, and it was decided to form the "New England Street Railway Club," the membership of which would be composed not only of operating railway men, but of all persons interested in street railway work. The following officers were elected: President, H. E. Bradford, Marlborough Street Railway Company, Marlborough, Mass.; vice-president, L. H. McLain, Newton & Boston Street Railway Company, Newtonville, Mass.; secretary, R. H. Derrah, Boston, Mass.; treasurer, George H. Burgess, Leominster & Clinton Street Railway Company, Leominster, Mass. The executive committee consists of the officers and F. G. L. Henderson, Newton Street Railway Company, Newton, Mass.; E. E. Potter, Union Street Railway Company, New Bedford, Mass.; J. F. Whetles, Boston, Mass.; W. G. Meloon, Portsmouth; Kittery & York Street Railway, Portsmouth, N. H., and D. F. Burritt, Palmer & Munson Street Railwaypany, Palmer, Mass.

As the club is formed for social purposes only, it will be quite distinct from the Massachusetts Street Railway Association, and will not interfere with the latter in any way. A meeting of the club will probably be held within a month to arrange for an outing some time during September.

Terrible Accident at Tacoma

An accident, worse than the Pecks Mills disaster of last summer, and probably the worst in the history of electric railroading, occurred at Tacoma, Wash., on July 4. A car crowded with passengers from South Tacoma and Spanaway Lake jumped the track at a high bridge crossing a gulch at Dehn and D Streets, falling a distance of 100 ft., and striking on its roof. The heavy motors and trucks crashed through the floor of the car, killing thirty-six persons and injuring about sixty. Other passengers would probably have suffered similar fate had they not jumped from the car when they saw that an accident was not to be averted.

The Chicago Street Railway Commission Recommends a Modified Form of Municipal Ownership

The Railway Committee of the City Council has declared in favor of a modified form of municipal ownership of street railways, and in favor of a form of compulsory arbitration in labor disputes, which would make street railway strikes impossible. The commission agrees that street railway strikes are such an interference with public business that the municipality is justified in taking steps to prevent them. While no plan was selected formally, the opinion was that all grants of franchises should have a clause providing for compulsory arbitration. The commission committed itself to municipal ownership so far as the tracks and other parts of a street railway plant actually in and a part of the street are concerned. It did not decide in favor of municipal ownership of rolling stock, power houses and other parts of the plants, and municipal operation was not considered at all.

Fourth of July Traffic and Accidents

July 4 was, according to the traffic figure kept by the street railway companies in the larger cities, a record breaking day in the number of passengers carried. Companies all over the country enjoyed a large increase in traffic, and former records for carrying passengers were broken in many cities, including Albany, Troy, Kansas City and Buffalo. The day was also eventful in the way of accidents, the worst of which occurred at Tacoma, where thirty-six persons were killed, and about sixty injured, and at Webster, Mass., where two were killed and many injured. Accidents not so grave as those mentioned above occurred at Dayton, Cincinnati, Detroit and Kansas City.

The Situation in St. Louis

The strike situation at St. Louis remains unchanged. The company is operating its cars regularly, and but for the appearance of the 'buses, run by the strikers, there is no indication that a strike is on. So far there have been very few attempts at violence. One man was killed, however, by an employee of the Transit Company,

whom he attacked on Saturday, and another was seriously injured. On July 17 the citizens' arbitration committee sent letters to President Whitaker and the directors of the company and Chairman T. S. Edwards, of the grievance committee, formally requesting that they submit the differences between the company and the strikers to arbitration.

Besides the difficulties with its employees the company has also to prepare to defend quo warranto proceedings against it by the Attorney-General, who prays for the revocal of the charters of the St. Louis Transit Company, United Railways Company and the National Railway Company, on the ground that the United Railways Company has not conformed with its charter and that it is a party to a scheme to create a street railway monopoly in St. Louis, as shown by its lease of its properties to the St. Louis Transit Company, a corporation apparently formed to assist in the formation of the alleged monopoly. The petition alleges over-capitalization and violation of the State and Federal constitutions.

Mr. Louderbach Resigns from the Lake Street and Northwestern Elevated Roads of Chicago

D. H. Louderbach resigned last week as president and director of both the Lake Street Elevated Railroad and the Northwestern Elevated Railroad, of Chicago. Howard Abel, secretary and treasurer of the Lake Street Elevated Railroad, was elected president of that company, and Harvey T. Weeks was elected to succeed him on the board. William V. Griffin succeeds Mr. Abel as secretary and treasurer of the company. Louis S. Owsley has been elected president of the Northwestern Elevated, to succeed Mr. Louderbach. Mr. Abel is considered to be well qualified to perform the duties of his new position, he having been connected with the Northwestern Elevated, the Union Elevated and many of the surface lines now embraced in the Consolidated Traction Company, and also having a prominent position in the management of the Lake Street Elevated during Mr. Louderbach's term as president. Mr. Abel is thirty-two years old. Mr. Owsley's experience began several years ago as treasurer of the West Chicago Street Railroad. He is thirty years old.

Superintendent Rounds of the Metropolitan Street Railway Resigns

Frederick D. Rounds, general superintendent of the Metropolitan Street Railway Company, and general manager of the Third Avenue Railroad Company, of New York, has resigned. Mr. Rounds' resignation is said to have been due to marital troubles, and it is announced that he will leave the city and embark on a business career elsewhere. Mr. Rounds was born in Watertown, N. Y., in 1864, and came to New York twelve years ago. He became interested in the work of the Young Men's Christian Association, and was later elected secretary of the West Side branch of that association. Later he became secretary of the Broadway & Seventh Avenue Railroad. When Mr. Vreeland was elected president of the Metropolitan Street Railway Company in 1893 he appointed Mr. Rounds as his secretary. Through perseverance and attention to duties he was gradually advanced to the position which he has just resigned. The position held by Mr. Rounds has been abolished, and the duties will hereafter be performed by Oren Root, Jr., the present assistant general manger. T. A. Delaney, who was superintendent of the Second Avenue division of the Metropolitan system, has been advanced to the newly created position of superintendent of transportation. J. J. Shea, who was Mr. Delaney's assistant, has been elected to succeed Mr. Delaney.

New York Roads to Fight the Franchise Tax Law

The railroads of New York City are preparing to fight the franchise tax law, and have secured writs of certiorari against the State Board of Tax Commissioners to review the assessments made for this year under the new law. In each case it is set up that the assessments are wholly illegal, the contention being that the franchise tax law impairs the obligations of the contracts under which the franchises were acquired and so is in contravention of the State and federal constitutions. The writs are all returnable the first Monday of October.

The Third Avenue Railroad Company was first assessed by the State Board at a valuation of $11,886,200. On aplication for a correction of the assessment it was reduced to $11,247,712. Aside from the constitutional question raised it is contended that the assessment is based on an overvaluation of $10,483,878.

The Forty-Second Street, Manhattanville & St. Nicholas Avenue Railway Company was assessed at $2,418,900, but the State Board reduced this on a hearing to $2,047,149. The company says the reduced assessment is too high by $1,577,853.

The assessment of $2,320,000 made against the Union Railway Company (Bronx) was reduced to $1,702,278 by the Tax Board, but the company says this an overvaluation by $1,117,278. The Union Railway Company (Manhattan) was assessed at $50,000, but that was reduced to $46,000. It is urged that the reduction should be to $5,000.

The Dry Dock, East Broadway & Battery Railroad, which got the State Board to reduce its first assessment from $2,708,000 to $1,378,767, wants the valuation put at $100,000. The Southern Boulevard Railroad Company had its assessment of $211,680 reduced to $155,395 by the State Board. It says that this is an overvaluation of $67,395. The Westchester Electric Railway Company was assessed $183,320. This was lowered to $115,800 and the road wants a further decrease to $65,300. The Manhattan Railway tax is based on a valuation of $46,127,000. The company asks for a reduction to $11,720,239.

Employees of the Chicago Union Traction Company Secure an Advance in Wages

On July 10 the Chicago Union Traction Company notified the employees of its North Side lines in an official circular that after Aug. 1 they would be paid by the hour at the same rate now in force on the West Side. No employee will receive less than $1.50 per day. The circular urges the men to stricter attention to their duties to the company and to the public. The circular follows in part:

"Chicago, July 10, 1900.—To the Employees of the Chicago Union Traction Company—Gentlemen: In the management of great interests like the Chicago Union Traction Company, and in order to successfully meet all the requirements of the public, it is necessary that the management and the employees thoroughly understand each other. With this object in view, it is my desire in this communication to call your attention to the many criticisms which are being passed upon your actions, principal among which are the alleged ungentlemanly treatment of passengers and general carelessness which results in accidents.

"Before taking unnecessarily harsh measures it is the desire of the management to better present conditions and also retain the employees who are now in its service; therefore I especially and most earnestly request that conductors, gripmen, motormen and all other employees so conduct themselves in every act that their conduct toward the public may be such that it will commend both the employees and the management to the entire community. In other words, an employee of this company must be a gentleman under any and all circumstances.

"In reference to accidents, I wish to say that there are conductors, gripmen and motormen who have been in the service of this company for a number of years, and have never had a serious accident, at the same time running upon streets where others meet constantly with annoying and expensive accidents, caused by lack of attention and forethought to see impending danger.

"I wish to state most emphatically that avoidable accidents must be stopped. I am of the opinion that this can be brought about without the dismissal of men, and call upon you to demonstrate, by your actions, commencing this day, that accidents may be materially reduced. If this cannot be accomplished by mild measures, the management will be forced to act more severely.

"Be gentlemanly at all times. Remember that deportment is considered in the general standing of an employee, and neatness of person and attire is as much necessary to success in the railroad business as elsewhere. Elderly persons and women with children should have assistance when getting on or off your car. Remember that in the railroad business, as well as elsewhere, gentlemanly deportment, neatness of person, and good common sense will sooner or later meet with their proper reward.

"As further evidence of the close relations existing between employer and employee, the management has concluded (at a time when no demands are being made) to pay all trainmen in the service of the Union Traction Company a uniform rate by the hour. On and after the first day of August, 1900, the employees of that part of the system known as the old North Chicago Street Railroad will, if they prefer this system of payment, receive the same rate of wages as now paid to those of the West Side lines of this company, as follows: Gripmen, 23 cents per hour; motormen, 21 cents per hour; cable grip-car conductors, 23 cents per hour; cable trailers and electric car conductors, 21 cents per hour.

Yours very truly,

J. M. Roach,

"President and General Manager."

The Berlin Street Railway Strike

[*From Our Regular German Correspondent.*]

The strike which occurred recently on the lines of the Grosse Berliner Strassenbahn, though of shorter duration than that in St. Louis, seriously crippled the service of the company while it lasted. Of the 5200 employees of the company, 4800 went out. Soon after the ordering of the strike, on May 18, the former employees and their sympathizers commenced their interference with the operation of the company's cars. Numerous attempts at violence are reported and the strikers resorted to the most cowardly means to do damage to the company's property and injure its new employees. These latter soon refused to do their duties, as they were no longer certain of their lives, but as soon as operations were stopped, there were no more demonstrations by the mob. The officials of the company announced their position in a circular, which was sent to the press, and which contained the following statements:

"While the directors of the road attempted to continue the operation of the road in the best possible manner with new men the strikers endangered the lives of these men by systematic attacks, and interfered with traffic by damaging the company's property, placing stones on the tracks, and unharnessing the horses. This plainly shows that the leaders of the strike have no intention of arriving at an amicable settlement with the officers of the company, but are desirous of forcing matters to extremes by violent attacks without regard to the lives and convenience of the traveling public. The directors, on the other hand, have concluded to meet the demands of the strikers in a peaceful manner. They have promised to pay the motormen and conductors M. 90 per month when they enter their employ. These wages are gradually increased during the first ten years to M.110, and as the men continue in the company's service to M.120. This is in addition to all extra earnings, giving them their uniforms free, promising them a Christmas present, trip tickets and money in case of sickness. The questions regarding the number of working hours and division of time were also discussed with the representatives of the employees, and here again the company met the demands of the men. It should be stated in particular that each man was to get off one day in each week, and one Sunday in each month, and full pay was to be given during vacation days to all men who had served for three years."

It is to be regretted that the principal Berlin newspapers took so adverse a stand toward the company, which does not seem to be liked any too well by the general public. But this is the case with nearly every large railway company, no matter how well it tries to serve the public. The papers, for example, resented the statement of the company that the strikers used extreme measures to force the issue, and expressed the belief that the sympathizers of the strikers should be blamed for the damage inflicted. It seems certain, neverthless, that it must have been the strikers themselves, as familiarity was shown with car construction and equipment by the way in which the cars were dismantled and the brakes, the contact switches, controllers, etc., removed. Even if the strikers did not actually do this destructive work themselves they certainly must have instructed their accomplices.

It may further be remarked that the police were very slow in making their appearance and protecting life and property. In one of the conferences held between the police commissioners and the directors of the company, in the presence of a member of the imperial railway ministry, to discuss the question whether the company had done everything in its power to avert the strike, and what might be expected from a large railway company, it was decided in the affirmative, and the concessions made by the company were deemed sufficient, such as the payment of 40 pfg. per hour overtime, instead of 25 pfg., as heretofore, and this was increased to 50 pfg. per hour by the directors, thus doubling the former rate.

The magistrate also had a conference with the city's traffic association to discuss the question of the pensioning of old, incapacitated street railway employees. The company, it should be stated, is about to establish a pension fund for all its employees, to which the latter and the directors contribute equally. The employees have their dues deducted from their monthly salaries, while the directors contribute their share at the end of the fiscal year. The question at issue now is as to who is to decide when an employee is entitled to a pension on account of disability. The directors claim this right for themselves, while the employees assert that they should have a right to share in this decision, because they contribute equal dues. The magistrate agreed with the employees, and this latest demand has been submitted to the company, namely, that the board of trustees of the pension fund shall be composed of delegates chosen by the employees and by the directors, who shall decide the question of eligibility to a pension.

The strikers chose this time for making their demands, as they knew the density of the traffic during the pfingst holidays, and the loss a strike would mean to the company during that time.

On Sunday, May 20, traffic was resumed with sixty cars, and was continued on seven main lines, until 7 p. m. The employees consisted of men who had stood by the company, and new hands which applied in very large numbers. Each motorman was accompanied by a guard, and ample preparations had been made by the police to avert any violence on the part of the strikers. The latter left Berlin during the early morning hours, and assembled in the suburban towns.

The demands of the strikers were as follows: Conductors and motormen to start with wages of M.90 a month, which is to be increased M.5 each year until a maximum of M.130 is reached, that is after eight years of service. A working day to consist of nine hours for motormen, of which only eight and one-quarter should be working hours, there being one or two periods of rest, three-quarters of an hour in length. No trip should take longer than one and one-half hours, and after each trip there should be a rest of at least twelve minutes at the terminal points. Should the men demand extra pay on Sundays or other days with heavy traffic, the rate shall be 60 pfg. per hour. The conductors demand ten working hours and the same maximum hours and other conditions asked for by the motormen. The latter shall be permitted to draw mileage (trip money) as they did formerly, which amounts to about M.15 each month, while the conductors shall be permitted to receive tips. Conductors and motormen are to receive ten days vacation each year, and one day off duty each week, which must be a Sunday once every four weeks. All these "off" days shall be paid for in full. They further demand that a married man must be notified three months in advance if he is to be transferred to another territory, and a single man four weeks in advance. This is demanded because formerly it was often necessary for a man, who had been transferred to a distant portion of the system, to travel an hour or more before he reached his home. The men base their claims for higher wages and shorter hours on the fact that the introduction of electricity demands greater care and attention on the part of the employees, and that the motormen are in constant danger of being imprisoned, the penalty in Germany for a collision. For that reason the motormen are steadfast in their demands. In addition to the above danger they claim that their health and lives are imperiled frequently on account of the reckless driving of coachmen and the high speed of the cars.

This recklessness on the part of the Berlin drivers is evidenced very clearly in the official report of the Traffic Commissioner for 1898. According to these statistics 2517 accidents to persons are due to horse and electric cars, seven of which were fatal, 145 serious and 1048 slight injuries. The omnibus service is responsible for 163 accidents, seven fatal, forty-two serious and seventy-six slight injuries. Other vehicles, such as butcher and beer wagons, caused 2996 accidents, forty-two of which were fatal, 463 serious and 1559 slight injuries. One thousand and ten accidents are due to bicycling, of which two were fatal cases, thirty-eight serious and 497 slight injuries. A total of sixty-six persons were killed in these ways in 1898, and in 1899 seventy-six persons. It must not be forgotten that the streets are wide and well paved, while in other large cities, such as London, Paris, Vienna, etc., the drivers are frequently handicapped. Many attempts have been made to remedy this evil, and it has lately been proposed by Mr. von Ploetz to establish a training school for drivers, which should be supported by the city, and where each newcomer must satisfy the police department that he is capable of managing his team before he is permitted to appear on a seat of a conveyance in the streets of Berlin.

On Monday, May 21, the service was continued in the same manner as on Sunday. On Friday, Saturday and Sunday the strikers had held meetings which were attended by 4000 men, and it was decided to ask the Mayor of Berlin, Mr. Kirschner, to act as arbitrator. The latter accepted the office, and advised the men to go to the directors of the road and ask them to sanction their selection. This was agreed to, and a meeting was held at the City Hall, which lasted until 4:30 p. m. An agreement was finally reached, and the strike was declared off, the following conditions having to be fulfilled:

The pension fund is to be managed by a board consisting of delegates chosen by the employees and directors. The salaries of the motormen and conductors at the beginning to be M.85, after a six months trial M.90, after three years' service M.95, after ten years' service M.100, after fifteen years M.115, and after twenty years M.120. The employees are to get four days off duty each month, and every seventh day must be a Sunday. The maximum number of hours for conductors is eleven, for motormen nine. Overtime is to be paid for at the rate of 50 pfg. per hour. At each depot there will be representatives of the men, who will look after the welfare of the employees and settle any differences which may arise between them and the officials of the company. All these

agreements were ratified by the strikers, and the strike was declared at an end at 3:30 p. m.

As the general public evinced great sympathy with the strikers at the beginning of the disturbance, without having any knowledge of the income of the men and the prevalent conditions, as well as the new arrangements entered into by the employees and the company, it might be well to point out by actual figures how great an influence the moneys paid to employees have on the profits of, and therefore the dividends paid by, the company. The desire for more wages is becoming epidemic throughout Germany, and for that reason this question is one of particular interest and importance.

In looking over the 1899 report of the company we find the following items in the chapter dealing with salaries: Five thousand three hundred and fifty-seven persons were employed, against 5014 in 1898. The increase of 343 persons is due to the extensions of the electric roads.

1. The wages of these 5357 employees during 1899.....	M.5,136,908
2. For work on extensions, including the care of depots, roads, maintenance of horses and wagons, etc.	913,455
3. Payment for living quarters for watchmen and depot master	11,325
4. Uniforms supplied free to the men and their repairs	223,469
5. For sick and disabled employees.....	42,555
(To sick persons the sick fund pays two-thirds of their salary, and if they have been in the service of the company for three years, the latter adds the other third; this amounted to 38,000 marks, which is included in the above item.)	
6. At the general meeting there was allowed for aid to employees.....	50,000
7. The company paid into the sick fund.....	45,200
8. The company paid into the treasury of the accident insurance company for the benefit of the employees.	29,000
9. For insurance of old and crippled employees.....	41,000
Total	M.6,493,307

This gives an average income for each man of M.1212.11 or M.101 each month, which cannot be considered as insufficient or starvation wages, in view of German conditions. Besides their wages, the conductors, and to a lesser degree, the motormen, have a small income in the way of tips, which ought not to be omitted from consideration simply because it does not come from the company. The latter could easily charge from 5 to 10 pfg. for each basket or package if it would so elect, instead of permitting the conductors to pocket such fees. It is difficult, however, to estimate this income because the employees are apt to underestimate it when asked for a report. It might be fair to assume that each tenth passenger gives the conductor a 5-pfg. tip. In 1899, 180,000,000 persons were carried on the lines of the Grosse Berliner Strassenbahn; a tenth of this would give 18,000,000 5-pfg. pieces, or M.900,000. This is divided among the 1688 conductors, who give some to the nineteen chief conductors and 1558 motormen, a total of 3265. This would give each man M.275.65, which, added to the above average of M.1212.11, gives a total yearly income of M.1487.76. The beginners, of course, have less income, but in time it reaches this sum. Thousands and tens of thousands of Berlin workmen have less income than this, and many of those who do receive it do not have steady work,—surely not a life job, as is that of the railway employees. It is hard, therefore, to find a real cause for striking, but let us look at the new conditions.

The wages at the beginning have been increased from M.80 to M.85; after six months this is raised to M.90, etc., as stated before, until a maximum of M.120 is reached after twenty years' service. The former maximum was M.100 per month. The switchmen, roadmen, car cleaners, stablemen, etc., receiveM.3, and after some service M.4 per day. The "Kilometer money" of 50 pfg. per day for electric and 35 pfg. for horse service remain as before. Hours utilized for instructing the men are reckoned as overtime. Any employee pressed into military service for practice work will receive full pay.

The increased cost of the service to the company over what formerly obtained, consists of:

1. The increase of wages of from M.5 to M.20.

2. The shortening of the working day by two hours. This necessitates an increase of the force.

3. The establishment of the pension fund. This expense will probably not be less than M.50,000 each year to the company; in 1899 claims amounting to M.100,000 were submitted.

Summing these items up, we find that the salary increase for 3265 men amounts to M.489,750 each year. Adding to this an increase of M.30,000 for the other employees, there is a total increase of about M.520,000 in wages account. The shortening of hours will probably mean a 10 per cent increase in the number of men employed, or about 400 men, at M 1600 a year, making a total of M.640,000. The amount paid into the pension fund might be estimated at M.50,000 per year.

These three items give a yearly increase of M.1,010,000. The company's estimate was about M.1,000,000, showing the above calculation to be about correct.

The company's balance sheet showed a profit to be divided among stockholders of M.4,646,250, or for 44,250,000 shares, a dividend of 10.5 per cent. Subtracting from this the million mark increase in salary, there will be M.3,646,250 to be divided next year.

But in addition to this, the city, in lieu of extending the franchise until 1945, has asked for additional payment from the company. In 1899 the latter paid M.1,656,434, but in the future M.2,000,000 will hardly be sufficient. It is possible that the increased traffic and the cheaper electric service will more than make up for this increase, though this seems doubtful. Besides, the capital was increased last November by M.22,875,000, so that the profits must be divided among M.67,125,000 instead of M.44,250,000. The above M.3,646,250 would thus only produce a 5.43 per cent, instead of a 10.5 per cent, dividend. In fact, large dividends are a thing of the past; from 1890-1895 a dividend of 12.5 per cent was paid, then 15 to 16 and 18 per cent. In 1899 it was 10.5, the lowest in the entire decade. The stockholders have therefore lost over 100 per cent on the exchange, as the shares were formerly worth between 300 and 400, and now are only rated at 227. It is to be hoped, however, that if electricity is introduced on the entire road the showing will be much improved.

On the whole, it may be said that the company easily controlled the strike situation, as cars were run nearly uninterruptedly during the day time, and 22,000 persons applied for work under the old conditions. The victory, however, also is a significant one for the "Social-democracy," which is responsible for the strike. The 4000 employees have now formed an association which is in the hands of social-democratic leaders, and each man pays for social-democratic purposes 20 pfg. per week, or a total for all the men of M.41,600 per year. This may be termed the campaign fund for the next strike.

The success of the Berlin strikers has caused the employees of the Hanover, Cologne and Copenhagen street railway companies to demand higher wages. The Hamburg company had already promised its conductors an increase on April 1, which was a most fortunate circumstance and is probably responsible for the fact that Hamburg, where conditions are similar to those in Berlin, is the only large German city where no strike has taken place. Never before, however, has it been so clearly shown as by this strike how incapable the police force in German cities is to

Test of the Power Plant of the Buffalo Street Railway*

R. C. CARPENTER AND H. J. RYAN

The power plant of the Buffalo Street Railway was tested the latter part of the last term by the department of experimental engineering. The test was made at the request of R. E. Danforth, the superintendent of the Buffalo Railway Company, to ascertain the economy of the station when operating under various conditions. On account of the character of the power available at Buffalo, the test is one of peculiar interest. A large portion of the power is obtained from a steam plant, and a minor part from the water power at Niagara Falls. A storage battery of 272 cells 3000 amp.-hour capacity is also employed to absorb current during the time when the capacity is in excess of the demand and to give out current when the reverse condition exists.

While the plant is not larger in aggregate horse power than others which have been tested at various times by students in the course in mechanical and electrical engineering, yet on account of the number of units and the varied character of the apparatus employed, it required more apparatus and more help to successfully conduct the test than any before undertaken in connection with the Sibley College work.

In order to test the plant under various conditions of operation, it was necessary to operate it continuously for ninety-six hours. This condition made it necessary to have two shifts of observers. In all somewhat over ninety men from the junior and senior classes took part in the various tests as assistants and observers.

In the organization of the test, Professor Carpenter assisted by Professor C. R. Jones and Austin Burt had charge of the mechanical test, including boilers, engines and pumps, and Profes-

* From the *Sibley Journal of Engineering.*

sor Ryan, assisted by E. L. West and G. S. Macomber had charge of the electrical portion of the test. For the purpose of working up results and putting the records of the test in form, the work was divided into three sections and assigned to the following members of the senior class for theses.

1. The boiler section, J. J. Cuyle and L. Morgan.

2. The engine section, Austin Burt, J. V. McAdam, A. Englert, S. E. Smith, C. B. Holden, W. C. Dalzell.

3. The electrical section, G. S. Macomber, Charles R. Scott, R. H. Dearborn, J. M. Gilchrist, G. B. Woodhull, W. L. Cook, J. E. Hess.

The editing of all the mechanical and electrical results was undertaken by Mr. Burt and Mr. Macomber. The other gentlemen devoted their time to the detailed description of special features of the plant and to a discussion of the results.

A considerable portion of this abstract is taken directly from the thesis of Messrs. Macomber and Burt.

OUTLINE OF THE TEST

Equipment—The system of the Buffalo Railway Company is operated under three conditions of power distribution as follows:

1. By steam, operating 10 units, three 1000-hp vertical cross-compound D. C. engines, six 500-hp vertical cross-compound belted engines, one 250-hp horizontal cross-compound Ball engine belted.

2. By Niagara Falls power operating four 500-hp rotary converters.

3. By storage battery operating through a booster.

OBJECT OF THE TEST

The object of the test was to determine the following:

1. The relative value of the three conditions of operation.
2. The economy of the boiler plant.
3. The economy of the engines.
4. The economy of the electrical equipment.
5. The various factors in the operation of the entire plant.

The first it was proposed to accomplish by making three twenty-four-hour runs as follows:

a. Under normal conditions as operated every day, *i. e.*, with full quota of Niagara power, with as many engines as the load required, and with battery in normal service.

b. Eliminating Niagara Falls power and operating with engines and battery alone.

c. Eliminating the battery, operating with engines and Niagara power only.

The second was to be determined by a complete boiler test.

The third, by a complete engine test.

The fourth, by a thorough test of the electrical equipment.

The fifth, to be deduced from the results of the other tests.

The Test as Actually Carried Out—Everything was in readiness and the signal to start the test was given promptly at 11:00 o'clock a. m., Feb. 28, 1900. All went well until about 5:30 p. m., when an unexpected disturbance occurred just at the peak of the load. Owing to the disturbing influence thus introduced it was decided to call this run a preliminary one and make another normal run.

The actual test runs were as follows:

Run "2." Operating under normal conditions.
Run "3." Eliminating Niagara power.
Run "4." Eliminating the battery.

Everything ran along smoothly to the end of the test in spite of the fact that a terrific snow and wind storm prevailed for the greater part of the first three days.

It is a matter for which Sibley College should be congratulated that the largest test, of this character, in the history of engineering was so successfully completed without a single accident, either to the ninety students conducting it or to the valuable machinery so generously placed at their disposal.

The Boiler Plant.—The boiler plant consists of eighteen boilers, two of which are of the Scotch marine type, the remainder are water-tube boilers built by Babcock & Wilcox. The boilers are all set over Roney automatic stokers and are supplied with coal from a traveling car mounted on overhead track. The total boiler horse power has a rated capacity of 5080. The general results of the boiler test are shown in the following tables, each run being twenty-four hours in length:

Pressure	Run 1	Run 2	Run 3	Run 4
Barometer, inches mercury	29.13	28 73	29.08	29.40

THE ENGINE SECTION

The engines are numbered consecutively from 2 to 11, as shown by the table. A complete description of the details of the engines may be found in the thesis of Messrs. McAdam and Scott.

The Indicators.—There were thirty-eight indicators in use on the test, four on each engine with the exception of No. 3, which was provided with three-way cocks, and, therefore, with only two indicators. They were for the most part in excellent condition and stood the long strain remarkably well. The reducing motion was of the lever brumbo type and was carefully overhauled and put in good condition for each engine.

The Indicator Cards.—Metallic cards were used exclusively. In all 7344 cards were taken. Sample cards from each engine taken at 6 p. m., March 3, are shown in the thesis of Burt and Macomber.

IHP Data and Results.—The cards were all carefully integrated, computed and checked, and they are tabulated in the Burt-Macomber thesis. A comparative column of ehp with the combined engine and generator efficiency is shown in the same tables.

Table of Averages.—In this table are shown, in the Burt and Macomber thesis, the ihp, ehp, efficiency and r. p. m. averages for each run, together with the actual time the engines are in operation and the total energy in hp-hours developed by each engine.

Table of Totals.—In this table are shown, in the same thesis, the grand total for the three runs.

Table of Summaries.—In this table the average total ihp is derived by dividing the total energy of all of the engines developed by the time the engines are in operation. The total for water evaporated includes the steam used by the auxiliary machinery, but not that used by the heating system, etc.

The Characteristic Curves.—These are shown in the same thesis, and include the actual ihp for each engine and the grand totals.

The Engine Log.—Readings were taken every fifteen minutes, the signals being given as follows:

Three signals—Two minutes before time, to take the r. p. m.

Two signals—One-half minute before time, to get ready.

evaporated includes the steam used by the auxiliary machinery.

One signal—On time to take cards and electrical readings.

The electrical machinery of this plant includes seven 200-kw Edison; six 250-kw Thomson-Houston, and three 800-kw General Electric generators; four 500 kw 25-cycle G. E. rotaries receiving current from Niagara Falls; a 272-cell, 3000 amp.-hour battery capable of being discharged in one hour; and a 3000-amp., 70-volt battery booster, compound wound and motor driven in such a manner as to compensate automatically for the drop due to the internal resistance of the battery causing it to take the station load fluctuations. The normal station bus-bar pressure is 550 volts.

Necessary electrical readings were made to secure the following facts relating to the operation of this power plant:

(1) The load factor of the station, *i. e.*, the ratio of the mean average load for twenty-four hours to the maximum average output, not including fluctuations.

(2) The per centage of variation above and below the average during times of maximum and minimum load on the station, making note at the same time of the probable number of cars in operation from the station.

(3) A daily output curve showing the charge and discharge of the batteries in comparison with the output of the station.

(4) The efficiency of the storage battery, that is, the per centage of energy delivered to the battery in twenty-four hours that is usefully returned.

(5) Regulating curve of the batteries, that is, the voltage during charge and discharge with various currents.

(6) The probable saving in coal consumption due to steadier load obtained by the use of the battery, and the extent to which the battery permits operation of the station with less capacity in generating units than if it were not used.

The output in current and bus-bar pressure of each generator and rotary, and the input of the battery booster were observed each quarter hour on signal at the same moment that the indicator cards were being taken. The battery current was under constant observation; the average current was charted every twenty seconds. The battery pressure was read every five minutes.

The following electric instruments and apparatus belonging to the Sibley College were used in making the above readings and for calibrating available instruments that belong to the power plant:

2 Weston voltmeters, range, 600 volts.
12 Weston millivoltmeters, range, .06 volts.
3 Weston mangain shunts, range, 2,000 amps.
5 " " " " 1,000 "
13 " " " " 500 "

A large number of cast copper connections which were machined to fit the shunt blocks and to connect them to the machinery terminals.

Three sets of No. 10 B. & S. G. 12-ft. connecting wires, and double throw switches for using one millivoltmeter on either of two machines, in three instances.

The voltmeters and millivoltmeters were calibrated in the department of electrical engineering in Sibley College by comparison with a set of Carhart-Clark standard cells. These compariparisons were made by means of a fine Nalder potentiometer and a steady pressure that is furnished over a range of 150 volts by an open circuit battery of 120 cells of the "Badt-Hermetic" type.

The resistances of the shunt blocks were determined by comparing them with a 1000 amp. .0001 ohm Board of Trade standard and a 500-amp. .001 ohm Reichsanstalt standard. The comparisons were made by passing currents from 250 to 1000 amps. through the shunts and reading the falls of potential produced, by means of the millimeters calibrated in the above manner. The current constant for any millivoltmeter combined with any shunt is then quickly determined. Since it is merely necessary to divide the volts per scale division on the millivoltmeter by the resistance of the shunt block and the result will be the constant of the instrument in amperes per division.

In this manner the electrical instruments were calibrated in terms of international volts and amperes with an absolute error not greater than one-fifth of 1 per cent.

The instruments from which the output of the rotaries, the input of the booster motor and the battery current were read belonged to the power plant. These were carefully calibrated by comparison with the Sibley College electrical instruments.

The battery ammeter was of the large Weston illuminated dial, plus and minus scale, pattern. Two observers devoted all their time while on duty to the observation of this instrument. One watched the pointer constantly, and at the end of each twenty second period called out the average value of the current during the third of a minute just past; his colleague charted this reading immediately and gave him the necessary time signals. This was very trying work. The young men were assigned to this duty

for but two hours at a time. The behavior of the battery was thus observed continuously for seventy-two hours.

The results of this test were computed and charted by the following men in the production of their theses: R. H. Dearborn, A. B.; J. M. Gilchrist, C. R. Scott, J. E. Hess, W. L. Cook, C. E.; G. B. Woodhull.

The books that contain the calibration records, and the figures and battery charts constituting the original readings are on file in the department of electrical engineering.

The following tables give the more important results that have thus far been deduced:

ELECTRICAL SUMMARY

Day of 24 Hours	Engine Indicated Hp-hours	Generator Output Hp-hours	Battery Hp-Hours		Rotaries Output Hp-Hours	Total Output E. Hp-Hours Without Rotaries
			Charge	Discharge		
1	------	79,410	7,225	1,487	30.630	73,672
2	69,900	61,300	5,350	1,950	37,500	59,900
3	107,700	92,600	6,100	1 500	------	88,000
4	53,250	46,600	------	------	31,100	46,000

The battery efficiency is not to be determined by taking the ratio of the above discharge to charge hp-hours. An efficiency thus determined would be very unfair for the reason that the above values do not include charges and discharges that occurred within quarter hour periods. These figures do not include momentary charge and discharge energies that occur through the load—regulating duty that the battery performs. The charging values include all the losses incurred through such process and the energy stored for greater periods than one-quarter of an hour. The discharging values include only those discharges of energy that were retained by the battery for one-quarter of an hour or more. To find from these battery values the battery loss incurred in having it carry the momentary station fluctations, the discharge hp hours must be divided by the ordinary battery efficiency, say .75, and the result subtracted from the corresponding hp hours. The result will give the hp hours lost in the battery in taking care of the station fluctuations. Owing to the fact that a battery will carry over energy from one charge to another even when discharged to the same pressure each time it is necessary to determine this regulating cost as an average for the three days during which the battery was under observation.

Total charging hp hours.....18,675
Total discharging hp hours..... 4.937
Average battery regulating cost per day,

$$18{,}675 - \frac{(4937 \div .75)}{3} = 4035 \text{ hp hours.}$$

FUEL CONSUMPTION

Day	Output Elec Hp-Hours Generated. Does not Include Rotaries	Water From and at 212° in lbs. per Elec. Hp-Hour	Coal, Dry, in lbs. per Hp-Hour	Remarks
1	73,672	35.7	4.11	Battery and rotary used
2	57,900	34.1	4.23	Battery and rotary used
3	88,000	33 5	4.04	Battery only used
4	46,000	34.2	4.17	Battery not used

The table above shows only a portion of the saving which is produced by the storage battery. During the entire twenty-four hours, current at the rate of 2000 hp is supplied continuously from Niagara Falls and charged to the railroad company. This current would only in part be utilized during the time when the engines were slightly loaded, as for instance during the period after midnight. The results of test show that the storage battery receives from the Falls power, when the engines are not in use, current sufficient in the aggregate for 3000 hp-hours.* During the operation of the plant the load factor on the engine plant is kept high by stopping any engine just as soon as any evidence of a light load on the station is shown. There are a great number of cars in operation on the various railroad lines, so that the load fluctuations are light, making this practice feasible. This practice insures that under normal working conditions the engines are not operated for any appreciable time with a light load; on the contrary, each is worked within such load limits as to produce little variation in economy. For these reasons the above test cannot be considered as showing what saving might be effected in any station in which the load on the engines has an extreme and wide variation. By comparing the results of the tests on the third and fourth days, which were exactly similar except for the fact that the battery was in use on the third day in connection with the engines, and the engine plant only on the fourth day, it will be noticed that the saving due to use of battery is about 4 per cent. The effect of the battery in preventing fluctuations of the load of small amount and short duration, was quite marked, and aside from the slight saving due to its use, there is doubtless a further saving because of steady load and less repairs to engines.

There are many items of interest in the results obtained from this test that can not be given at this date owing to the large amount of labor involved in their deduction.

* During the period of the test there was a heavy snow fall, making a large night load, which reduced the usual saving due to this cause to 1600-h. hours.

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED JULY 10, 1900.

653,218. Motor Controller; D. H. Darrin, Cranford, N. J. App. filed Sept. 2, 1899. With this controller the motor can be stopped at any point short of full speed by breaking the circuit through the manipulation of an extra circuit closer on the handle of the controller and without the necessity of moving the controller handle back to the starting position.

653,316. Trolley; W. H. Russell, Watertown, N. Y. App. filed Nov. 23, 1899. The flanges and tread of the wheel are of hard metal, while the hub, which is not subjected to wear, is of softer metal, the flanges and tread being removable from the limb.

653,402. Safety Trolley; J. W. Richmond, Fishkill-on-the-Hudson, N. Y. App. filed March 28, 1900. Details.

653,441. Grip Mechanism for Cable Railways; J. Craig, Jr., New York, N. Y. App. filed Aug. 4, 1898. This invention relates to that class of grips which are provided with ejectors by which the cable is thrown out of the jaws of the grip, the improvements consisting in certain details of construction.

653,443. Car Brake; R. W. Ennis, Buffalo, New York. App. filed Dec. 27, 1899. Power is applied to the brake shoe from the axle, a clutch being thrown in by the hand lever.

653,522. Car Truck Bearing; F. R. Northan, Chicago, Ill. App. filed Feb. 12, 1900. The object is to provide means for raising the car body to allow for sagging. This is done by making the bearing plate on the truck concave, and that on the body convex, and inserting a concave-convex plate between the two bearings.

653,532. Fastening for Rail Joints; F. W. Schinnel, Portland, Ore. App. filed Dec. 12, 1899. To dispense with nuts in the fastening of fish-plates, the bolts are passed through button-hole slots in the fish-plates.

653,549. Electric Trolley; T. Derrick, Lansingburg, N. Y. App. filed Jan. 27, 1900. Details of a ball bearing.

653,565. Rail Joint; B. O. Ward, of Oak Park, Ill. App. filed Jan. 26, 1900. One of the fish-plates is U-shaped in cross section, and a flange projecting upward from the chair plate rests against it, and is held thereto by bolts, which clamp the parts sufficiently to afford a spring pressure on the nuts.

653,604. Metallic Cross Tie; J. Q. Adams, Manchester, Vt. App. filed March 17, 1900. The tie, at the point where the rail rests upon it, is provided with a socket in which is placed a spring on which the rail rests.

653,634. Apparatus for Automatically Applying Car Brakes; S. F. Woodruff, Clippergap, Cal. App. filed Nov. 11, 1899. A portion of the train pipe is placed within the range of a shearing knife, which cuts it off and allows the air to escape in case the truck runs off the track. The escape of air effects the application of brakes.

11,840. (Reissue.) Contact System for Electric Railways; W. Grunow, Jr., Bridgeport, Conn. App. filed May 29, 1900. This invention covers improvements on prior patent, No. 586,845, and relates particularly to the mounting of an electromagnet which moves bodily when energized to complete the circuit to the working conductor, the current passing through the core of the magnet.

11,841. (Reissue.) Traveling Cable Grip; E. I. Parsons, San Francisco, Cal. App. filed Jan. 30, 1900. The movable jaw of the grip is a nut in which a screw works, the threads of the screw being made rapid, so that a short movement of the crank will set up the jaw.

PERSONAL MENTION

MR. N. E. MORTON, superintendent of the Lawrence division of the Lowell, Lawrence & Haverhill Street Railway Company, of Lowell, Mass., has resigned that office.

MR. D. L. LAVENBERG, formerly chief train dispatcher for the Wheeling & Lake Erie Railroad, has been appointed chief

train dispatcher for the Toledo, Fremont & Norwalk Electric Railway.

MR. J. B. HOGARTH has been appointed auditor of the Denver City Tramway Company. Mr. Hogarth was formerly chief clerk and auditor of the Florence & Cripple Creek Railroad. Mr. Hogarth's fellow-employees on the Florence & Cripple Creek Railroad presented him with a handsome umbrella on his departure.

NEWS NOTES

[News notes for this department are solicited.]

LOS ANGELES, CAL.—The rate war between the Los Angeles Pacific Electric Railway, the Santa Fe and the Southern Pacific to Santa Monica is on in earnest. There is every indication of a big cut in rates in the near future. The electric railway has thus far met the cuts made by the steam roads, and seems to enjoy a large part of the traffic.

BRIDGEPORT, CONN.—Two companies were organized at the offices of Marsh, Merwin & Lemmon, July 12, which, for the near future, at any rate, will be intimately associated with one another. The companies are the Moodus & East Hampton Railway Company and the Mutual Construction Company. The former company was organized for the purpose of building an electric railway to connect East Hampton and Moodus. It will be incorporated under the laws of Connecticut, and the following officers have been elected: F. C. Fowler, of Moodus, president; Clifton J. Harvey, treasurer, and E. C. Crocker, of Bridgeport, secretary; board of directors, F. C. Fowler, Charles E. Brownell, Mr. Chaffee, Clifton J. Harvey, E. C. Crocker, William Markham, E. S. Boyd, A. D. Warner and William A. Redden. The company is capitalized at $150,000, all of which has been subscribed. Of this $15,000 has been paid in. Plans for the work of constructing the road have already been made, and work upon it will be started as soon as the act of incorporation has been passed. All work will be under the supervision of Mr. Crocker, the electrical engineer. As the plans now stand, four gangs, combining about 400 men, will be put to work on four different sections of the road. The Mutual Construction Company will engage in all kinds of construction work. It was capitalized at $10,000, and $2000 has already been paid in. Officers were elected as follows: E. S. Boyd, of Woodbury, president; E. C. Crocker, secretary and treasurer; board of directors, E. S. Boyd, E. C. Crocker, William A. Redden, Clifton J. Harvey and A. D. Warner. It is more than probable that the contract for building the Moodus & East Hampton Railway will be given to the Mutual Construction Company, although no contract has as yet been made.

WILMINGTON, DEL.—At a meeting of the stockholders of the Wilmington & New Castle Electric Railway Company, held July 10, the following directors were elected: Peter J. Ford and Peter L. Cooper, Jr., of Wilmington; K. J. Koch, of Pottstown, Pa.; F. H. Treat, of Wayne, Pa.; R. Steen Martin and C. P. King, of Philadelphia, and Harry A. Richardson, of Dover. Officers were elected as follows: F. H. Treat, president; R. S. Martin, secretary; C. P. Kink, treasurer.

JOLIET, ILL.—The City Council has passed, over Mayor Mount's veto, the ordinance granting the Joliet Railway Company a twenty-year franchise for a double track on its new Chicago-Joliet lines, and a franchise for a line across the new bridge over the drainage canal at Cass Street. Mayor Mount attempted to get clauses inserted providing for a larger compensation, for restriction of the rate of fare, and for other restrictions, but his objections were voted down by the Council.

MACON, ILL.—The Hervey City & Southern Electric Railway Company has been incorporated, with a capital stock of $15,000, to construct an electric railway from Hervey City to Shelbyville. The incorporators and first board of directors of the company are: J. S. Butrum, of Decatur; Robert B. Hennigh, of Prairie Home; Robert H. Woodward, Harold R. Woodcock and John M. Turner, of Macon.

GALESBURG, ILL.—At the annual meeting of the stockholders of the Galesburg Electric Motor & Power Company, held July 9, the old board of directors was re-elected for another year, and John G. Vivion was chosen to succeed the late Wilkins Seacord. The other directors are: B. F. Arnold, Robert Chappell, W. W. Babcock, J. K. Mitchell, G. L. Price, Fred Seacord and Loren Stevens. The usual reports were received and submitted to committee for examination and the board of directors did not meet at the close of the session of stockholders. The present officers will hold over until the meeting of Aug. 7.

INDIANAPOLIS, IND.—The County Board of Review defends adverse criticism of its action in having reduced the assessment for taxation against the Indianapolis Street Railway Company $500,000, asserting that at the time the State Board raised the valuation to $3,000,000 last year, there was prejudice against the company. The Board says that it is certainly unfair to assess the regular dividend-paying companies like the Belt Railroad and Stock Yards companies and the gas companies at $2,500,000 and $1,000,000 respectively, and placed the Indianapolis Street Railway Company at $3,000,000, when no dividends were being paid and the stock selling for 22 cents. The company's revenues, it was said, were also reduced $30,000 a year by its bonus to the city, the people were getting a 4-cent fare and the system was being improved at large expense.

FT. WAYNE, IND.—The Knickerbocker Trust Company, of New York City, has entered suit in the United States District Court against the Lake Side Street Railway Company, asking that a receiver be appointed for the company and seeking to foreclose a mortgage on the property for $60,000, with accumulated interest. The suit is also against the Ft. Wayne Traction Company. The petition asks that the entire plant be sold to satisfy the claim, and that if the proceeds of the sale be not sufficient to satisfy the mortgage, the bondholders be made personally liable. It also asks for an injunction prohibiting the directors from transferring any of the property of the road without the consent of the court.

ROCKVILLE, MD.—At a special meeting of the Mayor and Council, held July 7, the ordinance granting the Washington & Rockville Electric Railway Company right of way along the main street of the town from the present terminus of the road at the fair grounds to the court house was rejected, and a committee, consisting of Mayor Spencer C. Jones and Councilman Hattersley W. Talbott, was appointed to prepare an ordinance which will meet with the approval of the Council, as well as the wishes of the people of the town. The law requires that the action of the Council shall be ratified by a majority vote.

BANGOR, MAINE.—The employees of the street railway companies operating in this city received the following notice from the Bangor Young Women's Christian Temperance Union July 3: To the conductors and motormen of the electric cars, the members of Elizabeth Yates, Y. W. C. T. U., wish to express their sympathy for the long and fatiguing labors of the men who run the cars; and as a token of respect felt for the constant care and kindness shown to those who ride, and for the fortitude which faces all the weather that comes seven days in the week; and as an invitation to the total abstinence principles which in railroad men are so important to the safety of the public, they hereby extend an invitation to each superintendent, conductor and motorman to call at the waiting room, 17 Main Street, on Wednesday, July 4, after 9 o'clock a. m., and receive a bouquet. The Ys.

MILFORD, MASS.—As the result of an agreement which was reached July 12, the Milford, Attleboro & Woonsocket, the Milford, Holliston & Framingham, the Marlboro, Westboro & Grafton street railway companies have virtually combined their interests. Directors I. A. Kensey, G. A. Butman, I. W. Downs and James Harwood, of the Milford, Holliston & Framingham Street Railway, have formally petitioned to the Selectmen of Milford for permission to extend their line to the Hopkinton town line.

WEBSTER, MASS.—Car No. 14 of the Worcester & Webster Street Railway Company collided with car No. 13, of the Webster & Dudley Street Railway Company shortly before 8 o'clock on July 4, killing two persons and injuring forty. The accident occurred at a point opposite the estate of the late W. S. Slater at East Webster.

WORCESTER, MASS.—A car of the Worcester Consolidated Street Railway Company jumped the track on July 9 and crashed into a farm wagon, spilling the market vegetables, which the latter contained, over the roadway. Three passengers were injured by the accident.

IONIA, MICH.—There are prospects of a bitter franchise fight here. Frank H. Talbot, of Detroit, has signified his intention to build an electric railway from Ionia to Saranac, Lowell, Ada and Grand Rapids, and now T. B. Preston, representing Ionia and Detroit capital, has announced that he will apply to the Council for a line to take in the Crystal Lake resort, with the probable extension later to Portland, Grand Ledge and Lansing. As the latter proposal is largely backed by local capitalists there are at this early date indications of partiality for the local enterprise.

DETROIT, MICH.—A car of the Sherman Street line here jumped the track July 4. Six persons were injured by the accident.

ST. LOUIS, MO.—The St. Louis County Court has passed an order granting the St. Louis & Fenton Railway Company an extension of time in which to begin work on its proposed electric line from the city limits at the Morris Road to Fenton.

NEVADA, Mo.—At a recent meeting of the Missouri Water, Light & Traction Company, Thomas Donahoe and Miss Ida Moran were elected directors to fill the vacancies caused by the resignation of S. A. Wight and C. M. Shartel. H. M. Duck resigned as treasurer of the company and was elected vice-president, and Miss Ida Moran was chosen treasurer of the company.

KANSAS CITY, MO.—Two persons were injured in a rear-end collision of electric cars here, at Independence Avenue and Campbell Street, on July 4.

ST. LOUIS, MO.—The St. Louis Transit Company has just put in operation two loop systems, which are intended to relieve the congestion on the Transit lines in the West End. The new loops will greatly facilitate the handling of heavy crowds which patronize the summer gardens and other resorts in this district.

CAMDEN, N. J.—The street committee of the Camden City Council has adopted the Bonham fender, with the Sterling wheel guard, for use on all trolley cars in Camden. This fender had been selected by the Camden & Suburban Railway Company.

WESTFIELD, N. J.—On July 11 the Westfield & Elizabeth Street Railway Company reduced the fare from this place to Rahway from 10 to 5 cents, and passengers are now being carried from the Westfield to the Rahway depots at that price. The company is now preparing a ticket which will be good for a continuous ride from Elizabeth to Boynton Beach for 20 cents, providing the passenger asks for the ticket when the fare is paid. The regular fare to Boynton Beach at the present time is 25 cents. This new ticket will be put in use at an early date.

BROOKLYN, N. Y.—The gripmen and conductors on the Brooklyn Bridge have been organized into an open union, under the auspices of the American Federation of Labor. A charter was received from the A. F. of L. a few days ago, and the organization will be known as the New York and Brooklyn Bridge Employees' Protective Association. The members deny that they have organized for the purpose of making new demands.

LIBERTY, N. Y.—The Liberty & Jeffersonville Electric Railroad Company has contracted with the Houk Falls Power Company, of Napanoch, to furnish power for operating its new road.

STREET RAILWAY JOURNAL

WEEKLY NEWS ISSUE

SATURDAY, JULY 28, 1900.

PUBLISHED WEEKLY BY

THE STREET RAILWAY PUBLISHING COMPANY

MAIN OFFICE:

NEW YORK, BEARD BUILDING, 120 LIBERTY STREET.

BRANCH OFFICES:

CHICAGO.....Monadnock Block
PHILADELPHIA.....929 Chestnut Street
LONDON.....Hastings House, Norfolk Street, Strand

Correspondents in other Principal Cities of the World.

Long Distance Telephone, "New York, 4044 Cortlandt."
Cable Address, "Stryjourn, New York."

Copyright, 1900, The Street Railway Publishing Co.

TERMS OF SUBSCRIPTION.

In the United States and Canada.....$4.00 per annum
In all Foreign Countries, per annum.....$6.00 / 25/ / 31fr.

Subscriptions payable always in advance, by check (preferred), money order or postal note, to order of C. E. WHITTLESEY, Treasurer.

EDITORIAL NOTICE.

The news issues of the Street Railway Journal are devoted primarily to the publication of street railway news and current happenings related to street railway interests. All information regarding changes of officers, new equipments, extensions, financial changes and new enterprises will be greatly appreciated for use in its columns.

All matter intended for publication must be received at our office not later than Wednesday morning of each week in order to secure insertion in the current issue.

Address all communications to

THE STREET RAILWAY PUBLISHING CO
120 Liberty Street, New York.

Separate Car Acts in Montgomery and Columbus

The City Council of Montgomery, Ala., has passed an ordinance requiring the Montgomery Street Railway Company to provide separate cars for the transportation of whites and negroes. The company is given thirty days in which to comply with the conditions of the ordinance. The ordinance passed by the Council of Columbus, Ga., differs from that passed by the Montgomery Council in that it provides for the separation of the whites and blacks in the same car, and does not require the operation of special "black" cars. By the terms of the latter ordinance the motormen and conductors are compelled to assign seats to passengers, the front half of the car being reserved for the whites and the rear half for the negroes. If a passenger refuses to take a seat assigned him he is liable to a fine, or if the motorman or conductor fails to assign a seat he is liable to a fine.

Rapid Transit Commission for Cleveland

At a recent meeting of the City Council a resolution was introduced calling for the appointment of a rapid transit commission. The object of the commission, as explained in the resolution, is to arrange, if possible, private rights of way for the suburban electric lines from the city limits to the Public Square, in order to allow them to make the same time in the city as outside, bringing the suburbanites into the heart of the city at steam railway train speed. The resolution states that there are many streets in Cleveland traversed by suburban cars which travel at a rate of speed exceeding that fixed by the city ordinance covering this point. This, the resolution states, is a menace to the safety of the public and should not be allowed. It is conceded, on the other hand, that the suburbanites and also the citizens living in the outskirts of the city have the right to be brought down town and taken back to their homes with as much dispatch as possible. The resolution further states that the increased population in the outskirts demands speedier service. The commission, as set forth in the resolution, is to consist of five members, whose duty it shall be to arrange a special service, if possible, and one that will prevent accident.

Verdict in Favor of the Brooklyn Rapid Transit

The Appellate Division of the Supreme Court in Brooklyn has decided, in a test case submitted, that the Brooklyn Rapid Transit Company has a legal right to charge a 10-cent fare to Coney Island. The case was that of Arthur Barnett, who got a judgment for $65 against the company for being ejected from a car after refusing to pay an extra 5 cents. Justice Hirschberg writes the decision, and his associates concur except Presiding Justice Goodrich, who was absent. The decision, which is quite voluminous, sustains these points:

First—That the Brooklyn Heights Company legally leased the Sea Beach Railroad.

Second—That this lease carries with it the right to charge an extra 5-cent fare.

Third—That the Sea Beach road received its charter before the One-Fare law was passed.

Fourth—That the One-Fare law did not refer to roads with a steam railroad franchise.

In closing Justice Hirschberg says:

"From the statutes and decisions cited it would seem evident that the defendant is entitled to make the charge complained of unless prohibited by the fact that it operates a street railway in connection with the Sea Beach road. As Section 101 of the Railway law does not apply to the latter road the 5-cent fare provision can have no force in this connection. There is, consequently, no express legislative prohibition, and surely there is no occasion for a forced construction of the law for the sake of creating one. No reason can be suggested for such a construction of the Railway law as would permit the defendant to convey its passengers from the Brooklyn Bridge to Coney Island at a charge of two fares, provided the passengers were subjected to the annoyance and inconvenience of alighting at the junction of the two roads and there purchasing a ticket and boarding another car, but which would deprive it of the right to charge the second fare merely because it had voluntarily constructed a temporary union of the two roads at that point in order to promote the comfort of passengers by affording a continuous and uninterrupted transit."

The application of former Senator McNulty to annul the franchise of the company for charging the extra fare is still pending before the Attorney-General. He refused to become a party to the test case before the Appellate Division.

New York Railroad Commissioners Report on Brake Tests

On July 23 the State Board of Railroad Commissioners, of New York, issued a report on the official test which it made of automatic street-car brakes to supplant the hand brakes now in use. The tests were made nearly a year ago on Lenox Avenue, New York City, the Metropolitan Street Railway Company granting the Commission permission to make the test on its lines and with its cars. In its report the Board says:

"The Board has devoted much time to this test, and while nothing has been brought forth that will revolutionize the manner of stopping a car, the opportunity is afforded to present to the railway officers and to the public facts and figures showing what the best appliances known to-day can do in the matter of stopping a car quickly. While these results are very satisfactory, there is still room for much improvement, and the Board feels that its action in holding a public test will result in still further improvements in brakes or in new inventions which will reduce the distance within which a car can now be stopped, and it has the satisfaction of knowing that it has done all in its power to bring about the adoption of better brakes than those now used by the majority of roads in this State, and thus reduce the number of accidents.

"It is not the intention of the Board to recommend any particular brake for any class of service, leaving the selection to the judgment of the railway officers themselves. The Board will, of course, exercise fully its powers under the law to require of the companies the use of sufficient and safe equipment for the public service. After a careful consideration of the whole subject of brakes for electric cars, the Board has determined that, except in special cases where the liability of accident is very remote, the ordinary single chain and spindle hand brakes, now generally used, should be replaced by brakes made by one of the following manufacturers, or any other which, in the judgment of the Board, is hereafter shown to be equally efficient:

"Air brakes: The G. P. Magann Air Brake Company, the Standard Air Brake Company, the Christensen Engineering Company, J. E. Reyburn. Electric brakes: The Electric Selector & Signal Company, the General Electric Company. Friction brakes: The Peckham Motor Truck & Wheel Company, the J. G. Brill Company. Hand-power brakes: The Sterling Supply & Manufacturing Company, M. H. Vogel, the Sauvage Street Car Brake Company."

Department of Blanks and Forms

The secretary of the Street Railway Accountants' Association of America has issued the following circular:

(CIRCULAR NO. 14.)

New Orleans, La., July 16, 1900.

To the Members:

The value of the Department of Blanks and Forms can be greatly enhanced, from year to year, by the addition of the new forms issued by your company, and the refiling of those blanks reissued. Therefore, it is hoped and anticipated that you will cooperate with the secretary in the effort to make the department a continual advantage of membership in the association, and keep it sensitive to the changes of your blanks and forms.

As the rubber stamp comes naturally within the meaning and intention of this collection of forms, a separate book is to be devoted to rubber-stamp impressions, and there is no doubt that it will not be the least interesting of the whole. It is preferred that the impression be made upon white paper 4 ins. wide by 6 ins. long; each impression on a separate slip of paper. Print on one side only.

Electric lighting in many instances is managed in the offices of street railway companies. Electric lighting blanks are, therefore, of interest to those companies, and if your company has this adjunct, please include the blanks in your package.

Experience has shown the need of the following suggestions, and they are given with the hope that they will be heeded in forwarding your package:

1. Do not fold the blanks; rolling is preferred.

2. Write in ink the name of your company upon all blanks where same does not appear.

3. The term "blanks and forms" covers everything printed in use by your company, books, circulars, rubber stamps, tickets, transfers, statements and reports.

4. Please send at least two copies of all forms, except of rubber stamp impressions.

5. Address your package to W. B. Brockway, Secretary, Post-office Box 630, New Orleans, La., and advise by letter of its forwarding.

It is appreciated that you will be put to some trouble to comply with this request, but it is believed that you will do it willingly, for you understand the importance of the collection.

The companies that complied with the request made Circular No. 6, Nov. 15, 1898, will consider this request to apply to their issue and reissue since that date. But the companies which have joined since then will please include their entire issue at the present time. Yours truly W. B. Brockway, Secretary.

C. N. Duffy, President.

Some General Conditions Governing Power Station Design *

BY PHILIP DAWSON

At the present moment when electric traction is making such rapid strides, the question of the source of supply of power is a very important one. In this paper it is proposed briefly to consider this question from the economical point of view. This is the most important one, and the engineer's knowledge and experience should be used to design and construct the source of supply of electrical energy in such a manner as to furnish the board of trade unit at the switchboard at the lowest possible cost, interest on capital, depreciation and sinking fund included. It may be argued that the cost of the unit at the switchboard being low, it does not necessarily follow that the cost of the power, say, per car or per train mile will also be low, as it is possible that in order to secure cheap current the power station may be so located as to cause great expense in feeders, sub-stations and loss in the transmission. In the numerous cases, both in Great Britain, on the Continent and in America, which have come under my notice, I have never found this to be the case. This applies to power supply stations intended for traction and power primarily and lighting secondarily. It may be mentioned at once that the demand for current for both traction and power transmission purposes is increasing so rapidly that lighting will shortly in any case be only a secondary consideration.

The combination of a lighting and traction station is, therefore, not to be recommended, and good results cannot be expected. The case is, however, entirely different where traction and lighting are combined, and the best results are then obtainable; that is to say, where the station has been designed by experienced traction engineers for traction and lighting.

It may be of interest to consider what are the differences between a station designed for lighting and one designed for traction and power transmission.

The average number of hours per annum during which a lighting station will be running full load, will probably never be equivalent to more than three months' continuous running per annum; that is to say, taking the total kilowatt-hours generated in one year, and seeing how long the plant under consideration would have to run its full capacity continuously to generate this amount, this time would probably never exceed three months. Taking a representative traction station, the time of continuous running would probably be at least nine and in some cases ten and even eleven months.

A lighting plant must in three months earn enough money to pay working expenses and to pay interest and allow for depreciation and sinking fund for a whole year, whereas a traction plant has from nine to eleven months to do the same thing.

A lighting plant is, on an average, practically at a standstill eighteen hours a day, while a traction plant is running eighteen to twenty hours a day. Economical boilers, engines and electrical generating and transmission devices are, therefore, far more important in a traction than a lighting plant, because it is well known that running at very light loads and keeping the fires banked and the boilers, steam pipes, engines, etc., hot, uses very nearly as much fuel as running them at full load.

Furthermore, whereas in a lighting plant there is ample time to overhaul the plant and execute necessary repairs, the men during the day have little or nothing to do and can well do this work. In a traction plant there is little or no time to do this. The conditions are quite, if not more, arduous than on a ship.

* Paper read at the meeting of the Tramways and Light Railways Association, London, June 27, 1900.

There at least every few days or few weeks the whole plant is entirely shut down for several days and can be taken to pieces and overhauled.

Unexpected and rapid overloads must be able to be supported by the traction plant, which is not generally the case in lighting.

In a traction station it will be seen that a far greater figure is cut by the cost of generation pure and simple than in a lighting station, and that the question of interest on capital expenditure and sinking fund is relatively smaller in the former than in the latter.

The following figures, which are the result of actual experience, may be of interest, and show the influence of continuous running on the cost of production:

COST IN PENCE PER BOARD OF TRADE UNIT (KW-HOUR)

	Lighting. Pence.	Traction. Pence.
Fuel	0.3 to 2.2	0.09 to 0.5
Oil waste and stores	0.05 to 0.38	0.005 to 0.2
Wages and salaries	0.28 to 1.60	0.03 to 0.4
Maintenance	0.054 to 0.6	0.0025 to 0.06
Total	0.684 to 4.78	0.1275 to 1.16

The difference which exists between a plant working practically continuously and only intermittently is at once seen in the average amount of coal consumed per unit generated. The type of engine used must, however, also be taken into consideration.

Thus, taking the published results of British electric-light plants, we find that the cost of coal per unit generated varies approximately between 0.3d. and 2.2d. Comparing this to traction plants, we find the cost of coal varying between 0.09d. and 0.50d. per unit generated. Again, considering the item of wages and salaries in a lighting station, we have 0.3d. to 1.6d.; in the case of traction, this is 0.03d. to 0.40d. per unit. Comparing the total cost of production of one Board of Trade unit generated in a lighting station and in a traction station, interest and sinking fund excluded, in the former the unit varies from 1.00d. to 4.00d, as compared to 0.25d. to 1.00d. for traction purposes. The cost of power when generated for traction and power purposes is one-quarter of that when generated for lighting only.

The amount to be added for interest and sinking fund, of course, depends on the length of the concession, on the terms of final purchase and on the life of the machinery employed. The cost of producing power varies with the amount to be produced, decreasing as the amount increases. This shows the advisability of concentrating as much power as possible in one station, and reducing the number of units.

In considering the various items which go to make a complete power or traction installation, including the system of feeders, distributors, track and overhead line, the cost of the power station is but a comparatively small item. The saving which can be effected by a properly designed station is very great, and a little extra capital expenditure is in many cases well justified.

The total cost of running an electric tramway or railway varies between 2.50d. and 8.00d. per car mile, according to circumstances; the electrical energy at the power station required varying from 0.49 units to 1.4 units per car mile, according to the profile of the line and the weight and speed of the cars.

The cost of power varies between 10 and 30 per cent. of the total working expenses, all charges included, and if it can be reduced by ¾d. to 1d. per unit or we may say per car mile, as one unit at the switchboard is a fair estimate of the average power requisite at the switchboard per car-mile run, it is well worth doing.

In the early days, before polyphase high-tension currents were known, the situation of the central station was practically imposed, very little latitude being possible, owing to the maximum distance of economical transmission being limited. Electricity works being most required in crowded centers, it was not only difficult to obtain a site at all, but the cost of the ground was very great. Hence the necessity of crowding the greatest amount of power into the smallest possible space. The plants being mostly used for lighting, and only running a few hours each day, highly economical engines and boilers and labor-saving appliances were of but little advantage. At present, circumstances have altered; electricity can economically be transmitted to any distance, and is utilized—and will be more and more so every day—firstly for power purposes, and secondly for lighting purposes.

The initial cost of a plant may be roughly divided into four parts: Land and buildings; plant, including all machinery in station; mains, feeders and distributors; miscellaneous, which includes such things as meters, instruments, cost of provisional order, and such like.

According to Emile Garcke's figures in the Manual of Electrical Undertakings, the average cost of existing British plants expressed in percentage of total capital expenditure is approximately as follows:

Land and buildings	19 to 23 per cent
Machinery and plant	35 to 37 per cent
Various remaining items	4 to 14 per cent

As regards the first item the above average includes several old lighting stations, and there is little doubt that if a new plant was installed the cost of land could be materially reduced.

The question of system of generation, whether in several large stations generating continuous current or in one large station generating either continuous or polyphase currents, is of great moment.

As already stated, in a traction station much greater capital expenditure is justified, and coal-handling appliances can be installed which enable one or two men to look after the largest boiler-room. Automatic lubricating system and ash conveyors, etc., enable one or two men to be sufficient in the largest engine-room. It will be evident that the item wages and salaries will be far greater in several than in one station. Also, the waste of coal, etc., will be far greater. From a careful study it is nearly certain that for anything above 5000-kw capacity, one polyphase station operating rotary converter sub-stations is the best. Large units are also always advisable. It interests me to see that the sizes I recommended several years ago are generally being adopted. For reference, it may, perhaps, be advisable to append this table:

SIZES OF ENGINES RECOMMENDED FOR USE IN POWER STATIONS

Maximum Power Required. ihp.	Number of Egines.	Power of each Engine. ihp.
200	2	200
400	3	200
600	3	300
1,000	3	500
1,500	4	500
2,000	4	750
5,000	6	1,000
10,000	6	2,000
20,000	6	4,000
40,000	9	5,000
60,000	11	6,000
90,000	10	10,000

All engine builders who have had experience in tramway work now make an entirely different kind of engine for traction from that which they supply for lighting stations. The conditions under which a tramway engine works are, if anything, more onerous than those of a rolling-mill engine. A slight variation, either in number of revolutions per minute, or in angular velocity per revolution, is of the greatest importance in a traction station, whereas it is of small importance in a rolling-mill.

A uniform speed is especially important where compound-wound dynamos are run in parallel direct on to the line. If the momentary difference in speed between two engines exceeds very narrow limits, the voltages of the machines differ, and cause very heavy currents in the equalizing bars and largely increased core losses, hence great waste. If the difference becomes too great, one of the generators may even be reversed. Where polyphase machines run in parallel, constant speed is of even greater importance to keep the machine in step. In cases where shunt-wound generators with heavy batteries of accumulators run in parallel on the line, the question of engine regulation is not so important.

A traction station where compound-wound dynamos are used should be so arranged that, if the normal load be suddenly thrown on or off an engine, the speed shall not vary more than 2 per cent either way. In some cases a maximum variation of 1½ and 1¼ per cent is all that is allowed. Where polyphase currents are used, constant speed is of even greater importance; and a guarantee should be required that under no circumstances shall the angular velocity during one revolution vary more than ½ per cent, and in some cases not more than half of 1 per cent. With heavy fly-wheels and governors properly designed for tramway work, it is quite practicable to fulfil the above conditions, or, expressed in a different way, in polyphase work the engine should not produce by variation of angular velocity a phase displacement of more than 5 degs. per half cycle.

From careful comparison of many existing systems it may be taken that the total cost of power, all fixed charges included, for one large station, as compared to that for two or more smaller stations, together equal in power to the larger one, is from 30 to 75 per cent lower.

Profits on Tramway Undertakings*

BY C. H. GADSBY, Wh. Sc., M.I.E.E.

All tramway directors and managers and the members of municipal tramways committees are alike interested in the great question of establishing in the working of their undertakings as great a difference between gross receipts and working expenses as it is possible to obtain, and I think, therefore, I need offer no apology for bringing this subject before those of you who have done me the honor of coming to hear this paper. My only regret is that in the short time at my disposal it is impossible to go more fully into a subject so worthy of investigation and requiring so close a study of detail.

It is an easy matter to increase the gross receipts upon almost any tramway by increasing the services or by affording additional inducements to the traveling public. It is also an easy matter to reduce the working expenses by curtailing the services, employing cheaper labor, and by many other means, some only temporary, others permanent. The problem is—how to increase the gross receipts without at the same time unduly increasing the working expenses. It is not sufficient merely to establish a low *ratio* between working expenses and gross receipts unless at the same time the actual *difference* between them is great.

Naturally the first direction in which one turns for improvement is toward increased gross receipts. Such an increase may be effected by raising or reducing the fares according to circumstances, by increasing the services, by putting on better cars, by better heating and lighting, by better attention, and by numerous other means, but of course the increase of service is the one to which receipts respond most readily.

The table A shows the increments in receipts upon a certain English steam tramway resulting almost entirely from the gradual and judicious adoption of more frequent service. In this instance it will be seen that the mileage has been doubled in seven years; the number of passengers has been more than doubled, as have also the gross receipts, while the working expenses have been increased only about 70 per cent, and the resulting net receipts have been multiplied by 3½. This has been effected without any change of system, without any unusual development in the district or any extension of the line. There has been a substitution of a portion of double line for single, to permit of the more frequent service, but the improvement may be justly attributed simply to the increased service.

TABLE A

Year	Mileage	Passengers	Gross Receipts	Receipts per Car Mile	Working Expenses	Expenses per Car Mile	Ratio Receipts to Expenses	Net Receipts
			£	Pence	£	Pence	Per Cent	£
1893	260,153	4,079,993	17,939	16.5	12,327	11.3	68	5,612
1894	267,150	4,250,343	19,187	17.2	12,793	13.7	62	6,394
1895	370,373	5,286,608	23,271	15.07	14,022	9.08	60	9,249
1896	418,840	6,425,348	28,033	13.6	14,984	8.5	53	13,049
1897	470,612	7,450,492	32,316	11.5	16,908	8.6	52	15,408
1898	497,813	8,144,917	35,393	17.06	19,861	9.5	56	15,532
1899	523,073	8,818,047	38,453	17.6	20,438	9.3	53	18,015

It is interesting to note that in this case the receipts per car mile have increased from 16.5d. to 17.6d., while working expenses have fallen from 11.3d. to 9.3d., and the ratio of working expenses from 68 per cent to 53 per cent.

It is not to be expected that the gross receipts can be increased in the same proportion as the mileage, and consequently, as a general rule, the receipts per car mile are reduced. It is a knowledge of this fact that has in many instances led tramway managers to adopt the policy of restricting the mileages in an endeavor to secure high receipts per car mile.

Receipts per car mile on British tramways vary from a lower limit in the region of 7d. to a higher one approximating to 2s. per car mile. Except under very exceptional circumstances any manager working a line so as to obtain gross receipts anywhere in the neighborhood of this higher limit does not fully appreciate the necessities of his district or of the earning capacity of his system.

I consider that for electric and cable lines any rise in receipts per car mile above 9d. should be at once checked by an increased mileage.

In the case of horse tramways, a similar process should be applied whenever the receipts rise above 12d., and in steam lines when above 14d. or 15d. Take an example: Suppose we have a system running 1,000,000 car miles per annum, with gross receipts at 12d. per car mile:

	Per Annum
Total gross receipts will then be	£50,000
Suppose working expenses are at 60 per cent, and therefore amount to	30,000
Net receipts will be	£20,000

Let now the mileage be increased 20 per cent, that is to 1,200,000 car miles per annum, and suppose the total gross receipts increase only at the less ratio of 15 per cent, and that in consequence of standing and managerial charges being spread over a greater mileage, the working expenses increase only 15 per cent also. We shall then have

	Per Annum
Total gross receipts	£57,500
Total working expenses	34,500
Net receipts	£23,000

In this case the gross receipts per car mile work out at 11½d., that is by increasing the mileage 20 per cent we have reduced the receipts per car mile from 12d. to 11½d., but have at the same time made an extra £3000 per annum clear profit.

It may be of interest to compare the working expenses of tramways with different motive powers.

Table B may be taken as a fair average of the working expenses of a horse tramway. It is derived by taking the average of the actual figures on five representative town tramways in this country for the year ending June 30, 1899. From this it will be observed that the average total working expenses amount to 9½d. per car mile, whilst horse power with renewals amounts to 4.19d. per car mile, and traffic expenses to 3.05d.

TABLE B

OPERATING EXPENSES ON ENGLISH HORSE TRAMWAYS

Line	Maintenance of Permanent Way	Horse Power	Renewals of Horses	Repairs of Cars	Traffic Expenses	All Other Expenses	Totals	Mileages
	£	£	£	£	£	£	£

Table C shows a similar statement of working expenses for steam tramways derived from the actual figures for representative tramways in this country. The striking figure in this table is that engine power costs 3½d. per car mile while repairs cost 1¾d. per car mile, together making 5¼d. The permanent way repairs are naturally heavier than for horse traction, the traffic expenses are lower, chiefly on account of the drivers' and conductors' wages being spread over a greater mileage in consequence of the higher speeds than with horse traction. The total costs amount 10¾d. per car mile, or 1d. per car mile higher than for horses, so that the advantage of steam over horse working is due to the higher receipts per car mile consequent upon the use of larger cars.

TABLE C

OPERATING EXPENSES ON ENGLISH STEAM TRAMWAYS

Line	Maintenance of Permanent Way	Locomotive Power	Repairs of Engines	Repairs of Cars	Traffic Expenses	All Other Expenses	Totals	Mileages

Table D gives the working expenses for eight electric lines in this country. All of the lines are operated on the overhead system, some by their municipal owners, and others by companies. It is in this case somewhat difficult to apportion the costs on account of the lack of uniformity in the allocation of charges.

*Paper read at the meeting of the Tramways and Light Railways Association, on June 29, 1900.

It will be noticed that the cost of motive power is much lower than with horses or steam, being only 1.36d. per car mile, or with engine and dynamo repairs 1.685d.

TABLE D

OPERATING EXPENSES OF ELECTRIC TRAMWAYS IN GREAT BRITAIN

LINE	Maintenance of Permanent Way	Motive Power	Repairs of General Plant	Repairs of Cars	Traffic Expenses	All Other Expenses	Totals	Mileages

Average pence per car-mile	.765	1.38	.305	.576	2.67	1.15	6.896	

It might be expected that the items for car repairs would be higher than with horse or steam traction on account of the repairs of motors and electrical equipments being now included, but as a fact the figure per car mile is about the same. I think this is accounted for by the fact that although the expenditure on each electric car is greater than on each steam or horse car, the charge per car mile is not greater on account of the greater daily mileage run by an electric car.

The item for traffic, which, of course, consists chiefly of drivers' and conductors' wages, is much the same for all three systems.

The total expenses of 6.8d. per car mile is somewhat higher than is generally expected with electric traction, this being due to the inclusion in the list of a number of small undertakings recently started, upon which it is reasonable to suppose improvement will be effected. When data are available from the many larger municipal undertakings just open or undergoing conversion, it is evident that an average total expense between 5d. and 6d. per car mile will be easily attained. In some cases in the table this has already been done, in the instance of line H the figures work out at 5.8d. per car mile, and on line G at 5.75d., while at Leeds, which is not included in the list, total working expenses are reported well under 5d. per car mile.

Table E gives the operating expenses per car mile well in detail for twenty-three American electric roads, and it is interesting to observe how closely this agrees with English working, notwithstanding the very different conditions.

Four years ago I had some difficulty in persuading a director of a certain large tramway undertaking in this country that there would be any reduction of working expenses by the adoption of electric traction, and at that time the figures I have given were not available. It is now scarcely necessary to point out that these figures show beyond doubt the great saving to be effected by the adoption of electric traction. This is the means that will be taken to reduce working expenses on every horse and steam tramway throughout the country during the next five or six years.

Having adopted electric traction there is still necessity for carefully watching operating expenses. In the first place the expenditure on track repairs may be anything from .05d. per car mile to 1.5d. It is necessary to keep sufficient men on the track to

keep pace with the wear, and the old proverb, "a stitch in time saves nine," is eminently applicable to track repairs, but it is at the same time an easy matter to waste money by having too many men on the work, who will always find or make something to do.

Then, again, the item for motive power may be anything from .5d. to 2.0d. per car mile. The first care in this respect should be as to the consumption of current upon the cars, which may on level roads with small cars and careful manipulation of the controller work out as low as .6 B. of T. units per car mile, or may, on heavy roads, with careless driving, amount to 1.3 or 1.4 B. of T. units per car mile.

Having reduced the consumption of current upon the cars, the next point is to secure its economical production. To effect this it is necessary to see that the fuel is of the most suitable character, having due regard to cost, and remembering that the lowest priced fuel is not always the cheapest, and that the furnaces are of the best type for dealing with it. It is also of the utmost importance for economical production that the engines and dynamos are of the proper power, so as to be fairly fully loaded without risk of injurious overloading in the heavy fluctuation of traffic.

In table F I give the sizes of a generating plant I have found suitable for operating lines with various numbers of cars under ordinary conditions.

TABLE F

Generating Plant for Various Numbers of Cars in Service on Electric Lines Under English Conditions

No. of cars	5	10	15	20	25	30	35	40	45	50
No. of sets of generating plant, including reserve	2	2	2	2	2	2	3	3	3	3
Power of each set in kilowatts	60	125	175	225	275	300	175	200	200	225

No. of cars	55	60	65	70	75	80	85	90	95	100
No. of sets of generat ng plant, including reserve	3	3	3	3	3	3	3	3	3	3
Power of each set in kilowatts	250	250	275	275	300	300	325	325	350	350

It is, of course, important that the plant shall be of the most economical description, but judgment must be used in selecting the plant, as to whether it shall have simple, compound or triple expansion engines, and as to whether it should be even condensing or non-condensing, as particularly in small plants in districts where fuel is cheap it may be found that where repairs, attendance, water, etc., are taken into account, it may be cheaper to adopt a non-condensing engine using 25 lbs. of steam per ihp per hour than a condensing engine using, say, 18 lbs. of steam per ihp per hour.

Then, again, there is the all-important matter of traffic expenses, which generally amount to about half the total cost of operating electric cars. Wages and hours for drivers and conductors are now fairly uniform throughout the Kingdom, and there is not much scope for cutting in this direction, and it is in the careful arrangement of shifts, and in the reduction of lost time at end of stops that reductions may be made. On many lines with short branches a very large proportion of the men's time is wasted while the cars are standing at termini. Cars should, as far as possible, be kept moving all the time, only sufficient time being allowed at the ends of the journeys to allow for turning the trolley pole and loading. In this way a good deal more mileage will be got out of both men and cars.

With the higher speeds in America it is common practice to get 100 to 120 miles per day out of a car, while in this country there are plenty of instances where electric cars are only doing 35 to 40 miles per day. Even with the limitations of speed to which we are here subjected, much better than this should be done.

These remarks have been based upon the operation of overhead trolley lines, but apply generally to electric conduit lines upon which, if substantially built, the working expenses will be much the same, the only difference being a small increase for repairs and maintenance of the conduit, conductors and collectors.

I have not included any statement as to the operation of cable lines, although these are worked at remarkably low rates, as low, in fact, as many electric lines, chiefly because there are only three systems of any magnitude in operation in this country, and there has been very little recent development in them.

I think we are justified in drawing from this small investigation the following conclusions:

1. That it is generally possible by increased services to increase the gross receipts.

2. That the operating expenses do not increase at the same rate as the mileage, and generally at a less rate than the receipts.

3. That services judiciously increased generally result in larger net profits.

4. That electric traction constitutes the readiest means of increasing the receipts, and at the same time of reducing working expenses.

5. That on tramways already equipped in this country there is scope for reduction of operating expenses and increase of profits.

I have to acknowledge my indebtedness to the Street Railway Journal, New York, to the compiler of "American Street Railway Investments," and to the officials of the various undertakings, whose figures have been cited, for their kind assistance in the preparation of this paper.

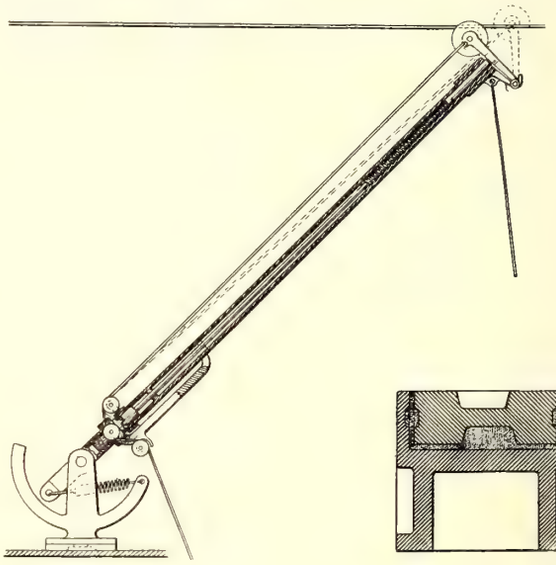
Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

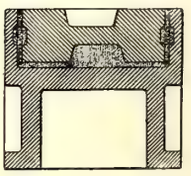
UNITED STATES PATENTS ISSUED JULY 17, 1900.

11,842. Reissue Fare Register; J. F. Ohmer and H. Tyler, Dayton, Ohio. App. filed May 11, 1897. The most important feature of this invention consists in actuating the total or trip registering device by means of mechanism arranged to be engaged or operated in common by each one of the individual fare indicator and register operating devices. The invention is an improvement upon the register described in patent No. 560,529.

653,649. Underground System of Electric Railway; C. A. Balph, Pittsburgh, Pa. App. filed Sept. 14, 1897. The main conductor is carried in a rubber or leather tube and connects with the sectional conductor by means of plugs carried by the latter and passing through the wall of the tube.



PATENT NO. 654,050



PATENT NO. 653,845

653,694. Car Fender; G. B. Quarrier, Los Angeles, Cal. App. filed April 5, 1900. Details of that type of fender in which the obstruction releases a latch to throw the fender into operative position.

653,769. Car Step; S. B. Fuller, Pawtucket, R. I. App. filed Sept. 13, 1897. Auxiliary steps are fitted with gearing so that the motorman or conductor can fold them up or open them at will from the platform, such steps being adapted for the higher cars.

653,780. Emergency Brake Setting Mechanism; W. H. Sauvage, Denver, Col. App. filed Sept. 12, 1899. By the movement of one lever the motorman can throw down the fender, apply the brakes and open the sand-box.

653,845. Railway Track Structure; H. O'Shea, Johnstown, Pa. App. filed Nov. 7, 1899. The plate which carries the track grooves at crossings, frogs, etc., are made double, i. e., with the grooves on both sides, so that the plate can be reversed when one side is worn out.

653,879. Motor Vehicles; L. J. Phelps, Melrose, Mass. App. filed May 19, 1900. The weight of the operator is utilized to keep a constant friction on the controller shaft and thereby hold it at any point to which it may be moved.

653,930. Fender for Tramway of Like Vehicles; J. Vonholt, Hamburg, Germany. App. filed Oct. 30, 1899. This fender is an elastic frame arranged at an angle and fitted with a number of vertical rollers so that the obstruction will be pushed to one side.

653,958. Convertible Open and Closed Car; F. Hoffer, Cohoes, N. Y. App. filed April 10, 1900. The side panels are made in sections hinged together so that they may be folded to occupy a small space beneath the roof of the car, when the car is operated as an open one.

653,975. Guard-Rail Fastener; D. F. Vaughan, Haddonfield, N. J. App. filed March 3, 1900. Details.

654,039. Spring Box for Frogs, Switches, Etc.; W. Wharton, Jr., Philadelphia, Pa. App. filed May 31, 1900. A special method of forming the box, for economy of manufacture.

654,050. Trolley Pole; C. A. Brown, Lorain, Ohio. App. filed Aug. 22, 1899. When the wheel leaves the wire it releases a catch which allows a spring to lower the pole.

654,105. Electric Railway Appliance; D. E. Shoop, Turtle Creek, Pa. App. filed Dec. 9, 1899. This trolley runs on top of the wire, and in order to pass crossing wires there are two trolley wheels on the same axis, which shift from one wire to another at the crossing.

PERSONAL MENTION

MRS. J. C. HUTCHINS, wife of Vice-President Hutchins, of the Detroit, Mich., Citizens' Street Railway Company, is dead.

MR. CHARLES L. HENRY, general manager of the Union Traction Company, of Anderson, Ind., had his leg broken below the knee a few days ago by a kick from a horse.

MR. A. A. McLEOD has resigned as president of the American Railways Company, of Philadelphia. William F. Harrity, vice-president and general manager of the company, has been tendered the place, and it is believed that he will accept it.

MR. HENRY C. PAGE has been appointed superintendent of the entire Lynn & Boston Railroad system. Mr. Page was formerly superintendent of the Salem division of the system, which position he has held for the past sixteen years. W. S. Wolcott has been appointed acting superintendent of the Salem division to succeed Mr. Page.

MR. ABRAM Q. GARRETSON, of Jersey City, who has just been appointed by Governor Voorhees to fill the vacancy caused by the death of Justice J. H. Lippincott, in the Supreme Court, has resigned from all the corporations of which he is a director. Among them are the North Jersey Street Railway Company, Newark Passenger Railway Company, and Newark Plank Railroad.

MR. J. D. NEWTON, who has been a division superintendent of the Washington Traction & Electric Company, of Washington, D. C., since the purchase by the company of the Anacostia road, has resigned. Mr. Newton has been engaged in street railway work in the District since 1888, and was the superintendent of the old Anacostia street car line for years. When the Anacostia road was purchased by the Washington Traction & Electric Company Mr. Newton was made division superintendent of the Congress Heights, the Anacostia and the Belt lines. He was transferred from the Anacostia division to the City & Suburban line in the same capacity a short time ago.

MR. E. C. FOSTER, vice-president and general manager of the Lynn & Boston Railroad Company, has just been appointed general manager of the Massachusetts Electric Companies, and will perform his dual duties for the Boston office of the latter company. Mr. Foster was born in Hancock, N. H., Oct. 23, 1852. He was educated in the public schools of that town and at Appletons Academy. At the early age of fifteen he decided to enter business, and secured a position as a clerk in a grocery store. He resigned this position after a year and went into the milk business for himself. After three years of this, he resigned to accept a position as a conductor for the Lynn & Boston Railroad. He was then nineteen years old. Two years later he resigned this position and spent two years in California. On returning to the Bay State he was again appointed a conductor on the Lynn & Boston, and in April, 1883, he was made division superintendent. In 1892 he was elected general manager of the company, which position he still fills in connection with his other offices.

MR. C. D. WYMAN has resigned as general manager of the New Orleans City Railroad Company to accept a position with Stone & Webster, of Boston, Mass. Mr. Wyman accepted the management of the New Orleans property in 1896, succeeding Mr. H. M. Littell, who was manager of the lines during their equipment with electricity. Mr. Wyman gained an enviable reputation while in New Orleans, greatly perfecting the street-car service in that city, and devoting considerable time to the development of pleasure traffic. He has been a prominent figure in social events at New Orleans, and was a member of several prominent clubs, among them the Progressive Union and Boston clubs. Mr. Wyman will be employed as an expert by Messrs. Stone & Webster, who now control valuable properties in all parts of the country. He will supervise the operation of the numerous lighting and railway plants controlled by Messrs. Stone & Webster, and this work will give him a larger field of operation without being too closely confined to the small details connected with the everyday operation of railway and lighting plants. The following resolutions were adopted by the directors of the company, at a meeting held July 11, to consider Mr. Wyman's resignation:

"Resolved, That the resignation of Mr. C. D. Wyman as general manager of this road (to take effect Aug. 1 next) be accepted with regret, and that the secretary be and is hereby instructed to convey to Mr. Wyman our approbation of his efficient and faithful services in behalf of this company during the period of his connection therewith, and to express our best wishes for his continued success in his new home."

On July 18 Mr. Wyman was tendered a banquet at the West End Hotel by the officials and employees of the company, who generally expressed regret at losing such an efficient employee. Among those present at the banquet were: C. D. Wyman, general manager; Captain John G. Wood, secretary-treasurer of the company; H. J. Dressel, superintendent of trains; John R. McGivney, assistant superintendent and purchasing agent; T. H. Tutwiler, engineer; E. B. McKinney, chief engineer of the power house; C. V. Cosby, assistant, H. A. Ferrandon, auditor; Joseph Bein, cashier; T. C. Rojo, master mechanic; Max Plohm, director of amusements; W. H. Renaud, Jr., claim agent; Judge Lawrence O'Donnell, attorney, and T. Tranchina, manager of the West End Hotel. Captain Wood, secretary-treasurer of the company, acted as toastmaster, and he called upon Judge Lawrence O'Donnell to offer a toast suitable to the occasion. Judge O'Donnell, in opening his remarks, called attention to the fact that the occasion was not one for rejoicing. On the contrary, the officials should regret the cause which brought about the little dinner party. He spoke of the career of Mr. Wyman since his arrival in New Orleans, his energy, fairness and executive ability, and he concluded his remarks with a most touching and appropriate tribute to the friendship for a man among men.

C. D. WYMAN

In reply, Mr. Wyman spoke of his fellow-workers as friends. Were a novelist writing the story of his arrival, he would say that upon a dark and rainy night a lonely passenger dragged his way down a dreary street, looking for a place he could call home. This passenger came into the city as a stranger, with only the acquaintance of two or three people and a very slight knowledge of the work before him. He found a people who met him more than half way and helped him to gain a success. The office associates gave him their confidence, and he had tried to merit it. The real success of the company was, first, due to the faithfulness and honest work of the officials, and he retained for himself a very small part of the credit, for if this force had not come to his assistance there would have been no success. Men might make riches or a great name, but the accumulation of true friends was a pleasure more precious and sincere than the gaining of fame. He compared his friendship for the office force to the meeting of ships at sea, which speak and separate, but to him these friendships are like the association of a single crew whose lives have been so closely interwoven that associations are never forgotten. The shallow things of the heart murmur, but the deep feelings lie dumb, and he found this doubly so when he tried to express his sincere thanks for the very elaborate illustration of good-fellowship which he was shortly to leave. One by one he spoke to the officials surrounding the table, and to each paid some pretty tribute and expressed some thanks for some almost forgotten kindness.

The Knoxville Traction Company, of Knoxville, Tenn., is now using a new and novel kind of transfer. A park coupon is attached to each transfer, and ten of these are good for a ride on the merry-go-round, and five are good for a ride on the gravity road at Chilhowee Park in the afternoon. The transfers are not good for use after these coupons have been detached, and when they were first put in use a number of passengers had to pay an extra fare because they had been detached.

NEWS NOTES

[News notes for this department are solicited.]

LOS ANGELES, CAL.—The Los Angeles Railway Company has subscribed $5,000, and the Los Angeles Traction Company $1,000 to the fund for the erection of a convention hall at Los Angeles.

SAN FRANCISCO, CAL.—An appeal has been made by W. T. Baggett, representing the Bay & Coast Railway Company, to the street committee of the board of supervisors for passage to print of an ordinance granting the company a franchise to enter San Francisco. The route described in the application is from the county line, south of Ingleside, thence irregularly in a northeast direction to Islais Creek and thence through San Francisco and the Potrero to the Mission.

HARTFORD, CONN.—The residents of Hartford were treated to an exhibition of baseball between teams representing the Hartford Street Railway Company and the Hartford police department on July 18. Six innings were played, and the score stood 25 to 5, in favor of the police.

HARTFORD, CONN.—The employees of the Hartford Street Railway Company gave a dance at the Casino last week. Before the dance the Street Railway Band gave a concert on the green, which was enjoyed by a large number.

COLUMBUS, GA.—The employees of the Columbus Railroad Company, both railway and lighting departments, enjoyed a barbecue on July 13 tendered by President Flournay of the company. The affair occurred at Mr. Flournay's home in Wynnton, and was thoroughly enjoyed by all.

ATLANTA, GA.—As the result of a caucus between members of the City Council an entirely new electric lighting franchise has been adopted in favor of the Atlanta Railway Company. The franchise is given for a period of twenty-five years.

EAST ST. LOUIS, ILL.—An extension of time has been granted the East St. Louis Electric Railway Company to lay tracks in certain sections of the city. In consideration of the grant of further time the company agrees to pay $9,789 to the city, which amount will be returned to the taxpayers who paid for the elevation of the street. For this work the company was not taxed, as it had rails laid on the street.

CHICAGO, ILL.—The annual meeting of the stockholders of the Chicago Union Traction Company was held July 24. The old board of directors was re-elected, but the meeting of the board, for organization, was postponed until next week. The company reports the income account for the year ended June 30, 1900, as follows: Gross earnings, $7,477,398; operating expenses, $3,761,797; net earnings, $3,715,601; other income, $868,351; total income, $4,583,951; total deductions from income, $3,979,876; balance $604,076; dividends on preferred stock, 5 per cent, $600,000; surplus, $4,076. Following are particulars of traffic: Car mileage, 29,691,850; passengers carried, 20,849,562; per cent of transfer passengers, 38.71 per cent; proportion of expense to earnings, 50.31 per cent; proportion of expense to gross receipts, 45.07 per cent; proportion new income to gross receipts, 7.24 per cent.

CHICAGO, ILL.—President J. M. Roach, of the Union Traction Company, was waited upon by a delegation of seventeen of the oldest employees of the North Side street railways at his office last week. The men presented him with a roll containing the names of nearly 2000 employees, who wished to express their thanks for the recent raise in their salaries. The list was headed by the following greeting: "We, the undersigned employees, appreciate the stand you have taken in the matter of wages, and take this means of conveying to you our appreciation and to express our heartiest thanks. We wish to assure you that as far as we are concerned your efforts in our behalf will not be wasted, and the future shall prove that no man has a more loyal set of men in his employ than you have."

Mr. Roach assured the committee that he would look after the interests of the men, and do for them anything within reason. The recent rise in wages, he said, was not final. If the men should act in such a manner that a saving to the company would result, it would assuredly result in profit to them, and if at any time they had any suggestions to offer for the betterment of the service and the better care of the public he would be pleased to hear from them.

ELKHART, IND.—The Indiana Railway Company, which owns the local electric lines at Elkhart, Goshen, Mishawaka and South Bend, and the interurban line between the towns, is preparing to establish a baggage system on the interurban lines.

INDIANAPOLIS, IND.—The Indianapolis Street Railway Company has purchased both the Martinsville gas and Commercial electric lighting plants. The plans of the company, in regard to this purchase, are not known.

SHELBYVILLE, IND.—On July 17 the City Council passed an ordinance extending the franchise granted March 20 to the Shelbyville Heat, Light & Power Company 240 days. The company has experienced considerable difficulty in securing other franchises for its new line, and this has prompted the Council to grant an extension of time for beginning construction work here.

WICHITA, KAN.—Arrangements have been completed between the Wichita Electric Railway & Light Company and the promoters of the carnival for displaying similar floats on the street car lines to those which made such an impression in Milwaukee and New Orleans. The subject of the floats will not be given out until the carnival week.

LOUISVILLE, KY.—The franchise for operating a street railway on Frankfort Avenue, from the old city limits to the new limits, a distance of 5860 ft., has been sold to the Louisville Railway Company for $250.

WEBSTER, MASS.—The Railroad Commissioners are inquiring into the causes of the accident here on July 4, so as to determine who was responsible for the catastrophe.

SPRINGFIELD, MASS.—The Selectmen of Agawam, Mass., have dismissed the petition of the Hartford & Springfield Street Railway Company for permission to lay tracks in the streets of the town. The Hartford & Springfield Street Railway Company is a Connecticut corporation and recently succeeded to the rights of the Springfield & Southwestern Street Railway Company, under the charter of the Suffield & East Granby Street Railway Company, and the name of the company was changed to the Hartford & Springfield Street Railway Company by permission of the Superior Court of Connecticut.

DETROIT, MICH.—A resolution has been introduced in Council by Alderman Beamer requesting that the street railway company consider the acceptance of a new thirty-year franchise covering all lines in the city with the general rate of fare to be eight tickets for 25 cents, with universal transfers. Governor Pingree, the advocate of municipal ownership, says: "On the face of it the proposition may be considered the next thing to municipal ownership."

ST. LOUIS, MO.—It is reported that the St. Louis & Illinois Electric Railway, which wants a franchise in St. Louis, and has a bill pending in the City Council, will be a rival to the St. Louis Transit Company. It is said that it will connect with the electric and steam railways east of the river. It is also rumored that the St. Louis & Suburban will be taken into the combination.

LIBERTY, MO.—The organization of the Kansas City, Liberty & Excelsior Springs Railway Company has been perfected, and it is stated that work on the construction of an electric line between the points named will begin soon. The officers of the company are: J. S. Chick, president; Charles H. Scott, vice-president; C. B. Leavel, secretary; J. P. Bauserman, treasurer, and Charles L. Leiteh, chief engineer. Surveys are expected to be made at once to select a route. The capital stock of the company is $1,000,000.

OMAHA, NEB.—At a recent meeting of the City Council the Omaha, Council Bluffs & Suburban Railway Company was granted permission to lay several additional short lines.

EXETER, N. H.—An innovation is being planned for Hampton Beach in the shape of Sunday services to be held in one of the Exeter, Hampton & Amesbury Street Railway Company's buildings. A prominent religious worker has broached the subject to Superintendent McReel, and he has granted the free use of the building and the piano to any clergyman who desires to start the movement.

CAMDEN, N. J.—The Camden & Suburban Railway Company has made application to the Council of Riverton for permission to construct an electric railway on Broad Street, in that borough, to connect with the company's line in Palmyra, and with the lines of the Camden & Trenton Street Railway Company. The Council has decided to consider the application on Aug. 9.

BROOKLYN, N. Y.—Alfred R. Goslin, Charles Thomas Davis and Eugene L. Packer, who were convicted recently of conspiracy to "bear" the stock of the Brooklyn Rapid Transit Company, have obtained from Justice Bischoff, in the Supreme Court, a certificate of reasonable doubt as to the legality of their conviction, in order that an appeal might be taken. Justice Bischoff fixed bail for Goslin, who was sentenced to six months in the penitentiary and to pay a fine of $500, at $12,000; and for Packer and Davis, who were each sentenced to three months' imprisonment and a fine of $250, at $5,000 each.

NEW YORK, N. Y.—A Third Avenue trolley car became unmanageable in Park Row July 18, and smashed into the rear platform of a horse car of the Dry Dock, East Broadway & Battery line. The platform was squashed like a crushed strawberry box, the car pitched onto the sidewalk and two passengers painfully bruised. A wheel was taken off a wagon standing nearby, and the driver was thrown into the street. The collision threw the horses of the horse car against an electric car in front, and one of them was crushed to death.

BROOKLYN, N. Y.—An accident occurred on a siding of the Kings County Elevated Railroad at Georgia Avenue and the Eastern Parkway July 17, in which three empty cars were hurled from the track into the street and wrecked. The accident was caused by some misplacement of the switch.

BROOKLYN, N. Y.—At 6 p. m. on July 19 the Rockaway express of the Long Island Railroad ran into the Bay Ridge elevated train on the Fifth Avenue branch of the Brooklyn Elevated near the Fulton Street station, killing the motorman and injuring several passengers. The Bay Ridge train was stalled, owing to the fact that the fuse on the rear car burned out, and no warning was given to the Long Island train, which followed at a headway of five minutes. None of the injured were seriously hurt.

ALBANY, N. Y.—At the annual meeting of the stockholders of the United Traction Company, held last week, the retiring officers were re-elected, and in addition J. W. McNamara was elected second vice-president. The directors also declared a regular quarterly dividend of 1¼ per cent, payable Aug. 2. The total earnings for the six months ending June 30 are $640,000, considered a handsome showing for the first half year of the new consolidated company. On the basis of these figures the aggregate earnings for the year are placed at $1,400,000.

STATEN ISLAND, N. Y.—Thirty passengers in a trolley car of the Staten Island Midland Railroad Company's line jumped or were thrown in a heap upon a macadam roadway at Concord, S. I., on July 17, and many were hurt. The car was descending a short but sharp grade in Richmond Road when it left the rails. It jumped a deep gutter, climbed the bank at the right side of the roadway, just missed a big telephone pole and crashed through a high board fence. The car ran diagonally up the embankment and when its impetus was checked settled back and careened toward the roadway, almost overturning. The passengers, men, women and children, were badly frightened, and as the car threatened to overturn they jumped or were thrown out into the roadway.

Street Railway Journal

VOL. XVI. NEW YORK AND CHICAGO, AUGUST 4, 1900. No. 31.

RECENT IMPROVEMENTS IN THE SOUTHWEST MISSOURI ELECTRIC RAILWAY SYSTEM

Since the publication of an article on this system, in the STREET RAILWAY JOURNAL of May, 1899, extensive improvements have been made, which warrant a rediscussion of this interesting interurban proposition. About $300,000, raised by second-mortgage bonds, has been expended during the last year on extensions, double tracking, new car houses, and particularly on a new power plant and complete polyphase system of distribution with rotary converter sub-stations.

The line of the Southwest Missouri Electric Railway Company connects and runs through the cities of Joplin, with a population of 30,000; Webb City and Carterville, with a combined population of 15,000, and Carthage, Mo., with a population of 12,000, and Galena, Kan., with a population of 15,000, by far the greater part of its traffic being interurban. The country through which the road runs is highly cultivated farming land on the surface, thickly dotted with the head houses of the zinc mines for which Joplin and Galena are noted. These mines employ many men in their underground workings. This unusual double occupation of the land gives a correspondingly large passenger traffic. The line is 31 miles long, about 20 miles of which is on private right of way, 50 ft. in width. The roadbed is laid out on standard steam railroad plans, the rails being laid on 6-in. x 8-in. x 8-ft. oak ties, laid 2 ft. between centers. All the new rail is 60-lb. T, made by the Pennsylvania Steel Company, in 60-ft. lengths.

The line is favorably situated with regard to securing ballasting material. The piles of tailings from crushers of the zinc mines, between which the road twists and turns in places, consist of a coarse, dustless, crushed flint rock, which makes as good a ballast as broken stone. It drains nicely and weeds do not grow upon it. The line is shouldered and ditched through the cuts. Of the total length of about 31 miles, approximately 8 miles are double tracked, nearly all of this double tracking having been put in during the last year; the double-track sections are being extended as rapidly as circumstances will permit. The line is laid out to obtain as long tangents as possible,

CAR HOUSE AT WEBB CITY, SHOWING STANDARD TYPES OF CARS

grades being permitted to avoid curves to a greater extent than in steam railroad practise, as electric cars—if supplied with good voltage—can go over the grades without difficulty, while curves necessitate slowing down and introduce greater possibilities of accidents. The speed

EXTERIOR OF POWER STATION

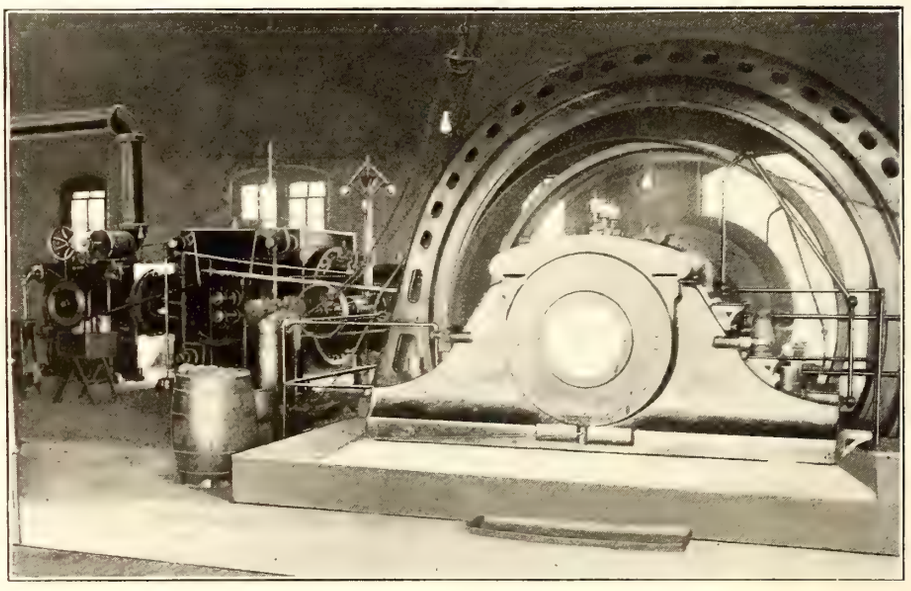
obtained is consequently comparable with that of steam lines.

From Joplin to Carthage, Mo., a distance of 19 miles, there is run what is termed the "Empire County Express." This car makes four intermediate stops for passengers and five stops for railroad crossings. It is scheduled to run 19 miles, with a total of ten stops, in one hour, and makes the schedule with great regularity. This express runs at intervals of one hour and a half, there being six local cars at thirty-minute intervals between the expresses, thus giving frequent service. The local cars take nearly one-half hour longer than the express to make the run, so that an express starting five minutes ahead of a local nearly overtakes the local ahead before reaching its destination. In the other direction, from Joplin to Galena, a twenty-minute service is given.

The rates charged are about 1 cent per mile, the fares being 10 cents from Joplin to Galena in one direction, or Webb City, in the other, and 10 cents from Webb City to Carthage. A book of one hundred 5-cent fares is sold for $4.50. There is being waged a sharp competition by the steam road operating between the same points, which is now giving the same rates as the electric line. Some freight is carried on the front platforms, but no effort is made to obtain it. Between Joplin and Carthage, 19 miles, which the Empire County Express (electric) makes in one hour, the steam road is scheduled to run in fifty minutes. The steam road, however, is handicapped by its inability to reach the business centers. In Carthage, as well as in Webb City, a free bus is operated by the steam road, which enables passengers to get to and from the trains. The frequency of the steam service is two hours from Joplin to Carthage, as compared with every hour and a half on the electric express and every thirty minutes on the electric locals.

Eighteen cars are usually in operation, all of which are double truck, there being no value in single-truck cars for this class of service. The cars have unusually wide bodies, 8 ft. x 4½ ins. maximum, and an exceptionally large amount of steel in their framing, as called for by the rigid specifications, a reprint of which will be found on another page of this issue. The cars have cross seats and smoking compartments in most all cases. The cars were made by the Laclede Car Company and Jackson & Sharp, and are mounted on Brill No. 27 G and Jackson & Sharp trucks, some Peckham trucks being also used. No small-wheel maximum-traction trucks are used, owing to the comparatively easy riding of the uniformly sized larger wheels and the high speed. The cars are equipped with two motors each, Westinghouse 38 B and General Electric 57's being used, geared up to 31 miles per hour at 500 volts; they get, however, about 600 volts. The weight of each car is kept down to about 18 tons, so that two motors can handle the work easily. Sufficient maximum-traction effect is obtained by overhanging the motor at one end of the truck, instead of mounting it between the wheels.

The cars are fitted with Wagenhals' inclosed arc headlights. These headlights are adjusted for 6½ amps., and throw an astonishingly brilliant searchlight beam along the track in the dark country districts. Their use is found to be of great benefit in reducing the number of cattle killed at night, the brilliant beams of light serving not only to show up cattle on the track, but to frighten them away. While without the arc headlights more cattle were killed during the evening than during the day time, this condition is now reversed. The head-lights do not seem to frighten horses, as might be expected. The head-lights are wired in the motor circuits, thus obtaining their current through the circuit breakers, with which every car is provided. To avoid blinding the motorman of an approaching car, the lights are turned off by tripping the circuit breaker and pulling out the plug which supplies current to the light. In this way arcing at the plug is avoided. Curtains are drawn in the front doors of the cars to darken the platform and further enable the motorman to see ahead on the track.

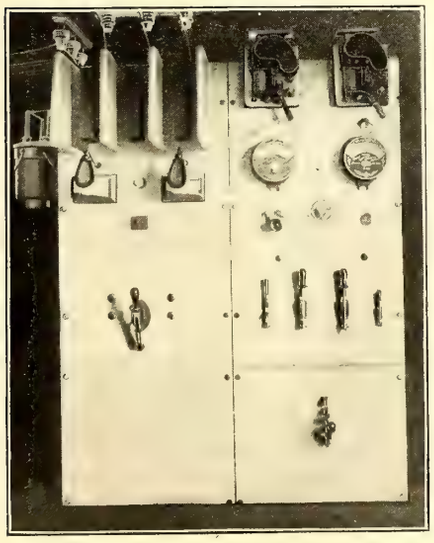


INTERIOR OF POWER STATION, SHOWING 1200-HP UNIT

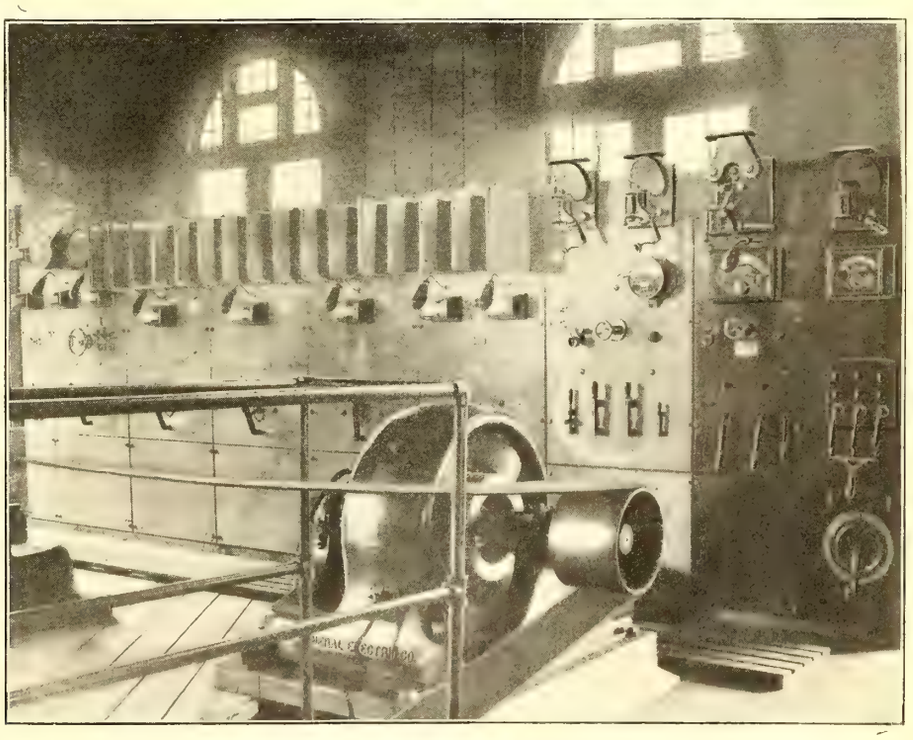
The work on the new power plant was begun in September last, previous to which time the road was operated by two direct-current plants, the long feeds being carried by means of boosters. The polyphase equipment was first put in service April 25. The direct-current apparatus was

very heavily loaded, and in spite of this fact the new polyphase generating system was set up in place of old engines and generators in one of the existing plants, new boilers were installed in the places occupied by the old, and service was maintained while the changes were being carried out. This was almost as difficult an undertaking as the alleged proposal of a Southern Board of County Commissioners to erect a new court house in place of the old, to use the materials of the old in the construction of the new, and to occupy the old house until the new one was finished. The power house not changed over is now maintained as a reserve, but is not operated, the polyphase system carrying the whole load. In laying out the polyphase system the rather unusual principle has been followed of putting in no reserve units in the original installation, thus making all machines of as large a capacity and of as economical a size as possible, future extensions being depended upon to call for duplicate and reserve machines. Thus the original installation has only one engine, one generator, one exciter, one high-tension line in each direction, and one rotary converter in each sub-station. The adoption of such a policy in place of the usual use of at least two, and generally three, units, common until lately, speaks well for the improvement in reliability and freedom from shut down of power-house machinery. The new generating equipment consists of one tandem compound horizontal Cooper-Corliss side-crank engine, rated at 1200 hp, driving at 95 r. p. m. one 32-pole, 25-cycle, revolving-field three-phase generator. To avoid oscillations and hunting of rotary converters with a single-crank engine, there is fitted to it a 55-ton fly-wheel, 18 ft. in diameter, with a cast iron rim having a cross section 18 ins. square. The engine is guaranteed to use no more than 14 lbs. of steam per ihp-hour at its rated load. The generator, as well as the whole of the polyphase equipment, was built by the General Electric Company. The generator is wound to deliver the full high-tension pressure of 11,000 volts directly from its windings, thus doing away with the need of step-up transformers. It is rated as able to carry 750 kw with a 90 per cent power factor, *i. e.*, it will carry its full rated output of 750 kw without overheating, even if the current lags behind the e. m. f., due to reactance in the circuit, to such an extent that the current is necessarily increased 11 per cent above what would be necessary with a non-inductive load. The generator is guaranteed to carry its rated load continuously with a temperature rise not over 40 degs. C. above the air at 25 degs. C., and to carry a 25 per cent overload for two hours with a temperature rise not exceeding 50 degs. C. The guaranteed efficiencies are 95 per cent at full load, 94 per cent at three-quarters load, and 92 per cent at half load. The

TYPICAL INTERURBAN TRACK VIEW



SUB-STATION SWITCHBOARD



MAIN STATION SWITCHBOARD

guaranteed regulation is a rise of voltage of 8 per cent on throwing off full non-inductive load.

Three new double-decked Cahall boilers, each rated at 450 hp, have been put up with chain-grate stokers built by the makers of the boilers—the Aultman-Taylor Company. Coal and ash handling apparatus, coal bunkers and a new

INTERIOR OF SUB-STATION

chimney will be built later. Good feed water is obtained from a driven well 825 ft. deep, in which the water rises to within 75 ft. of the surface, from which level it is raised by a deep-well pump. Otherwise, it is a difficult matter to obtain good feed water in this locality, as the mines discharge considerable acid into the stream. A Cookson feed-water heater is used. The engine exhausts into a Worthington condenser, the water for which is cooled in

TYPICAL SUB-STATION, COMBINED WITH RESIDENCE OF ROTARY ATTENDANT

a Worthington cooling tower of the forced-draft type. This tower, which appears in one of the illustrations, is 17½ ft. in diameter and 34 ft. high, built of boiler plate, and is guaranteed to handle 21,000 lbs. of steam per hour, giving a vacuum of 24 ins. to 26 ins. The 108-in. fan of the cooling tower is driven by an old S. R. G. 30 motor, with suitable gearing.

The switchboard of the generating station is of the usual General Electric high-tension form, with type G oil switches and spring-expulsion type fuse holders. General Electric electrostatic ground detectors are used, connected in series with carbon rod resistances to prevent a short circuit in case the voltage jumps between the vanes of the ground detectors.

From the station two high-tension feeders run out in opposite directions along the track, as indicated in the wiring plan. One of these is of No. 4 wire as far as the first sub-station and No. 6 wire the remainder of the distance to the second sub-station in the same direction; the other is No. 6 wire from the station to the only sub-station in that direction. The high-tension lines are carried on Locke 5½-in. triple-petticoat insulators on the poles which support the span wires. The high-tension wires are on one side of the road, clear of the feeders and telephone line, which are kept on the other. The central power station itself contains a sub-station equipment, thus making four sub-stations altogether. Two 0000 feed wires are

MAIN OFFICES OF COMPANY

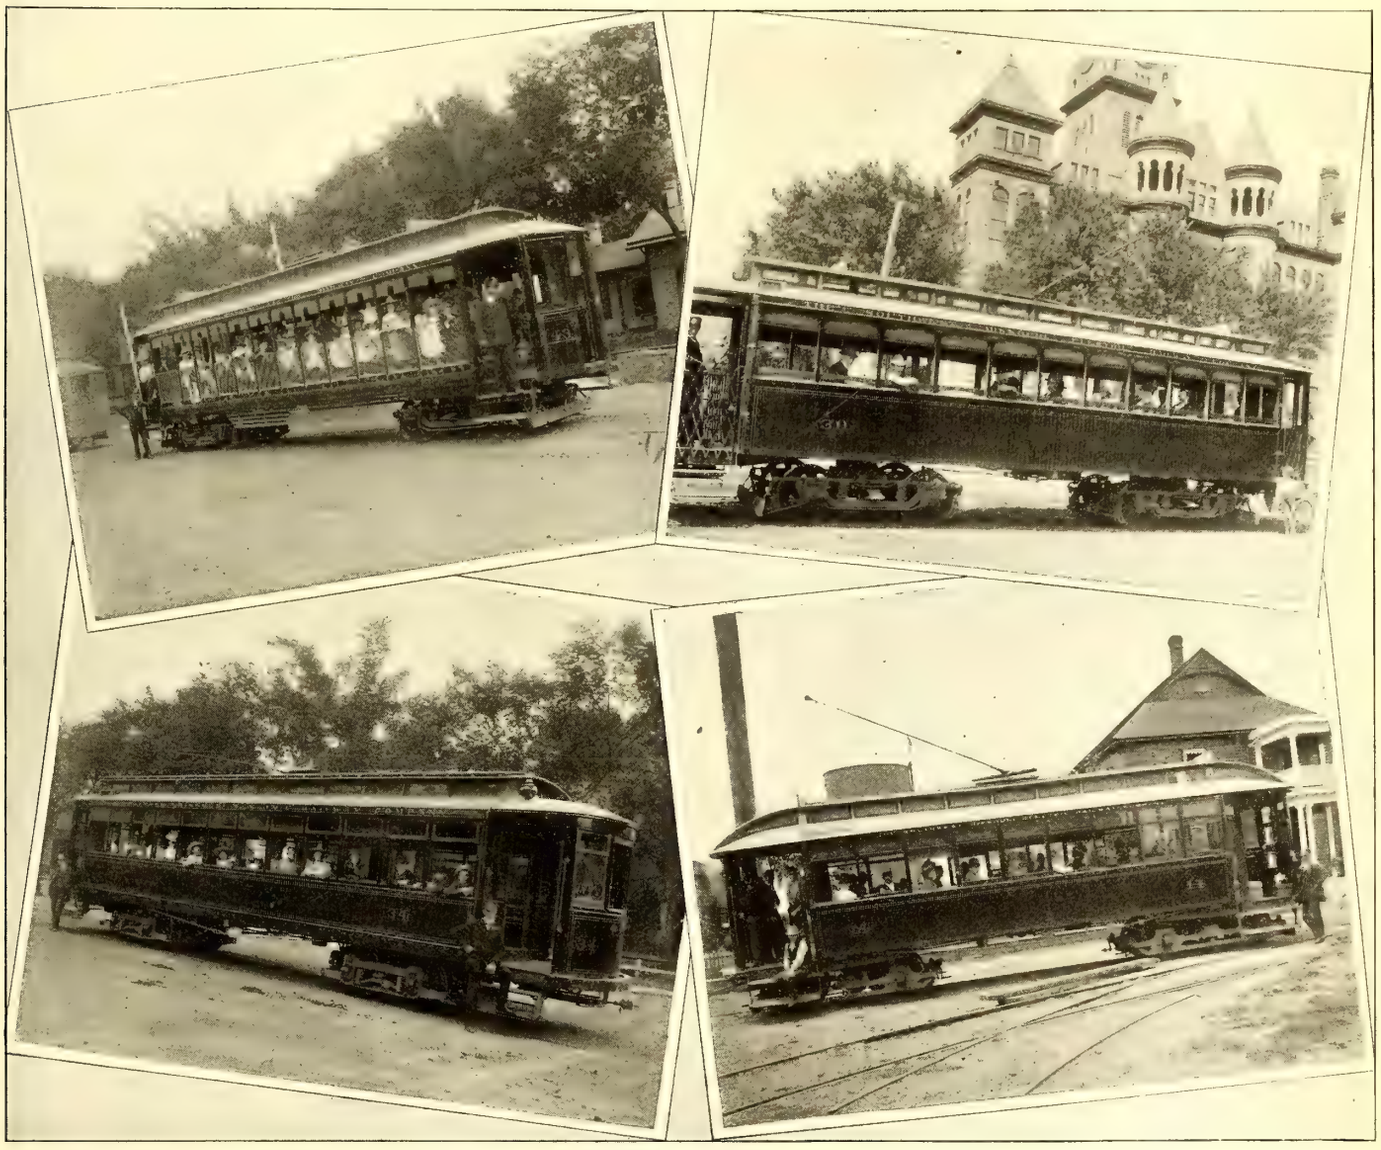
carried throughout the whole length of the line as a sort of side feeder. The company now has considerable unused feed wire on its hands, owing to the greatly reduced amount of copper necessary with the new system feeding 500-volt lines at all points. In front of the central power station the trolley line is divided by section insulators and the 0000 feed wires going to each direction are brought into circuit breakers on the board, so that either half of the line can be shut down and service continued on the other half in case a wire is down or there is a heavy thunder storm on one section. The sub-station switchboards are also fitted with two feeder breakers, so that the electrical continuity of the line can be interrupted for the same purpose in front of the sub-stations by putting in section insulators if at any time it is found desirable.

The sub-station equipments are in all cases the same. The apparatus consists of one 250-kw rotary converter supplied by three 80-kw oil-insulated, oil-cooled, step-down transformers, thus doing away with blowers and their motors, which are necessary with the forced-draft type of transformers. No copper bridges or equivalent devices for reducing hunting are used on the rotaries, although they are supplied from a single-crank engine running at only 95 r. p. m. In spite of this, there is no

trouble whatever from hunting, the alternating ammeters showing only the slightest perceptible beat in time with the engine strokes. Although the rotaries are rated at 417 amps., 900 amps. have been drawn from one of them for a short period without sparking and without overheating. The rotaries are compound wound, and, with the exception of the machine in the central power station, are oil insulated and air cooled. Reactive coils have been put in the alternating circuits to give the proper compounding.

The method of starting the rotaries is as follows: When starting up in the morning the main generator is run up to about half voltage, and the rotary in the main power station is thrown on and started up by the induction motor rheostat switch is installed on each rotary switchboard for this purpose.

The sub-stations are attractive appearing structures of the style illustrated herewith. The interior is largely given over to the living quarters of the sub-station attendant and his family. By combining the residence and the sub-station proper in this way but one man is needed per sub-station, as other members of his family are capable of watching the apparatus in his absence. The one room devoted to the electrical apparatus is provided with a double door sufficiently wide to accommodate the rotary, and the sub-stations are so planned that this room can be extended when more machines are needed.



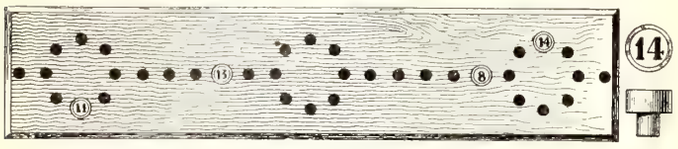
STANDARD OPEN AND CLOSED CARS

action of the alternating currents; that is, by the method usually adopted with General Electric apparatus; the half voltage of the generator serves the same purpose as compensating transformers, reducing the alternating voltage impressed on the collector rings of the rotary down to about half the normal. When synchronized and brought up to full pressure, the direct-current end of the power-station rotary is closed on the 600-volt lines and the sub-station rotaries are started from it by means of direct current sent out over the trolley wires and 0000 side feeders, which, as noted above, are continuous from station to station. In this way the sub-station rotaries are brought up to speed without using alternating currents. A four-step

Among the other extensions during the last year are the new car house and shops, a view of which appears herewith. This building has a frontage of 143 ft. and is 200 ft. long, affording accommodation for forty cars. It is located just across the track from the power station and general office in Webb City. In it the cars are cleaned and all repairs are made. The company does not allow the use of any water in cleaning its cars, Modoc liquid car cleaner, made by the Modoc Soap Company, of Cincinnati, Ohio, being used exclusively.

A view of the general office of the company is also given. The lower floor contains the usual general offices, and the upper floor the dispatcher's office, the dispatching being

done, as usual, by means of a telephone line with bridging stations of the police-patrol type. The phone dispatcher has in front of him a board with holes arranged as in the accompanying sketch, in which he can insert buttons numbered to represent the cars, so as to keep track of their locations on the line.



BOARD USED BY TRAIN DISPATCHER FOR RECORDING LOCATION OF CARS

Another interesting point about the operation of this system is the method of paying the men. The rate paid conductors and motormen is 12½ cents per hour during the first six months, after which 15 cents is paid, with an addition of what is termed a "10 per cent dividend," *i. e.*, each man is paid at the end of six months a further sum equal to 10 per cent of his total wages during the previous six months' period. In this way the amount actually paid is 16⅔ cents per hour, provided a man does not leave during the six months.

On July 4 the company made an innovation which perhaps is worthy of mention. On that day it was decided to dispense altogether with the use of fare registers. Instead, each conductor reported the amount of cash he had on hand in the morning of the 4th, put in the entire day and a good part of the night in collecting fares, not registering any of them, and then turned in amount of cash on hand at close of business, less amount he started with in the morning. The experiment was successful, and the total receipts for the day were $530 in excess of any previous day in the history of the road. One conductor turned in $196.20, which is the record for the road; all of this was collected from one car with no trailer.

The Southwestern Missouri Electric Railway Company is capitalized at $800,000, all of which is issued, and has an authorized bond issue of an equal amount, of which $750,000 is issued, the bonds drawing 6 per cent and being redeemable inside of three years. The receipts for the month of May, 1900, the last month previous to the writing of this article, amounted to $22,593, of which the operating expenses, including paving, car licenses and legal expenses, amounted to $9,647, leaving a net income of $12,946. The interest on the bonded indebtedness amounts to $3,750 per month. Occasional dividends have been paid in the past, and from now on regular dividends will be paid, although at the time of this writing the amount of these dividends was not decided. The stockholders of the road are identical with the bondholders, and are largely residents of Harrisburgh and Philadelphia, Pa. The road has an Eastern office in the former place.

The president and treasurer of the road, A. H. Rogers, manages its affairs, taking personal charge both of its larger and more important dealings and the many details of operation. To President Rogers is due the credit for the road's good equipment, successful operation and pros-

perous condition. The other officers of the road are as follows: E. J. Pratt, superintendent motive power; C. E. Baker, superintendent transportation; J. M. Maret, superintendent tracks, lines and bridges, and H. T. Morrison, superintendent repair shop.

The Street Railway System of Geneva, Switzerland

The beautiful city of Geneva, situated at the western end of Lake Leman, has of late become more than usually interesting to the American tourist and engineer, by reason of the remarkable change that has been made in its street railway system. In view of the size and importance of the city and the extent to which all the facilities for travel are liberally patronized, it is a little curious that the initiative in the new work should have come from outside; but this has also occurred elsewhere in Europe. Geneva was early in the possession of steam tramway and trolley roads, but it has been reserved for foreign capitalists to unify the existing systems, create a most extensive network of new lines, and to develop plans which comprise not only the whole canton, but all the adjacent country in Switzerland and France that is physically part of Genevese territory. The past month has witnessed the completion of a large part of the enterprise, giving, therefore, an opportunity for presenting the work and its history in more or less appropriate detail.*

BRIDGE OF MT. BLANC, AN ARTERY OF STREET RAILWAY TRAVEL, GENEVA

It would appear that about three years ago H. E. Butters, of San Francisco, prominently identified with Californian and South African mining interests, was very much impressed while passing through Geneva on a tour, with the fact that the street railway service was not adequate to the population, and that with abundant cheap water power in the city itself, the methods employed depending largely on steam "dummies," were intolerably behind the times. The idea immediately suggested itself to Mr. Butters to effect improvement by consolidation and the injection of new capital. Steps were at once taken to this end, outside capital was readily enlisted on a rough presentation of the plan, and ultimately control was obtained of the Narrow Gage Street Railway Company (Voie Etroite) of Geneva, with nearly 45 miles of track in the city and suburbs, and of the General Company of Swiss Tramways (Compagnie Générale des Tramways Suisses), operating about 22 miles of track in the best parts of the city. The parties thus becoming interested, namely, the General Tramways Construction Syndicate, Ltd., of 43 Threadneedle Street, London, also secured a federal charter for the Genevese Company of Electric Tramways (Compagnie Genevoise de Tramways Electriques), and with it concessions for new lines of nearly 18 miles in and around the city and some 14 miles in extensions each side eastward of the Lake of Geneva to the charming suburbs of Versoix on the Swiss shore, and Hermance, at the French border. The Compagnie Genevoise has already done a large part of its work in welding together the system thus created, which serves a city of about 100,000 souls; a canton with a population of 120,000 and an area of 109 square miles, and which is reaching out necessarily to annex or associate with itself lines that ramify in every direction in territory hitherto dependent chiefly upon slow and expensive steam locomotion. A map is shown herewith of the Genevan network of the company, presenting graphically the manner in which, with an expenditure when all is done of about $5,000,000, the old and new lines thus consolidated and amounting to nearly 100 miles will cover the city and its suburbs, and will furnish a first-class modern system with all the improvements that the most skillful engineering can suggest.

It was natural that those who had undertaken this great enterprise should look to America for the expert ability to direct and supervise the expenditure of their money, and thus it came about that Stephen D. Field, so well known in the United States, not only as a brilliant inventor, but as one of the oldest electric railway engineers in the country, was invited to take the position of engineer-in-chief. This he consented to do, and associated with himself A. Kundig, a young Swiss engineer, who had had considerable experience in America. Under the vigorous and efficient management of these two men an amount and quality of work has been done in a manner and at prices

* Illustrated articles on street railway work in Geneva appeared in the STREET RAILWAY JOURNAL for February, 1897, and November, 1898, and they contain detailed information as to the older systems which it is not necessary therefore to repeat here.

that are simply amazing, and it may fairly be questioned whether there is in all Europe a system that has been more liberally, yet more economically, constructed. Preliminary to any attempt to consolidate car houses, rolling stock, etc., the Compagnie Genevoise determined to establish its own headquarters, and this it has done at a most picturesque part of the city, in the southwest, at a point called La Jonction, just where the blue Rhone from Lake Geneva and the arrowy, turbid Arve, from the Mount Blanc ranges, mingle their waters and flow southward to the Mediterranean. Herewith are shown views of the property and buildings, with a plan of the offices, car house and machine shop, as at present developed. The company owns at this spot about 20,000 sq. m., and thus has ample provision for the inevitable growth. As a matter of fact, this little real estate investment has proved one of the best of the concern's many shrewd moves, for the river detritus taken out and crushed electrically for roadbed material has pretty well covered the price. As is usual in Europe, the office building is a handsome, substantial edifice. It is three stories in height, with clock tower, and is built of a rich French white stone, upon which ornamental carving has been freely bestowed. It has a frontage of over 115 ft. and a depth of nearly 120 ft. in an L shape. The ground floor is devoted to the offices for cashier and bookkeeper and general accounts, and to an

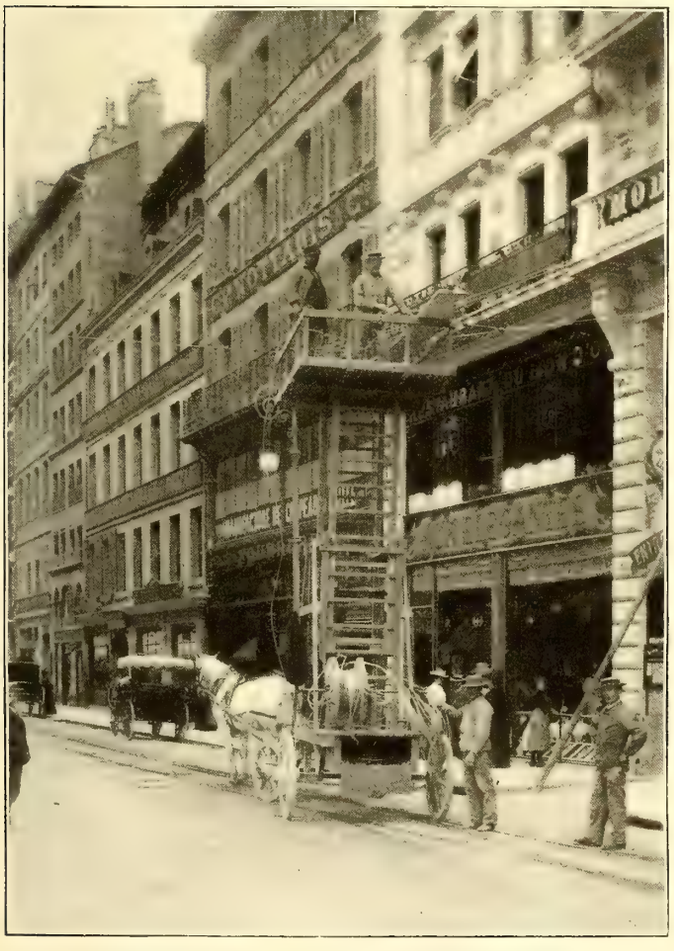
LAYING TRACK ALONG ROUTE D'HERMANCE, NEAR PARK DES EAUX VIVES

LA JONCTION, HEADQUARTERS OF THE CIE. GENEVOISE DE TRAMWAYS ELECTRIQUES

CHEVRES POWER STATION, GENEVA

assembly room for the motormen, while the long wing of the building carries a large stock of supplies, for which there is also a commodious basement. The first floor is occupied by the management, with rooms for the superintendents and various officials, and a large board room for the directors and receptions. The second floor is reserved for the engineering department, and has excellent light, and there are also a salon, bath, dormitory, etc. In the clock tower an archive room for files, etc., has been placed.

Closely adjoining the office building is the car house, of steel and brick construction, the face of the bricks being covered with hard cement. It is about 275 ft. long by 80 ft. wide, has six tracks, and can be added to indefinitely as to width. It will now carry fifty 18-ft. cars, and the pit has been made clear across the lower end, so that no switching is necessary to get cars over it. Immediately in the rear is a fine machine shop and repair shed at right angles to the car house, with one of its sides on the bank of the River Rhone. It is of the same general construction as the car house and is nearly 200 ft. long by 60 ft. wide. It is equipped with a 15-ton traveling crane and the necessary complement of tools. The yards outside the buildings



RUE DU RHONE, OVERHEAD CONSTRUCTION

constitute a depot for heavy material, such as poles, rails, road material, etc.

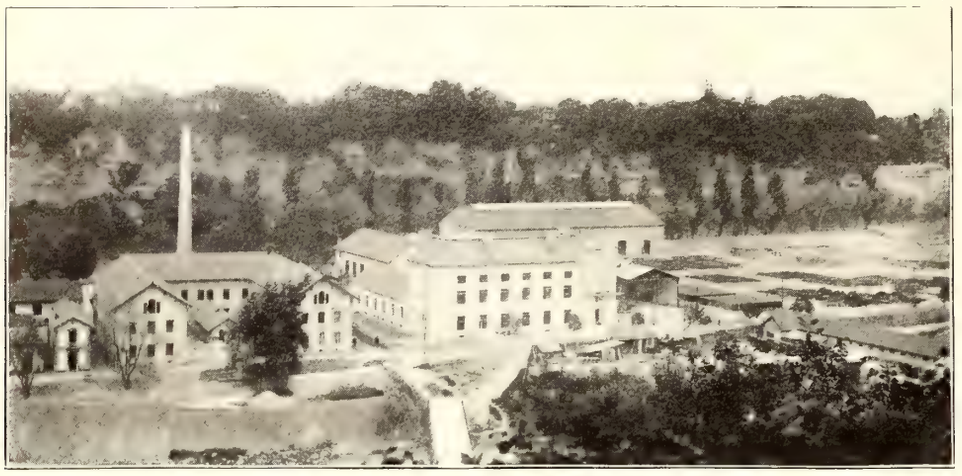
It is probably well known that the gage of street railway favored in Switzerland is only 1 m. (3 ft. 3 ins.), called the Voie Etroite. In Geneva, when the new company came into power, there were about 45 miles of such gage in the city in operation and about 18 miles of medium gage. All the new work is of 1-m. gage, which, of course, becomes therefore the standard of the whole system. Mr. Field and his staff are thoroughly well satisfied with this width, which has its advantages in view also of the narrowness of many of the streets traversed, and Mr. Field has even worked out a novel type of car known as the Hotel de Ville, from the section in which it will run and which is intended to go through narrow streets rather than wreck or abolish the existing architecture. It is only 1.70 m. in width, seats

LAYING CONDUIT ALONG ROUTE D'HERMANCE

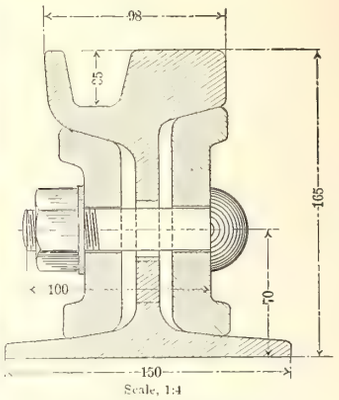
eighteen people, and provides standing room for eight more. But the standard size of car, which will doubtless be generally adhered to, is 2 m. (6 ft. 6½ ins.) in width over all, although it can be made 2.20 m. (7 ft. 2½ ins.) and keep within the official requirements and conditions. The company has thirty-six existing cars and is adding ninety new ones, for the electrical equipment of which Westinghouse motors and controllers will be used, of the familiar type. The new cars are being furnished by the Societé Industrielle Suisse, of Neuhausen, Schaffhausen, and some were equipped by the Basle works of the Allgemeine Elektricitäts Gesellschaft. The charter of the company, it may be fitly mentioned here, requires broadly that all materials and supplies used shall be preferably of Swiss origin or bought through Swiss houses. The engineers of the road are very much in favor of the Brill type of car, as used in California and also at Capetown, and one of these was actually imported by special permission to serve as an object lesson to the Genevese, who have been very enthusiastic about it, and apparently would like all the rest to be of the same comfortable and commodious model. Each car has two 25-hp motors, with ordinary controller, and is furnished with two series of five incandescent lamps of 110 volts, and is heated in addition with the McElroy electric heaters of the Consolidated Car Heating Company, of Albany, N. Y.

The rail used by the Compagnie Genevoise is the Phœnix, model 18 C, furnished by the firm of Demierre & Company, of Geneva. It is shown herewith in cross section, and has a weight for city use of 105 lbs. For country

lines the Phœnix model 5 F is used, with a weight of between 65 lbs. and 70 lbs. All the angle-plates have three bolts on either side of the joint, and the Edison-Brown plastic bond is used, with three or four 00 copper wires at



OFFICE, CAR HOUSE, ETC., AT LA JONCTION



STANDARD SECTION OF RAIL

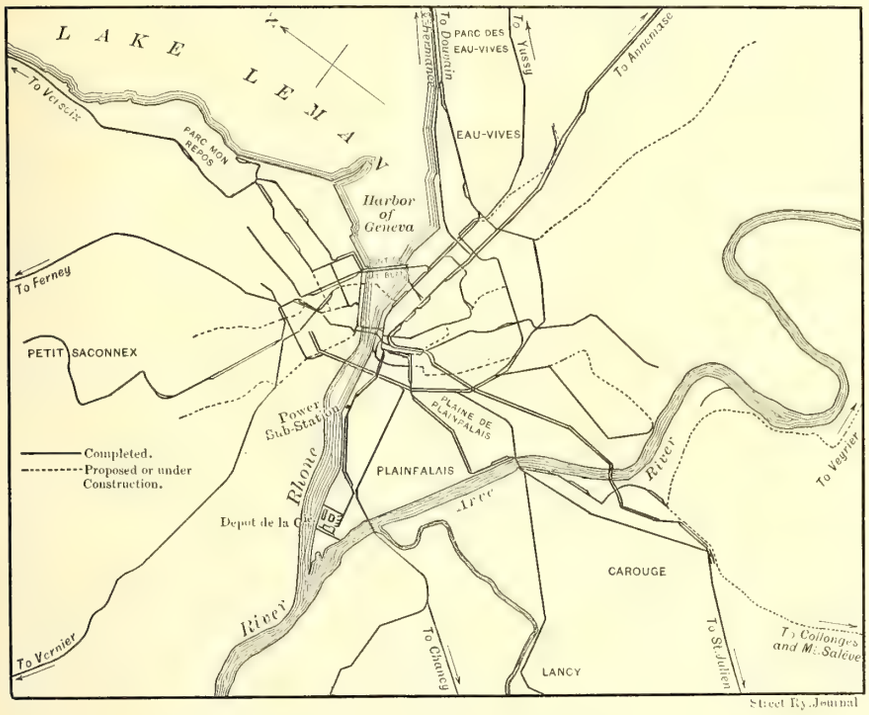
crossings. The nature of the track and roadbed construction can be seen from the views presented. All the track in the city is carried on concrete girders, with a height of 12 ins. and a breadth of 10 ins., while the total depth of masonry under the track is 1 m. This solidity is not only due to the fact that the bed has to stand the crushing strain of the city's 15-ton road rollers, but because the streets are generally dug out of slimy clay soil, which has a mean trick of caving in, so that special stability was the best means of guarding against disruption. Rigidity of the rails in relation to each other is also insured by the tie-rods, of which there are five to each length of 12 m., or, say 40-ft. rail. The radius of curves is 11 m. at La Jonction and 15 m., 18 m. and 20 m. in other parts of the city.

The entire new network of feeders is distributed by means of terra cotta conduit, which Mr. Field has had made specially in Switzerland for his work. It starts out from the city power plant at Coulouvreniere, from which current is taken under conditions that will be touched upon later. The unit of conduit is a two-duct piece, 70 cm (29½ ins.) in length, each duct having a 2½-in. bore. These pieces are laid edge to edge and bound with tar paper, as shown in one of the illustrations, and they are then grouted 10 cm (4 ins.) on all sides, making a solid, impermeable, yet easily accessible, system. In some places, as in the main thoroughfare, the Rue du Rhone, the conduit is under the track. The number of ducts varies from place to place, according to the requirements, being twenty in the section across from the power house to the Plaine de Plainpalais, and twelve, eight, six, four, etc., in other parts of the city. The system is reached by means of one hundred manholes, all of good size, the largest near the power house, central for the whole system, being 10 ft. cube. The cables for the work have been furnished by the Société D'Exploitation des Cables Electriques (Systéme Berthoud, Borel & Cie), Cortaillod, Switzerland. From the power plant to the big manhole, each way out, there are three cables on each side of 700,000 circ. mils each, and then smaller cables lead off for each line, according to the demand. To start up the first cars, some 12 km of 500,000 circ. mil cable had been drawn in at the time these notes were made, in the early part of the summer. In addition

TERMINUS OF MT. SALEVE RACK RAIL ELECTRIC RAILROAD, GENEVA—MT. BLANC IN DISTANCE

to this there is a four-circuit telephone cable cut at each manhole, so that from those points communication can be had immediately with the power plant, office or car house.

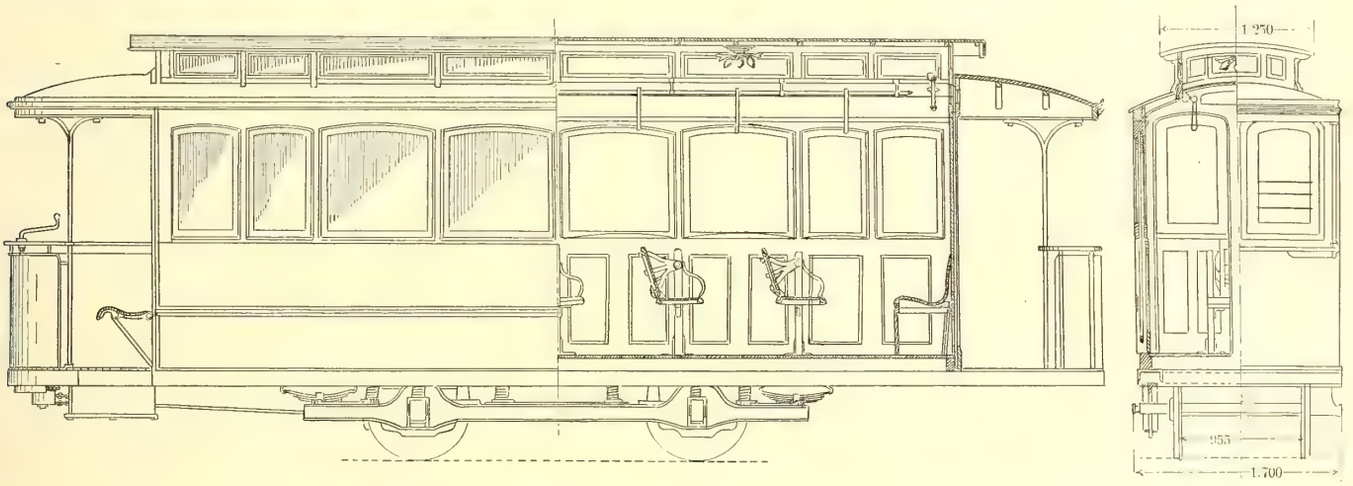
The line construction may be said to follow American practise in general so far as relates to the pole line, etc., and much of the material has been supplied by Robert W. Blackwell & Company, Ltd., of London; while some excellent insulating pieces used are from the Société Française d'Ambroine, of Paris, and other material has been supplied by the Duisburg Iron Works, of Duisburg, near Cologne. About 13 km (8 miles) of pole line have been put up. Some of the poles are made with side web, from two flat slabs of iron, drawn and welded at the same time; with 20 ft. in the single lower piece and 10 ft. in the single upper piece. In securing heavy corner poles to sustain unusual strain, Mr. Field, with characteristic ingenuity, has resorted to the device of taking a pole of large diameter, filling up the hollow space by dropping old rail down into it and then cementing the whole mass inside. The result is enormous stability.



MAP OF GENEVA, SHOWING THE TRAMWAY SYSTEM

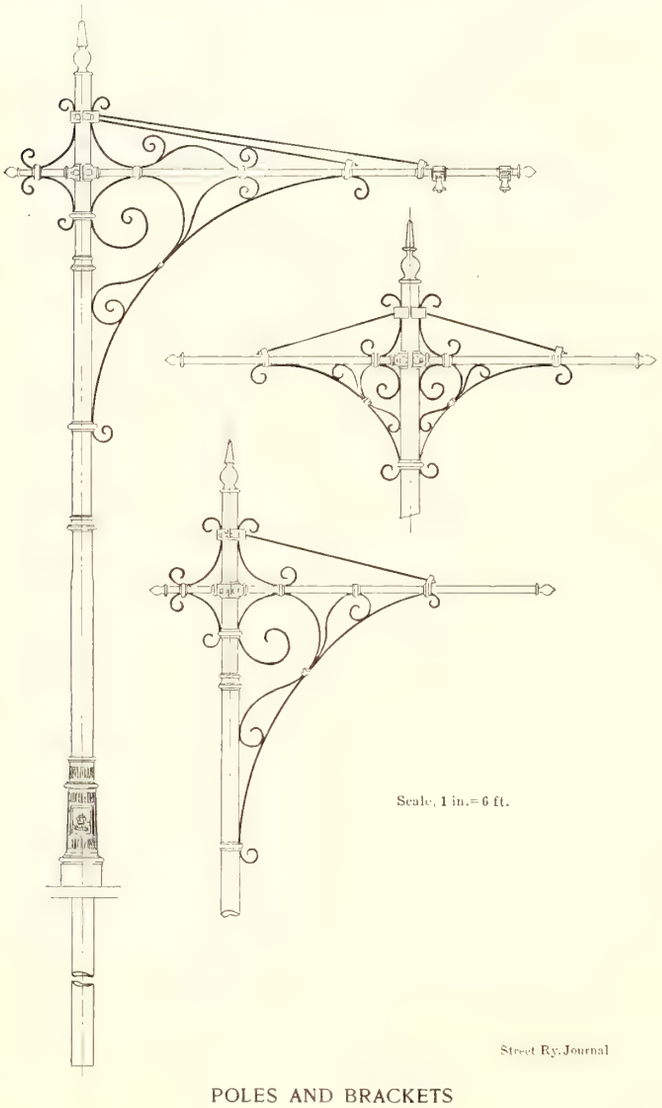
In addition to the pole line, the company has up about 15 km (9½ miles) of line fastened on buildings by rosettes, a great many of the streets being too narrow to admit poles. One of our views shows a construction gang putting up line of this type last May. The least distance permitted from wire to rail is 6 m. In the Place du Rhone there is a very interesting piece of work of this character, it being a very open space, with a cross street on one side, coming in at right angles. One long span across is 80 m. (244 ft.) at a height of 7 m. (21.3 ft.), and across the street is a parallel span of 50 m. (152 ft.) length. The span wires are composed of fourteen steel wires stranded, each 2 mm in diameter. The unusually heavy construction here was rendered necessary by the fact that a double trolley wire had to be supported for the turn-out. The end plates for this style of construction are heavy, and their pins, made of inch rod corrugated, are driven in about 8 ins.

In making his cable joints on the construction work, Mr. Field has adopted a plan which seems to be both new and meritorious. The cable to be jointed is first scarfed at an angle of 45 degs. The cut-bare ends are left separate about 1/32 in. apart and clamped in a bullet mold in which is cast very hot nearly pure tin solder. This



PROPOSED NARROW GAGE CAR, GENEVA

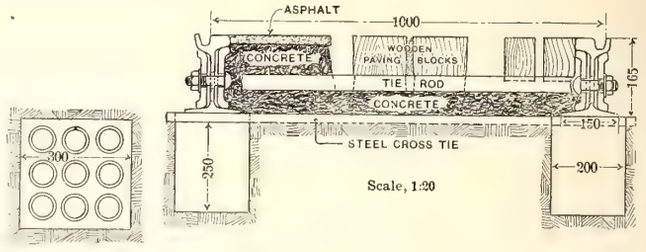
at once solders the ends of all the wires together and also the abutting ends of the cable, surrounding the whole core with an enlarged ferrule of the solder and giving the core a conductivity which slightly exceeds the theoretical. The joint thus made is then served and a sleeve of lead pipe is slipped over it. The ends of the sleeve are connected to the cable pipe by means of a cast joint made of very fusible solder. An air pump is then applied to the joint and the air exhausted until quite a high vacuum is obtained, thus testing the integrity of the envelope with the soldered ends. If when this vacuum has been obtained the joint tests out to have perfect insulation, a pot of hot



POLES AND BRACKETS

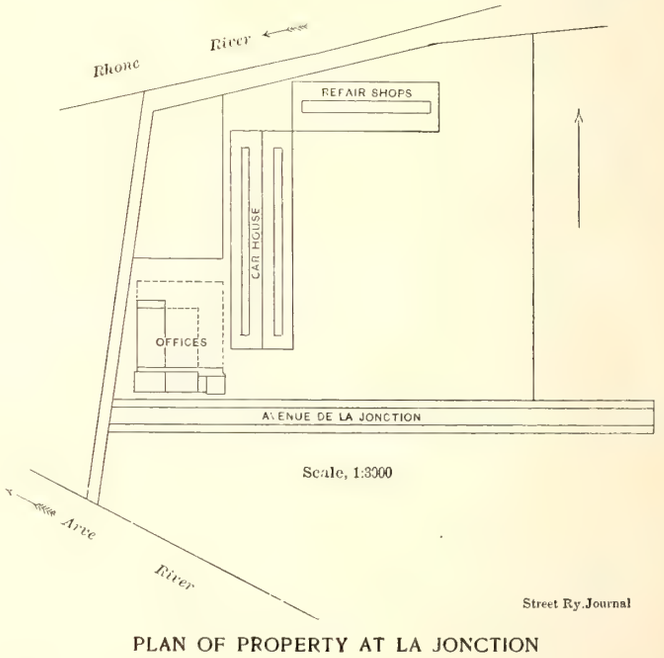
melted resinous composition is applied by a pipe leading into the joint, the opening of said pipe having been previously stopped with a wax plug. The hot compound melts the plug and the vacuum does the rest. The result of the process, Mr. Field says, is a joint of higher insulation than the normal cable itself.

The Compagnie Genevoise is relieved of all necessity of generating its own current, the city having, as is well known, developed the water power of the lake and river at its own expense and having set up a virtual monopoly of the supply, which it has been extending for some years past. The earliest plants are on the Rhone within the city itself, as in the case of the Thury plant, installed for the Tramways Suisses, as described in these pages three years ago. But the city, in 1896, having exhausted these nearby facilities, went further down the Rhone 3 miles or 4 miles to Chevres, where it established a fine Œrlikon plant for long-distance transmission to the Coulouvreniere power and pumping house, which is situated on the Rhone just above La Jonction and the property of the Compagnie Genevoise. A view is here shown of the present enlarged Chevres plant, for which we are indebted to Brown, Boveri & Company, of Baden, Switzerland, whose two-phase ma-



SECTION OF TRACK CONSTRUCTION

chines, supplied more recently, are seen in the picture. These machines have each a capacity of 1200 hp and furnish two-phase current at a frequency of forty-five periods per second at a potential of either 5500 volts or 2750 volts, at will. They are of the umbrella, vertical-shaft type, with fixed armature and revolving field, having forty-six poles carried by the cone-shaped magnet wheel. Above the machines is seen the large white marble switchboard of thirty panels and about 65 ft. in length, in the center being the three panels reserved for the service to the city, the tramways and the transformers at 2500 volts. This new



PLAN OF PROPERTY AT LA JONCTION

board was also put in by Brown, Boveri & Company, with their machines, to permit an easy manipulation of all the various units and types comprised in the plant. The current, delivered by underground cable at Coulouvreniere for the street railway work, is received at present by a 600-kw rotary on the same shaft as the generator, which in turn delivers direct current to the system at 560 volts. The contract with the city is at the rate of 12 cm, or 2.3 cents American, per kw-hour for all current up to 1,800,000 kw-hours per annum, and above that, 9 centimes, or 1.7 cents, for all current consumed. The current is delivered through meter, is available night and day, and the company's employees have access to the apparatus. The city concedes, however, to the Compagnie Genevoise the right to generate its own power, if it wishes to do so, after the quantity named above has been reached, and Mr. Field, who has had considerable experience in these matters, believes it would be worth while to do that rather than pay such

rates. It is to be hoped and expected, however, that with the opportunity to draw from such a fine plant as that at Chevres, where every increase of output must tend to reduce the cost of production materially, a basis of agreement on fair terms can readily be found. It will be understood that the cost to the company begins only at the moment when it receives the current on its own network. Examples of this plan of current supply are probably quite rare.

The Compagnie Genevoise is allowed five years for its work of construction and equipment, and the charter runs sixty-five years. It is permitted to collect a fare of 10 centimes, or 2 cents American, for the first kilometer, which is at the rate of nearly 3 cents a mile, and 5 centimes, or 1 cent American, for each succeeding kilometer. City

ENTRANCE TO EAUX VIVES

servants on duty are allowed to travel free, and there are school children rates, which do not seem to be used much. There are no transfers, and the tariff is considered such as will yield the company a fair return on its large investment.

Naturally, the American management of the road has been very much alive to the creation of new travel, and especially to the development of pleasure parks which shall induce the people to seek rational and healthful amusements by patronizing the lines. Among the parks reached by the lines are the Ariana and Mon Repos, but the most striking is that known as the Parc des Eaux Vives, at the end of No. 2 , or Hermance, line, on which were taken the views of track construction shown in this article. This beautiful resort was the homestead of Louis Favre, the famous engineer of the great St. Gotthard Tunnel, whose construction ruined him, so that the property has passed out of the hands of his family and has become one of the most picturesque resorts imaginable, with its springs, chalets, alpine groves, theater, dancing hall, etc. The possibilities of traffic in this direction may be inferred from the fact that last summer, when proper car facilities were lacking, over 250,000 people went out to this place in rough wagons. From this Hermance side of the lake a line of ferry boats run to the other side, or Versoix, where many of the wealthy have their homes, and out in which direction the Compagnie is also pushing its lines along the Swiss shore of the lake, with its memories of Voltaire at Ferney, the Napoleons at Prangins, and Madame de Stael, at Coppet. In the mere tourist travel to such places the company has a rich lode to work, for Geneva is one of the most frequented spots in all Europe. Moreover, the mountains around the city offer excellent opportunities for pleasure travel development, if made cheaper, as exemplified by the rack rail up Mont Saleve, from whose terminal chalet, at a height of some 4000 ft. above sea level, a magnificent view is obtained, not only of Mont Blanc and the Dent du Midi, but the valleys of the Arve and the Rhone, the shores of Lake Leman and the distant crests of the Jura Alps. All this region is practically covered by the present and prospective system of the Compagnie Genevoise, and it may be doubted whether there is a better territory to be found for a system wisely and liberally administered.

There are other points of interest in the construction and operation of the road that might well be touched upon, but these must await the completion as a whole of the work, whose first stages were brought to a close in the past month of July. The executive of the system consists of S. D. Field, ingenieur directeur, and A. Kundig, chief of staff, to both of whom we are under deep obligations for courtesies extended. With them are associated F. Landolt, assistant to the chief of staff, and L. Delphin, H. Weber, J. R. Selfridge and E. Laval. It will also interest many of his former friends in America to know that young Robert McCulloch, of St. Louis, has also been associated with Mr. Field in work centering at Geneva, work of which, however, this is not yet the time or place to speak.

Filling Gravel Cars

The accompanying engraving shows an ingenious method of loading gravel at the pits, employed on the Indianapolis & Greenfield Railway, now building. The method was suggested by Mr. McMath, civil engineer of the road, with the result that the cost of loading the gravel car was only about one-quarter of that when the car was loaded with shovels. As will be noted, the means em-

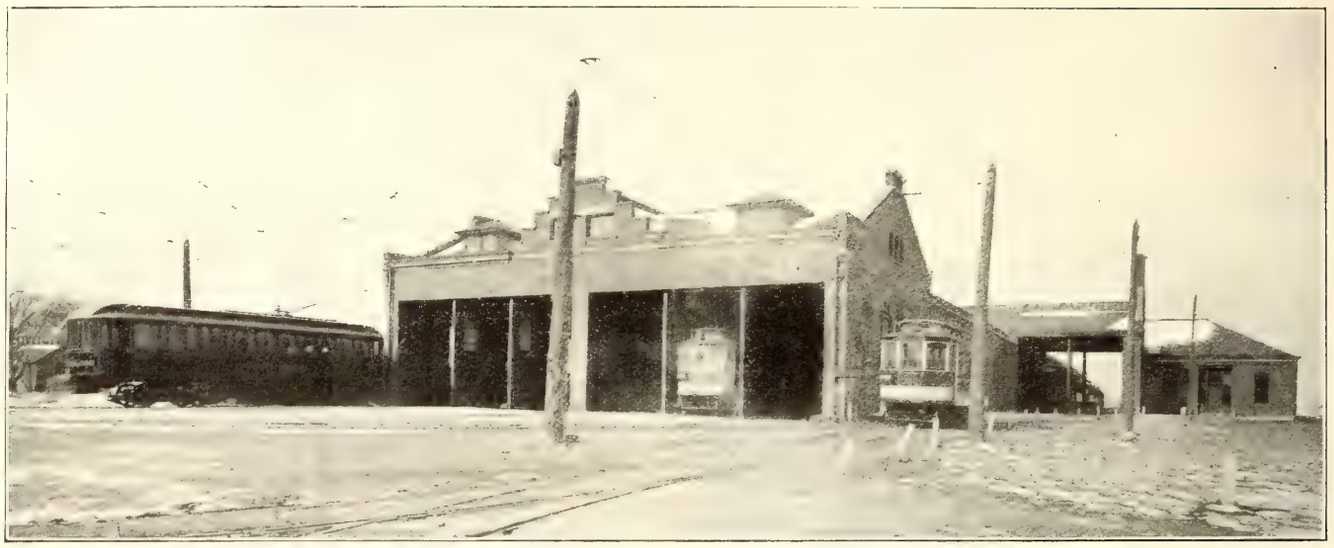
FILLING GRAVEL CARS

ployed are a temporary bridge, which can be readily removed and which is placed over temporary trucks. The road scrapers bring up the gravel and drop it through a hole in the bridge. Each team handles about 50 cu. yds. per day. The scheme, while not new, is an excellent one, but is doubtless unknown to many.

The Street Railway Journal is indebted to the consulting engineers of the Indianapolis & Greenfield Railway Company, E. P. Roberts & Company, of Cleveland, for the photograph from which the engraving was made.

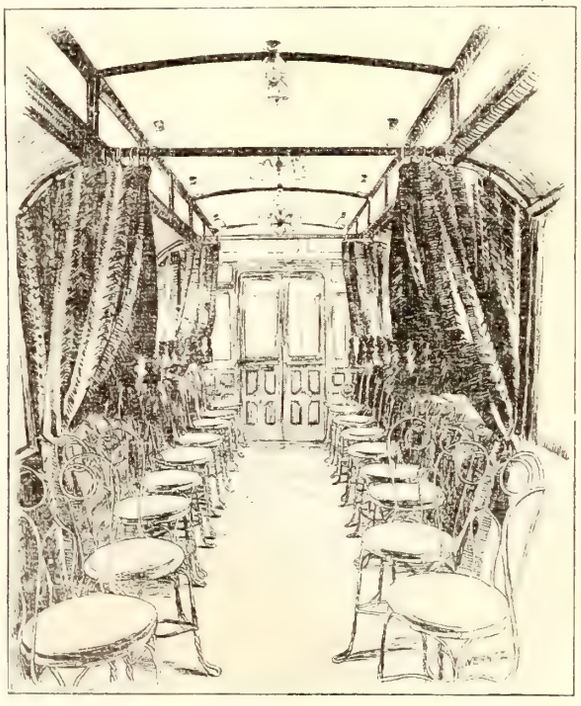
Funeral Cars on American Street Railways

Two years ago a description was published in these columns of street cars used for funeral purposes in the city of Mexico. Several cities in this country have now taken up the idea and the funeral trolley car may be seen in Chicago, Cleveland and St. Louis. The system has not as yet been adopted in any other cities in the United States, so far as is known, but the comfort and convenience which it gives will probably extend its use.



CAR HOUSE OF CLEVELAND ELECTRIC RAILWAY, SHOWING FUNERAL CAR AT LEFT

The electric funeral cars now in commission have in nearly every case been made in the railway company's own shops by changing over one of the regular cars to suit it for the service required. The cars selected have, in general, been of the eight-wheel type, and have been repainted in some sombre hue so as to combine solidity, ease of motion and elegance of appearance. Some special arrangement has had to be made for admitting the casket, but with this exception little alteration in the car body is necessary.



INTERIOR OF CHICAGO ELECTRIC TRACTION FUNERAL CAR

The car shown on the tracks at the left of the first illustration on this page was built in the summer of 1899 by the Cleveland Electric Railway Company for the joint use of that company, the Cleveland City Railway nd the interurban lines running from Cleveland to Akron, Painesville, Lorain, Oberlin, etc. It is 28 ft. long and 8 ft. wide, is painted an ebony black with simple gold trimmings and has the windows draped with green tapestry and yellow silk. The interior is divided into two compartments. The one in front, intended to receive the casket, has drop-down doors on each side and is draped throughout in heavy broadcloth. There is accommodation for four caskets besides shelves for receiving the floral offerings. Sunken rubber rollers are placed in the floor to facilitate the entrance and removal of the caskets. The rear compartment contains seating capacity for twenty-eight persons. The seats, for greater durability, cleanliness and healthfulness, are of split rattan.

Instead of a fixed partition the car used in Chicago has portieres which may be drawn or not as desired. The remains are admitted through doors in the end of the vestibules and the casket is placed on pedestals in the ordinary manner in any part of the car the mourners wish. The lines of the Chicago Electric Traction Company, which operates this car, reach the cemeteries of Oakwoods, Mt. Olivet, Mt. Hope and Greenwood, and in the spring and fall of the year it averages a trip a day.

A funeral car has lately been started in St. Louis which sets aside the middle of three compartments as the resting place of the casket. Entrance is effected by a movable panel in the side of the car which rolls upward while a trestle containing rollers on the bottom may be pulled outward to receive it from the pallbearers. It is intended that the immediate family will occupy one of the end compartments and the friends of the deceased the other. The car, which is the first of six to be installed on this road, is handsomely finished on the outside in chocolate brown and has the interior upholstered in appropriate colors with black velvet curtains and Brussels carpets.

In operation, the cars are side-tracked at the nearest convenient point during the funeral service. In Cleveland thirty-six stations have been set aside for this purpose. At the conclusion of the service the casket is carried from the church or house by the pallbearers and placed in its position. Arriving at the cemetery the casket is again taken up by the pallbearers and either carried to the grave or else placed on a hand carriage or hearse which is in attendance. While in use the funeral car has the right of way, and as it waits on a switch, both at the church and cemetery, the funeral party proceeds throughout with no delays.

Testing and Repairing Methods of the North Jersey Street Railway Company

The North Jersey Street Railway Company, which operates all of the lines in Jersey City, Newark, Paterson and in many of the neighboring towns and country, has in service over 231 miles of track and about 750 cars. The extent of its system has compelled the company to give especial attention to the care and repair of its rolling stock. Most of this work is carried on at the Plank Road repair shop of the company in Newark, although many of the car houses of the company are necessarily equipped with facilities for making slight repairs.

One interesting feature of the Plank Road repair shop is that nearly all work done is paid for on the piece-work system. This method was introduced into these shops four or five years ago and has proved most satisfactory to both men and company. The former find that they earn more than formerly, while the total cost of repairs has been reduced to the company.

The first test illustrated is that to determine short circuits in railway armatures, and employs the well-known alternating-current method, the chief novelty lying in the fact that the alternating field is portable and is taken to the armature, instead of having the apparatus stationary and

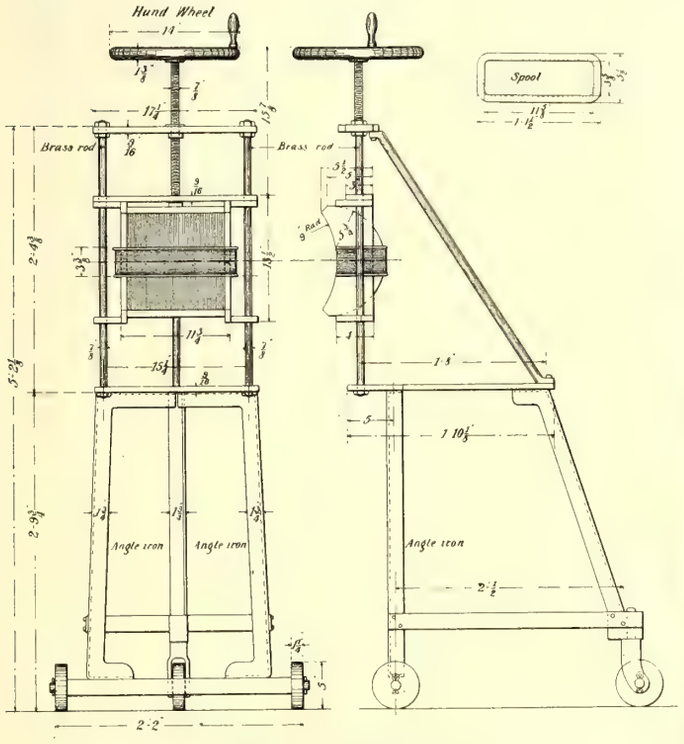


FIG. 1.—ALTERNATING CURRENT COIL FOR TESTING MOTOR ARMATURES

moving the armatures to it. The great advantage of this is that the testing rack can be moved from one lathe or winding bench to another, or wherever an armature is being repaired, and the armature coils can then be tested with a minimum amount of trouble.

The alternating field rack employed was designed by the master mechanic of the North Jersey Street Railway Company, H. H. Adams, and is so easily constructed that working drawings are given in Fig. 1, which shows a framework made of angle iron mounted on three rollers. The magnet core is made of laminated iron about 1/32 in. thick, and of the shape and size shown in Fig. 1. This device is adapted to test G. E. 800's, 1000's, 1200's and 57's, and Westinghouse No. 3's and No. 12's. The magnetizing coil is made as shown and wound with 1210 turns of No. 13 B. & S. double-covered cotton wire. The curved face of the pole piece is adjusted by a hand-wheel and screw, so that it can be shoved up against the armature without removing the latter from the winding bench.

The body of the armature completes the magnetic circuit of the alternating current magnet; the armature is then rotated by hand in this field. If any two windings are

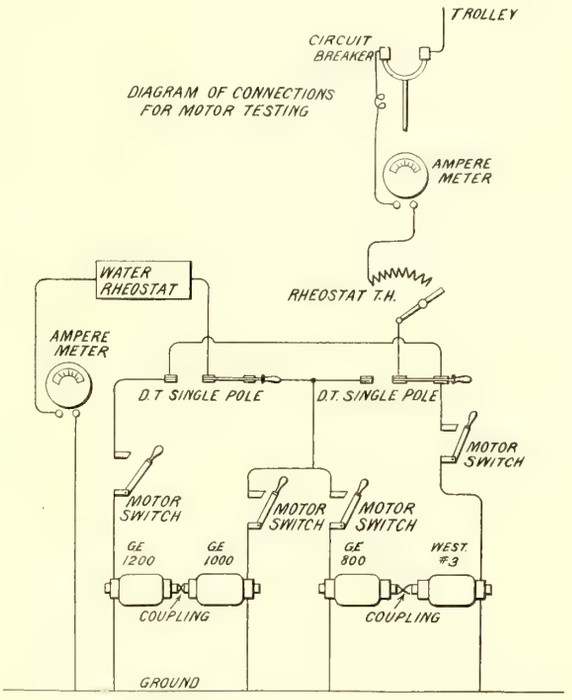

FIG. 3.—DIAGRAM OF CONNECTIONS FOR TESTING TWO ARMATURES

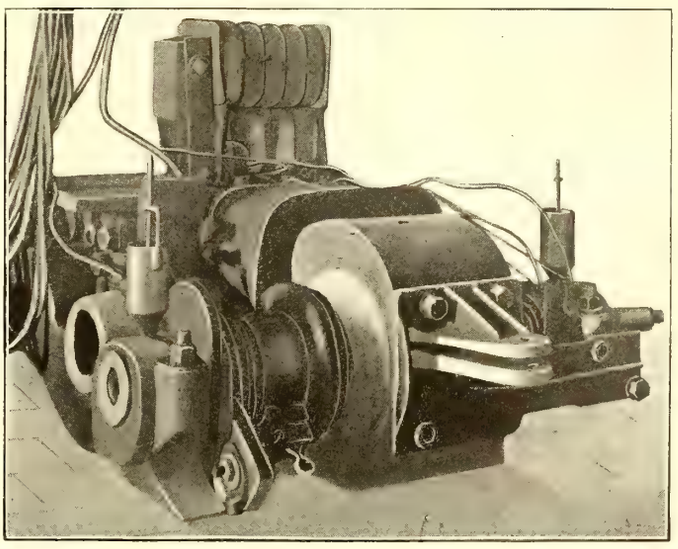

FIG. 2.—S. R. G. 30 MOTOR USED AS ROTARY CONVERTER

short-circuited and are within the influence of the varying magnetism, a local induction circuit is created which causes a vibrating magnetic flux in the teeth of the armature included in the short circuit. This is discovered by passing a thin strip of iron around the armature, which, when over a short-circuited coil, will vibrate in unison with the alternating current supplied to the magnet. This vibration is due to a local short circuit formed by the connection of two adjacent coils. The magnetism, which is induced by the local flow of current in the short-circuited coils, produces a magnetizing effect differing in its time from the magnetism of the adjacent teeth. This, as stated, causes a vibration of the iron strip when over the tooth lying between the short-circuited coils. There will be two such points in the armature at a quarter from each other

when two adjacent coils are short-circuited; but four coils are affected when the short is between commutator bars, which are connected to these two coils, and the four magnetizing areas will be found at equidistant points around the armature body.

The current for this testing device is obtained from an S. R. G. 30, Fig. 2, having two slip-rings secured to and insulated from the shaft and connected to the windings of the armature. These rings are located one-quarter of the circumference of the armature from each other in a two-pole motor. This motor is wound with a shunt field of fine wire, and has a speed of 1400 r. p. m.; this gives a good frequency to detect these crosses.

The armature room is wired for this current over the winding benches, and flexible cords with attaching sockets are located at points convenient for connecting to the testing device. When located at any winding bench an armature can be tested by this method in less than one minute.

The armature is then given a running test. There are two pairs of standard railway motor fields fixed to the floor, but turned upside down, so that it is only necessary to raise the cover of each to introduce the armature to be tested into the field, the brushes being out of the way. Four different fields are provided for the four types of motors used on the road. The armature to be tested is then directly connected with another armature in the other field of the pair already mentioned, one machine running as motor and the other as generator. The G. E. 1200 and 1000 motors are tested against each other and the G. E. 800 and Westinghouse No. 3. A chuck coupling is provided, which couples both pinions with set screws that enter between the teeth, and each pair of frames is set so that the armature shafts are aligned. Fig. 3 gives the diagram of connections for the testing of these motors. By the way the switches are thrown, the Westinghouse No. 3 is ready to run as a motor and the G. E. 800 will run as a dynamo, the water rheostat being adjusted to give the proper load for the test. The armatures are run this way for five minutes and then, by throwing over both double-throw switches, the G. E. 800 becomes the motor and the Westinghouse No. 3 the dynamo. The armatures are raised and lowered into the fields by an air hoist, which is on an overhead track, so that they can be moved easily from one end of the shops to the other.

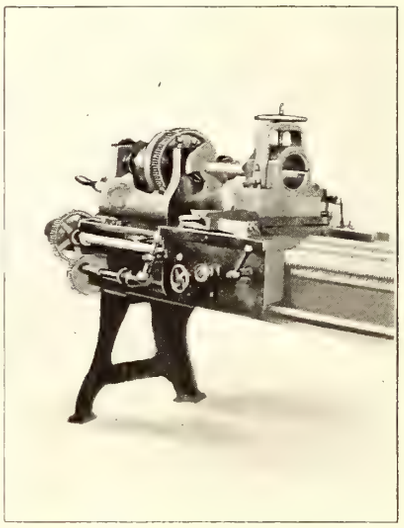

FIG. 4.—BORING ARMATURE SHELLS

FIG. 5.—CHIPPING OIL WAYS

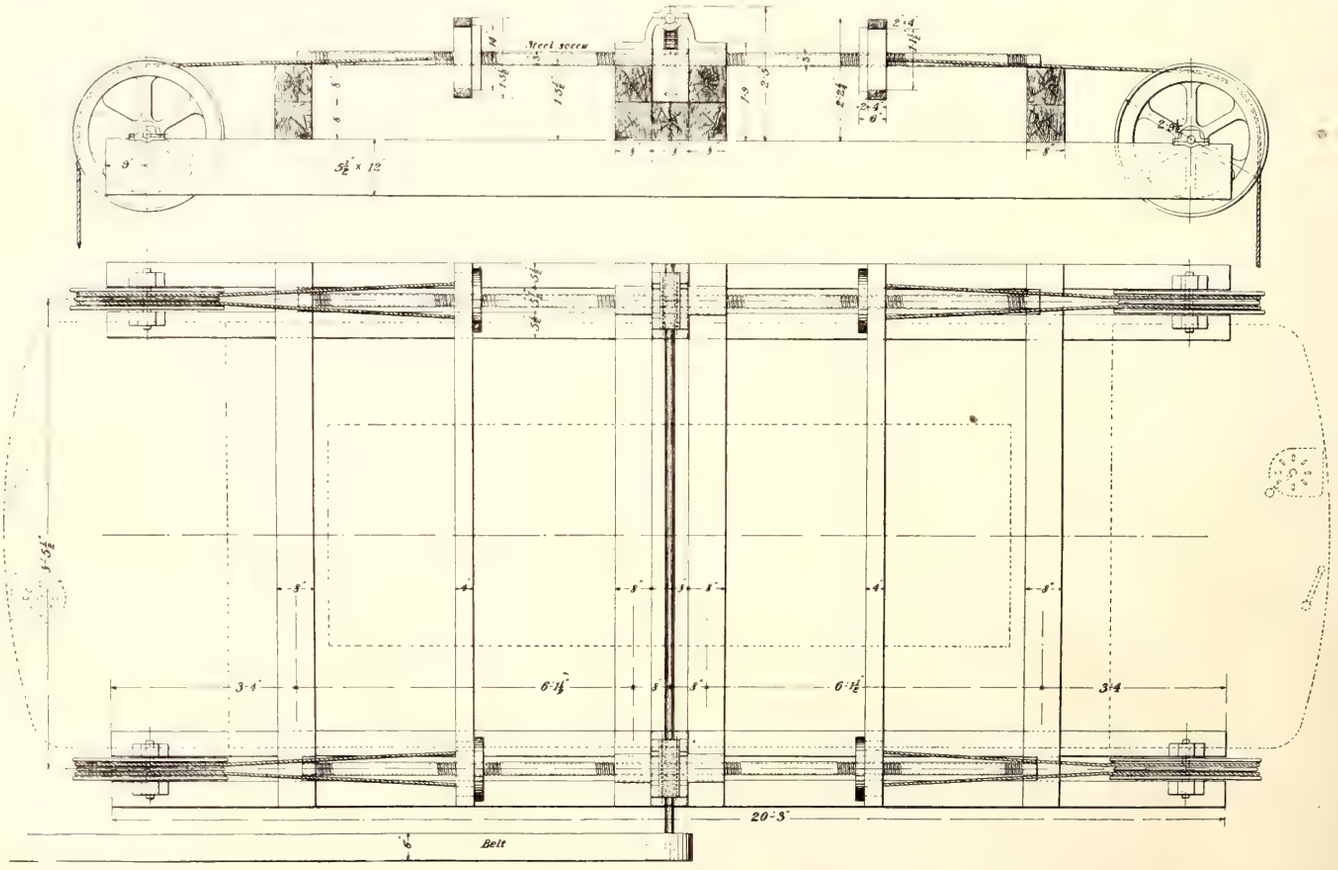

FIG. 6.—PLAN AND ELEVATION OF CAR HOIST

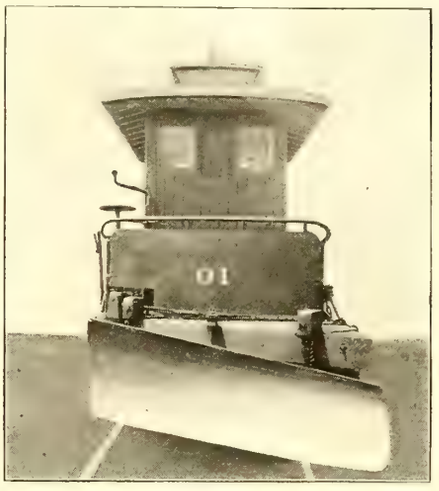
The method of boring out shells employed by the North Jersey Company is to mount a chuck, shown in Fig. 4, proper size chucking pieces being used for each style of shell, on the carriage of a lathe. The boring tool is fed into the shell and the babbit bored with one cut to size.

The oilways are cut by a pneumatic tool, as shown in Fig. 5. One man tends to both operations, cutting oil-ways while the boring tool is being automatically fed through the shell.



FIGS. 7 AND 8.—SNOW PLOW, NORTH JERSEY STREET RAILWAY CO.

The car-body hoist, as shown in Fig. 6, has been described in a previous issue of this paper, but the working dimensions are given, so that duplicates can be made more easily, if desired. This hoist consists of an old railway motor belted to a shaft carrying a worm, the gear of which meshes into the worm and turns a shaft provided with a right and left-hand screw thread. To the nuts which run on this thread are attached the hoisting cables, which pass over the sheaves at the four corners of the hoisting device, and drop to the floor below where the repair pits are located.

Two stringers are placed under the car body, and to these stringers the cables are attached. The motor is then started up and the car body raised out of the way of the truck. The hoist shown, Fig. 6, can raise with ease a double-truck body weighing 18,000 lbs.

The snow-plow which the North Jersey Street Railway Company employs and has designed is shown in Fig. 7 and Fig. 8. The front of the plow has a curved surface, which, instead of pushing the snow ahead of the plow, runs under the snow and rolls it over like the mould-board of an ordinary farmer's plow. The adjustment of this plow is parallel with the track and is effected by swinging the plow on two chains, both winding on a drum, to which is attached a gear, into which meshes a worm gear terminating in a staff and hand-wheel.

When in use, the plow is operated by two long radial arms secured to the car body, which resist the pressure of the snow, and the plow can be readily swung up and down by the chains. The side wings are raised and lowered by a lever hinged from a standard projecting below the platform. The width of the plowed way is regulated by a chain-guy attached to a locking lever as shown.

The track plow is a short V-shaped plow resting on the head of the rail. This clears special work and high joints by being supported on a spring, acting in the line of movement of the car. The North Jersey Street Railway Company reports such good results from the performance of this plow that the company is building a number of others.

The Milwaukee Carnival

The possibilities in the way of electrical decoration and illumination in street parades afforded by the overhead wires of a trolley road have been proved in several cities, particularly in New Orleans, and views of the floats used in the Mardi Gras processions in that city last winter were published in the STREET RAILWAY JOURNAL. The unlimited current available for lighting and power to propel the floats makes it possible to secure finer spectacular effects than would otherwise be possible. This was shown during the special carnival, held June 28 in Milwaukee, in which the trolley current was used for this purpose to a greater extent probably than ever before, and which was generally regarded as one of the most successful night pageants ever held on this continent.

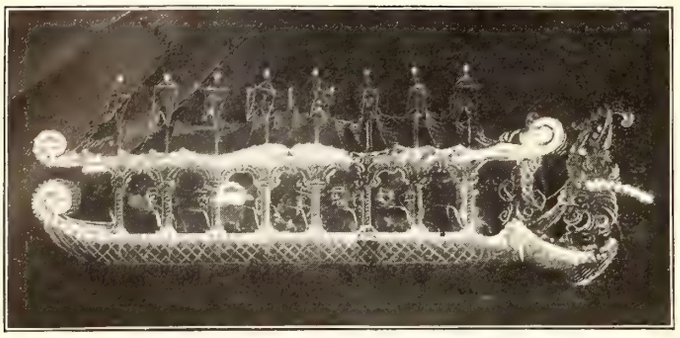
The parade consisted of twenty floats, placed on electric trucks, and lighted by 6000 lights of different colors. They consisted of a variety of subjects, presented without any aim at continuity of idea, but solely for their picturesque beauty and scope for fantastic display of form, color and effulgent light.

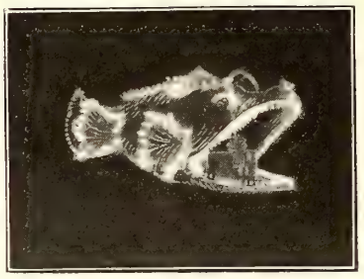
ILLUMINATED STREET, MILWAUKEE

The first float was a fac-simile of the battleship "Wisconsin," and, under the strong lights that focused on the spot, she seemed a real ship afloat on a white sea. Several musical chariots, decorated with swans' necks, whose heads extended far in advance of the charioteers, dispersed radiance and music at the same time. The float carrying

Rex was draped with foliage of tropical abundance. The king stood up in the midst of four columns, surrounded by hundreds of lights, which added an effect of royal splendor to his luxurious and majestic appearance.

A striking float was that in which the Goddess of Light stood on a sun bristling with golden rays, covered with electric lights, driving two prancing white horses. On the next float was a half godlike figure, poised on one foot, ready to fly from the banked clouds of Olympus on some world-wide errand.





VIEWS AT NIGHT OF TWO OF THE ILLUMINATED CARS

"Comus," the king of laughter, and "Jupiter," the king of gods and men, were two very attractive floats. A representation of Hades followed, which gave the public a realistic show of the unholy world, the head of Hades and his satellites having prominent positions on the car.

The largest figure in the parade, and the one that caused quite a sensation after the battleship "Wisconsin," was the whale, with one supposed to represent the prophet Jonah sitting in his wide-open jaws. This float was on a 50-ft. flat car, and was decorated with 900 lights, giving it such a glowing appearance that one could almost imagine that the sides were transparent and that by some hocus-pocus the figure in the jaws would pass down the throat and be seen after he had reached the bottom. A view of this is given.

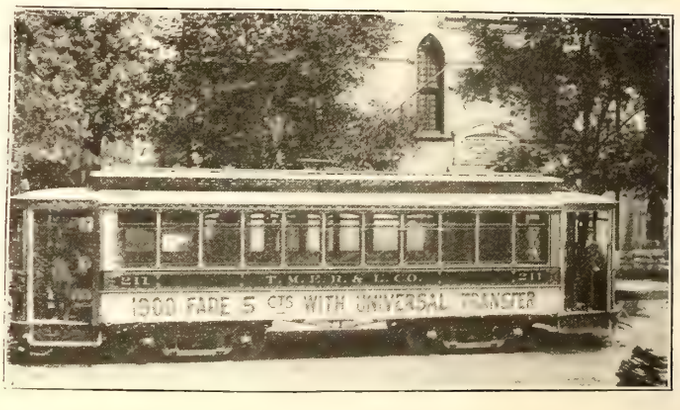
Another float was founded on the Mother Goose tale of "The Three Wise Men" of Gotham and their nautical experiences. The sea, with green and blue waves tossed mountain high, was there, and in the midst, emphasized by a corona of light that came from fifty lamps, was a bowl that carried the three immortal men.

Another float represented a dragon, with its writhing folds fitted in every joint with clusters of white lights.

Probably the most interesting of all the floats was the one that brought up the rear. It was symbolical, and represented the ideal Prince Carnival and his court. All races were represented in the motley group, not only Caucasian, Indian and Malay, but Negro, Chinese and Zulu as well. The Chinese representative was particularly admired by the crowds as the float passed, and he was pointed out derisively as a "Boxer."

The contract price for the making of the floats was $5,700, and the wiring, power and cars cost $1,800 more, making $7,500 in all.

One of the interesting features in the "funny parade" on Corso Day was the exhibit of the street railway company, which consisted of four cars, viz.: The first was an old car of the bus type, which was used on the Cream City lines in 1870. It bore a sign reading, "1870, fare 6 cents." The second was an old box-car, which had been used on the McGeogh lines in 1880. It bore a sign reading, "1880, fare 5 cents." The third was an old box-car, which had been used on Milwaukee Street Railway's lines in 1890. It bore a sign reading, "1890, fare 5 cents." The fourth was a standard double-truck, four-motor closed car, of the Milwaukee Electric Railway & Light Company, 1900. It bore a sign reading, "1900, fare 5 cents, with universal transfer." This was an object lesson, showing the great

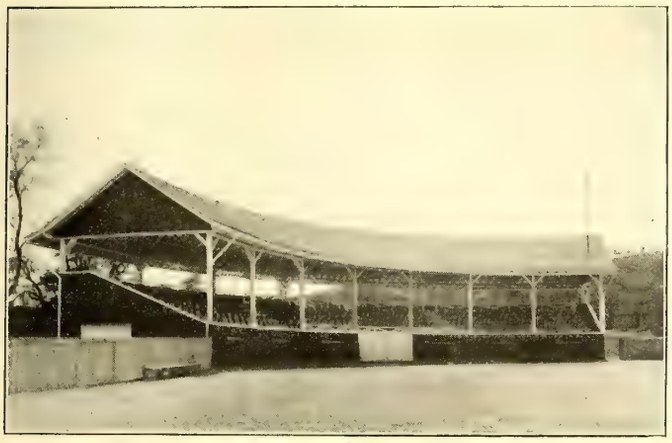


DAY EXHIBIT OF THE MILWAUKEE ELECTRIC RAILWAY AND LIGHT COMPANY

advance in street railway transportation facilities, which the thousands of spectators were not slow to appreciate.

Kennywood Park

In the monthly issue for April of the STREET RAILWAY JOURNAL a description and some views were published of the Monongahela Street Railway Company's Kennywood Park, near Pittsburgh. The views shown were of improvements made in 1899 when the park was first laid out. The success of the park during its first season was so great that the company decided to make extensive improvements this year, and the views shown in this issue are all of structures that have just been completed.



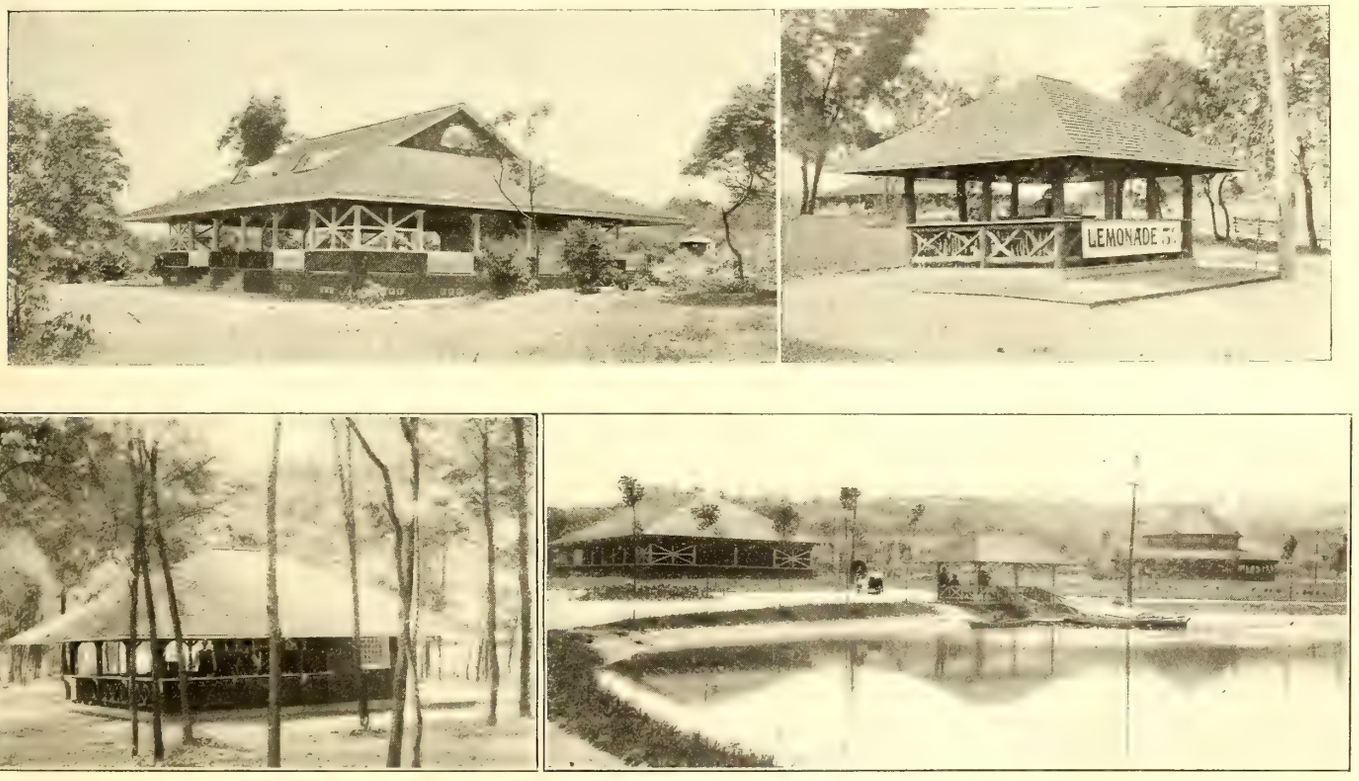
GRAND STAND

BAND SHELL

One of the principal attractions is the new band-stand, which has a stage 40 ft. wide and 40 ft. deep, with a proscenium arch 30 ft. high. There are six dressing-rooms, three on each side of the stage, for use when performances other than band concerts are given, it being the intention of the company to have minstrels, concert troupes, etc., during the present season. The stage is also provided with a plain white canvas curtain, as a protection from rain and for biograph pictures. The structure is well lighted, having over 500 incandescent lights.

Another new feature is the baseball ground, measuring 400 ft. x 400 ft. There is a grand stand having a seating capacity of 600, and two sets of "bleachers," each seating 700 persons, or a total seating capacity of 2000. The space under the grand stand is utilized by dressing-rooms for the players, a refreshment stand and storage room.

One feature of the park which was very popular last year was a private dining pavilion and kitchen, where picnic parties could have conveniences for eating their lunches, preparing hot coffee, etc. This pavilion was in such great demand that a second one was built this year, and is shown in one of the views.



TYPICAL BUILDINGS IN KENNYWOOD PARK

There have also been built several rustic refreshment stands, scattered around through the park, views of two of them being given.

The park was laid out and the construction superintended by Wilkins & Davison, civil engineers, Pittsburgh, and the improvements made this year and shown in the

TROLLEY STATION AT PARK

views were designed by and built under the supervision of Wm. Glyde Wilkins, C. E., successor to the above firm.

As will be seen from the views, the improvements are much more artistic in their design than is usual at street railway resorts, and, while they are artistic, their cost has not been great.

A Test of Incandescent Lamps for Street Railway Service

The Massachusetts Electric Companies, which own a large number of the street railway systems in eastern Massachusetts, have made unusually thorough and elaborate tests of incandescent lamps under railway conditions to determine the most desirable make for use in their cars. Twenty makes were tested, a barrel of each being bought on the open market. Ten lamps of each make were connected in two series of five each and supplied from a street-railway circuit with the usual commercial regulation. The five lamps in one series were given a life test, and whenever one burned out a lamp which had burned the same number of hours in the other series of the same make was put in its place, a new lamp being put in the second series. Each lamp in the life-test series was measured every twenty-four hours for candle power and watts. The work was carried on at the Hyde Park station and required no small amount of work, two men being constantly employed for the six weeks during which the test was continued. By night, when the street railway system was shut down, the 200 lamps under test were supplied by a special machine at constant voltage.

Great care was taken to obtain accurate standards, three standards being obtained from each of the three companies; one from each company was sent to the electrical laboratory of the Massachusetts Institute of Technology, where five more standards were prepared; secondary standards were then made from these five. The companies' specifications call for a 4-watt lamp giving an initial candle power between 15 and 17, and taking initially a power between 60 and 66 watts at 110 volts, no lamps to drop below 25 per cent of the initial candle power within 1000 hours.

Can Small Electric Railways be Operated at a Profit? I.

BY JAMES BLAKE CAHOON

The statistics given in the report of the New York Railroad Commissioners for 1899 are certainly deserving of the most careful study by the managers of small roads. When the electric railway was first introduced everybody took it for granted that under any condition in which a franchise for the operation of an electric road could be obtained, no particular thought need be taken as to whether or not it would be a paying proposition because it was assumed that it must be. This assumption was perfectly correct so far as the operation of an electric road in a large city is concerned, this class being money makers from the start, but to the surprise of nearly everyone electric railways in smaller cities as a rule are only just able to make their bond interest, or show a deficit.

There are ninety-four electric roads in operation in the State of New York; in the year 1899 forty-one of these showed an actual deficit, fourteen declared dividends ranging from 1 per cent to 12 per cent. Of those that declared dividends, four only were in the smaller cities, three being operated partly as interurban roads, and one declaring a dividend on its capital stock, although it had accounts payable largely in excess of the amount of the dividend and its surplus, the interurban part of the roads in smaller cities seeming to be the salvation of the whole.

We are then confronted with the condition, practically, that roads in other than the first and second-class cities, where electrically operated, are not at the present time a paying investment. In searching for a reason for this it is necessary to go back over the history of the equipment of electrical roads in the past ten years, and study cost of installation, methods of management and rates of fare, and see whether one or all of these were instrumental in bringing about the present condition. Naturally, in the beginning of the industry, equipments were crude and expensive. Many roads, in changing over from horses to electricity, placed the motor equipments on their old cars, and did nothing to their tracks other than to bond them and build an overhead line. First the cars went to pieces, then the tracks, and the equipments struggled along in varying conditions, all having finally to be replaced.

When the conversion was made the money for it was obtained, as a rule, by issuing bonds; then, when the tracks had to be rebuilt and new cars and new equipments ordered, new bonds had to be issued, so that for the ultimate equipment of the road, practically a double issue of bonds was made, the first issue being for experience so far as actual benefit was concerned. The result is that the roads which were converted from horse to electric are now confronted with interest charges on a double issue of bonds, which render the task of making the roads a paying investment very difficult, and one by one these roads have given up and gone through the process of reorganization and rehabilitation in an effort to place themselves on a paying basis.

The *Century Magazine* for June, 1900, contains an article in "Topics of the Time," headed "Public Peril in City Franchises," in which it states that "those who are watching current events must be aware of a remarkable activity on the part of those corporations engaged in the performance of public services in the cities in the direction of securing extension or confirmation of the privileges they are enjoying, and that franchises have been granted and renewed for almost no consideration," and further on it remarks that "these franchises are in almost all cases

enormously overcapitalized;" that "what they wish to do is to pay interest on two or three times as much capital as they have actually invested."

It is true that a street railway to-day could be built at much less expense, and with much less burden of bonded indebtedness than roads are at present carrying, but the bonded indebtedness of existing roads is an honest debt, contracted with the idea of, in the first place, giving the public adequate service, and secondly, meeting the constantly increasing requirements of the people for better service. Undoubtedly, the original promoters went into the project with the idea of making money for themselves; they built the road, placed the bonds and took as compensation stock which paid well for a sufficient time to enable them to unload largely on the local people, but as years went on the dividends became less and less, the stock depreciated in value to nothing almost, and the men who are holding these stocks to-day are men who put their money into them in good faith and are endeavoring under almost hopeless conditions to obtain a fair return for their investment.

If their franchise expires and they do not obtain another or a renewal of the old, the money they have invested is hopelessly lost. The *Century* speaks of overcapitalization, injecting water into the stock, etc., and thinks that franchises should be paid for, and it is conceded that they should be where the franchise is of value, but, so far as railways are concerned, such franchises are of value only in the large cities, and in order that justice be done, distinction must be made between street railways of small cities and those of larger cities. What they may assert with perfect truth as regards railways in large cities would be anything but true, and a rank injustice to railways in small cities.

In general, the roads of which we speak were laid out somewhat crudely, but they may be roughly divided into four classes: First, the city having its business concentrated largely on one main thoroughfare, covering a territory about one-half mile in length; surrounding and reaching out from this lie the residence districts, and the road found in this class of city usually consists of three to five short branches running out into the residence districts and centering in the business district. In the more pretentious cities efforts have been made to attract travel to the road by the establishment of a summer theater and park on an extension of one of these radial arms, and this may be classed as the second division. The third division is where the town is divided by a river, and has the main business thoroughfare along the river, the town extending in a general way along both banks without running very far back at any one point. In this class of town the railway usually zigzags from one end of the town to the other, and if the settlement be about equal on both banks of the river, effort is made to reach the people on one side by means of branches or a loop system shooting off from the main line. The fourth class is formed from a combination of the first and third classes, with an interurban branch extending to a small town from 5 miles to 15 miles distant. A distinct characteristic that may be noted of all this class of roads that have been in operation for some years is that their superintendents and managers, who have striven hard to make the roads pay in the face of an utter indifference on the part of the public toward helping them, have become imbued with the idea that, even though they practise the most rigid economy, they can just barely scrape together enough to make both ends meet.

They have become, as it were, hardened to the work and more or less blind to existing conditions, with the result that the property is gradually running down hill without their knowing it, and people become more and more indifferent to riding on the cars. Another characteristic is of the people of the towns themselves—a great majority is made up of those whose income is not great and to whom a nickel seems large. In the large cities, where the distances are great, the people naturally have to ride to and from their work; in the smaller towns this is not so. Usually in fifteen minutes the mechanic can walk from his house to his place of work, and the same is true of the great majority of people. The result is that rather than spend 10 cents a day to ride to his work in the morning and back at night, he will start ten or fifteen minutes earlier and walk the distance, hence the proportion of passengers riding in the smaller cities is much smaller than in the large cities.

For instance, if we were to compare the city of New York and one of the small inland cities of the State, we would find the number of passengers carried per car-mile to be three to one in favor of the large city, while, by rigid economy, the operating cost per car-mile on the smaller road is less even than on that of the big system; yet an operating expense of less than 10 cents a mile on the small road may mean that their operating expenses are 90 per cent of their gross receipts, while on the large road the same cost of operation per car-mile would probably mean not over 45 per cent of the operating expenses to gross receipts. The small road would not pay; the large road would pay the interest on its bonded indebtedness and a handsome return on a proportionate amount of stock based on water.

In the large cities the people must and will ride; in the small cities the people will not ride unless they either have to for some particular reason, or are willing to give up their nickel for considerably more than its value in pleasure, and the problem presented to the street railway manager is how to get this class of people to ride so that he can make his road pay. In general, the answer is that, taking into consideration all local conditions, he must contrive in some way to convince the people of the small town that he is not only giving them the worth of their nickel, but several times more than that, either in the way of very quick transit to and from their business, or in the way of amusements and pleasure of much more than the value of the nickel.

The nickel has become in a measure accepted as the general rate of fare for street railways, but local conditions may be such that, in order to get people to ride, it may prove the salvation of the road to lower the price; as, for instance, take in the first class of towns mentioned, where lines branch from a common center and no one of the branches is more than about a mile long. In a town like this the great majority of people would walk rather than pay 5 cents to ride a short distance, and a road charging 5-cent fares would have uphill work, but it might be so arranged that very cheap rates of fare could be given—say forty tickets for $1, with the understanding that those tickets are good for a ride on any one of the branches to or from the center of the town. If a passenger wants to go beyond the center of the town, then he pays for another ticket, and in case there was a park situated at one end of one of the branches, coupon tickets could be provided so that everybody riding to the park would have to pay 5 cents each way. Where passengers got on and did not have tickets, the cash rate of fare could be made 3 cents.

Suppose, under these conditions, the road just barely paid expenses with 5-cent fares, and by the reduction of these you could get three to four times as many people to ride, it will be seen that the road would naturally become

a paying proposition. Another method applicable to roads that zigzag through a town is the introduction of low rates of fare similar to the above outline, that is, forty tickets for $1, to be used during working hours. This has often proved the salvation of a road of that class.

On the roads of the fourth class, having an interurban connection, where the ordinary fare is 10 or 15 cents between the towns, make a commutation ticket, good for people going between the towns for business or work daily, on the basis of 60 per cent of the regular rate of fare, and on pleasant days give excursion rates in the afternoon and evening in the summer time, or when there is a skating carnival or anything of that nature gotten up in the winter time, at half rates. Then, instead of the cars running nearly empty during these hours, they will be well patronized and the receipts of the road materially increased without adding much to the operating expenses.

Naturally following this comes consideration of what it is necessary to have in the way of car equipments. It is absolutely necessary that these small roads be operated with a minimum amount of car equipment, and the first thing to be settled is the type of car which is best suited to work under all conditions in both winter and summer, as this class of roads cannot afford to maintain a double equipment of cars. Meeting this requirement as well as anything at the present time is a car of about 26 ft. length of car body, with double trucks, center aisle and cross seats of cane bottoms, vestibule ends, window sills cut down low, and the windows preferably double sash, so that they can be dropped down to make the car to all intents and purposes an open car in pleasant weather. Several combination cars have been exhibited—some with panels which can be taken out, and some with panels which slide up on the roof. These are now on trial and may prove a satisfactory solution of the problem, but their expense and construction are against their being adopted by small roads.

If we take, for instance, a road operating ten cars gen erally, and it has a park on one of its lines, in the summer time it may become necessary to operate twenty-five or thirty cars to handle the crowds during rush hours or on circus days or Fourth of July. A ten-car road should have as its equipment, where it has a park, fifteen motor cars of the type mentioned above, and as many trail cars. Where no park is in existence and it is only necessary to operate short lines, trail cars are not necessary, but the same number of motor cars should be had, for reasons which will appear later under method of inspection. Interurban roads would require two-thirds as many trail cars as motor cars.

The motor equipment where there are any grades should preferably consist of two 50-hp motors; 25-hp motor equipments, although they cost less at the beginning, are more expensive in the end, on account of costing more to maintain, and not being capable of satisfactorily handling two or three trail cars, heavily loaded, as may be often necessary. Speed is especially desirable in small towns, and usually these cities do not limit the speed as closely as in the larger towns, and, as a rule, cars should be operated at as high a rate of speed as is consistent with safety, slowing down on the busy thoroughfares, and the point of rapid transit should be strongly emphasized to induce people to ride. The heavy equipments mentioned serve admirably to the furtherance of this purpose, having sufficient reserve power to maintain time schedules with two trailers added.

Much has been written and more said, pro and con, in regard to the rate of speed at which to operate cars than on any other subject. I believe every writer who has given the matter serious consideration has tried to solve the problem by deducing rules governing the operation of electric roads in general. As a matter of fact, every road has got to be treated in a more or less different way, for roads are very much like human beings—they may have a general type of sickness and the same remedy may be applicable to all cases, but each requires supplementing with other remedies peculiar to the patient considered. Just so with regard to speed—one road may find it decidedly advantageous to operate at a very high rate of speed, while another, on account of certain local conditions, may find it more profitable to operate at a moderate rate of speed.

I remember one case in particular where a road zigzagged all over the town, and crossed and recrossed the steam railroad track several times in the course of its route. The cars were operated on fifteen-minute headway, but given a very slow time card. In talking the matter over with the manager, seeking the reason for this, I found that while he wanted, and his patrons almost imperatively demanded a high rate of speed, it was practically impossible for him to give it, the town being situated on the main line of one of the large steam railroads with an enormous freight traffic; long freight trains were running through the town continuously, so that the same motor car would be stopped at the first crossing to wait from two to seven minutes for a freight train to pass, and then get up to the second crossing and strike the same train again. If he operated at a high rate of speed the cars would simply get up there and wait for that train to pass again. The only thing he could do under the circumstances was what he did—that was, to give between these crossings a slow enough time card so that the car, if blockaded at the first crossing, would arrive at the second crossing about as the freight train was getting by, and hence would not be detained there any length of time.

If he had operated his cars at the rate of 20 miles an hour he could not have made the second crossing ahead of the freight train which blocked him on the first crossing. The final solution of the problem presented was to take up the tracks between the first and second crossings and relay them so that they paralleled the steam road, cutting out the first and second crossings and effecting a crossing so as to reach the most populous part of the town at a distance of something like a mile further away. The track then doubled back on the opposite side of the steam road for a distance of about one-half mile to reach certain manufacturing establishments located at that point. By doing this they were enabled to increase the speed of the cars and largely increase their traffic by taking the operatives night and morning to and from the manufacturing establishments in question, and the people all along the line patronized it much more extensively than they did, simply because of the increased speed.

One peculiarity of the operation of cars in small towns is the fact that each individual patron thinks the road is run especially for his benefit, and consequently, that the cars can stop anywhere, and ladies think that they can signal the car and then go back and put on their things, and the car ought to wait while they do it. People who reside along the line think that the conductor ought to know where they get off without saying anything to him; consequently, they visit with their neighbors on the car and chat along; by and by the car goes by where they live two or three blocks, and they look up and find that they have been carried by and are highly indignant at the conductor. It takes a great deal of education to remove this impression. I recall an instance in my own experience where, having resolved on putting into effect a higher rate

of speed for the cars, I had large signs made, which were attached to poles at the corners of certain streets on this particular line, two blocks apart. On these signs were painted the words, "Car stops here," and I gave instructions that the cars were not, under any circumstances, to stop except at those points.

The result was that I was kept busy for a week or more explaining to indignant citizens that in order to serve the interests of all to the best advantage it was necessary to adopt a higher rate of speed, and therefore, in order to make the schedule time, cars could not stop except at the points indicated. Finally, after several weeks' trial, the people got used to the change and found it so satisfactory that all signs of discontent passed away and the traffic on the road increased considerably, due, as most people said, to the fact that they did not have to stop at everybody's door, and consequently could get down town in much less time. At cross streets where there were numerous carriages, truck teams, bicycles, etc., passing, I put up danger signals and signs on which were painted, "Cars must stop here," and required all cars to come to a stop at these points whether they had passengers for them or not, in this way materially reducing the liability to accident incidental to a high rate of speed.

Another precaution taken was to absolutely prohibit anyone riding on the front platform with the motorman. It seems almost unnecessary to mention this, but in numerous towns that I have visited I have found passengers riding on the front platform, and that at all times, and it is absolutely certain that cars cannot be operated at a high rate of speed with safety unless the motorman has nothing to distract his attention from the work in hand. When this rule is first put into effect there is a universal protest against it on the part of patrons of the road, but it should be rigidly adhered to, and they soon get accustomed to and do not mind it. Several managers with whom I talked in regard to putting this rule into effect raised the point that, in order to encourage traffic, they must give citizens the entire run of the car and practically let them do as they please. Where this latter rule is followed, however, discipline is lax, accidents are of frequent occurrence, and the road presents a slipshod appearance, which is not inviting, to say the least. If people are made to understand that it is necessary for them to observe certain rules in order to co-operate with the company to secure safety in operation there will be little or no difficulty in the enforcement of the few requirements necessary to insure the greatest freedom from accident.

Insurance companies offer to insure street railways in the smaller towns against accidents for from 2 per cent to 2½ per cent of the gross income, and are apparently not overprosperous at that rate. It seems to me that this is a direct reflection on the operation of this class of roads, for, following out the few simple rules laid down above, during five years that I operated a street railway in a town of 40,000 inhabitants, the amount paid for injuries and damages in any one year never reached one-half of 1 per cent of the gross receipts, and usually did not exceed one-quarter of 1 per cent, and yet we were operating the road, except on one crowded thoroughfare, where we slowed to 6 miles an hour, at an average speed of about 12 miles an hour, including stops, making the actual running speed of cars about 50 per cent higher. Probably many railroad men when they see this will immediately want to know what fender we used to make our accident list so small, and as a reply to them I will say that we used no fender at all, except that best of all, a competent and vigilant motorman, who was carefully selected and trained for his duties before being given a car, and careful and systematic attention to the brake mechanism.

Another peculiarity of operating cars in small cities is the irregularity of about one-half the traffic. There is a certain constant load at what may be called the working hours, in the morning, at night and at noon, and this is supplemented or decreased according to the time of the year, condition of the weather, etc. From about 10 o'clock in the morning until 11:30 cars coming from the residence districts to the business center of the town often have very light loads and occasionally, as the boys say, "turn a goose egg;" that is, do not register a single passenger. We plotted a curve of traffic at different seasons of the year, taking a week's record at each time, and subsequently kept a check on this curve, and, as we all know that the best economy is obtained by getting the low points and peaks out of this curve, the problem presented is how to get people to ride during these idle hours was an interesting one.

The stores would have mark-down sales, which would bring the ladies out in force, and, as they opened at 8 o'clock in the morning on these days, the ladies would supplement the ordinary travel during the heavy-load hours, and often tax the regular cars to their utmost. It finally occurred to me that if I would take the merchants into my confidence it might solve this difficulty very nicely, so, as the opportunity presented without making any marked effort in the matter, it was suggested to the different merchants that if they would arrange to have their sales open at 10 o'clock, instead of 8, when they opened their stores, they would help us and give the ladies a chance to get their housework out of the way before coming down town, and they would therefore feel free to stay longer and shop more than they would if they had to hurry home and get their housework out of the way before dinner.

They readily fell in with the suggestion, and I think it was profitable to them, as it certainly was to us. Of course, the manager of a road in a large city would not be obliged, nor would he have the time to study these finer problems, but in the smaller cities it behooves the manager of the street railway to thoroughly familiarize himself with every detail that will affect the traffic of his road and cultivate the friendship and good-will of the storekeepers, and by keeping in close touch and working together the irregularity of the traffic can often be eliminated.

(To be Continued.)

Plans for a Chicago Subway

President Roach, of the Union Traction Company, presented the Street Railway Commission with detail plans for a subway under the down-town streets of the city, at its meeting July 25. Mr. Roach had previously outlined his plans to the Commission, and at their invitation presented his plans in detail on the date mentioned. President Roach has intimated that if the subway is built by the Union Traction Company, the franchise will have to be perpetual. He positively refused to consider a twenty years' proposition, and stated that if the subway is constructed it must be on terms that will settle the problem for all time.

President D. G. Hamilton, of the Chicago City Railway, was present, and listened with deep interest to the proposition advanced and criticisms made.

The Metropolitan Street Railway Company, of Kansas City, is now operating five cars painted a Pullman brown, both outside and inside. The cars are being run as an experiment to test the wearing qualities of the new color, and with a view to its adoption as a standard with the company. Its cars are now painted a light color, but this requires much care and constant retouching.

CORRESPONDENCE

The Characteristics of a Successful Street Railway Manager

Metropolitan Street Railway Company
New York, July 2, 1900.

Editors Street Railway Journal:

I have read with much interest the editorial in your June issue describing the "Characteristics of the Successful Street Railway Manager," and heartily indorse all that you say therein as being strictly true. If the imaginary and rare man you have depicted is possessed of good health—one very important element in success—there is nothing left to be desired. As I review the characteristics you have named, they are:

First—Honesty and loyalty.
Second—Sincere regard for employees.
Third—Force and decision of character.
Fourth—Organizing ability.
Fifth—Diplomacy in dealing with the public.
Sixth—"Horse sense" concerning engineering problems.
Seventh—Determination never to undertake an impossible nor to abandon an achievable thing.

These seven virtues combined in one person would constitute, from my point of view, "the very figure of a man," and yet I can conceive conditions under which he might not be a success in managing a property. We managers are now and then apt to lose sight of the influence of our surroundings and associations, and vaingloriously appropriate all the credit for successes which are the result of co-operation of various kinds; for, powerful as the modern manager is, there are limits set to his authority by the superior power of ownership. Hence, I can conceive such a man as you have described making a failure with a property, the ownership of which was in the hands of selfish, narrow-purposed men, uninfluenced by those broad public considerations which are so interwoven with the affairs of public service corporations.

It may be answered that to allow himself to become associated with such a class of owners would in the first instance argue that the manager lacked the virtues of the seventh class. The real character of owners, however, is not a matter of record. One does not demand a certificate of character from an employer, indorsed by the last servant, and there is no way a manager can ascertain what the owners are like until he has tried them, off and on, in fair weather and foul.

And so the thought has come to me, in thinking the thing over, that, after all, the manager is unlike the poet, for he is made, not born. Put the man, born with all the characteristics named, into bad company, and the chances are nine to ten you will spoil him. I have no sympathy with those impossible men who have never worked out their potentials because they have never been in the proper kind of company, but, with my conviction that there are more good and able men in the world than is generally supposed, I can only account for the small evidence they give of their existence by the probability that they are in bad company.

One might go even a step further with this idea and arrive at the conclusion that a pretty fair kind of a manager, without some of the seven virtues, could be made by the loyal and liberal co-operation of an enlightened and public-spirited ownership, but to pursue the thing too far would be looking at the manager through reversed binoculars, and, being of the class myself, I do not care to inaugurate a habit of this kind.

H. H. Vreeland.

June 30, 1900.

Editors Street Railway Journal:

I am much interested in an editorial appearing in the Street Railway Journal of June 2, this year, entitled "Characteristics of the Successful Street Railway Manager." I have read the same carefully, and certainly indorse fully all that portion directly referring to what the manager should be, but is it true that there is a great scarcity of competent managers? My impression has been the reverse. It appeared to me that the recent consolidations all over the country had thrown out many managers, some of whom, at any rate, it would seem must be men of ability. I placed an advertisement in the Street Railway Journal in two issues which brought only two replies, and these from small properties wanting "a capable manager for $75 or $80 per month." This should not be considered as a reflection on the value of the paper as an advertising medium, but shows that there is a surplus of men capable of handling large properties. These offers were, of course, courteously declined; a man of any ability can double that loafing in this country.

I will not tire you with a long recital, but I believe that I can fill every requirement outlined in the editorial referred to, and believe that I can make it so appear to any syndicate requiring such a manager if I can get into communication with them. If you know of any such I should be glad to be furnished with their address. I am a man who studies his business and is always prepared for the emergency before it arrives, and I have been successful in the extreme in maintaining amicable relations with city officials, the public and the press without giving away all the company's property, and have been successful in the handling of employees, and yet retaining their good will. This latter was exemplified here when giving up my position in the reorganization, the employees made me a present and still seem to try if possible to show me greater deference than when I held their jobs in my hand. This was a surprise to me, as I had always been very strict, and would never tolerate inattention to duty, yet careful that employees should all be treated justly and no favorites. I have also had to face the "stockholder's son" and kindred propositions, too, but I would simply tell them that all I could do was to give them a place—*they must hold it*—and turn them over to their superintendent. Prompt decision is one of my strong points. I have always made it a point to have my business so well in hand that I can say instantly what I will do—I have a strong contempt for a vacillating business man. I combine the engineer with the business man—know thoroughly how things should be done and how to pick the cheapest and the best way, yet understanding that the ever-present problem in railway management is not simply what can we do, but rather *what can we do without.*

John Smith.

A Note of Warning on Polyphase Transmission

Boston, Mass., July 16, 1900.

Editors Street Railway Journal:

I have noted with the greatest interest the long array of electric railways using rotary converters, as published in the Street Railway Journal for June. So long a list augurs well for the practical advantages of polyphase power transmission for railway purposes; and a little inspection brings into prominence the fact that these roads represent almost every possible case of transmission to rotaries. Some of them merely utilize transmitted power in a central station; others are long roads, winding from city to city, and fed from sub-stations deriving their power from a long transmission line, linking them with a main

generating station; and still others represent various phases of distribution, from a huge urban station to its auxiliaries. All these applications of the general methods of power transmission may be of great value in electric traction, but as a consistent advocate of polyphase apparatus and methods, and an earnest student of the problems arising from the enormous growth of electric traction, I feel it my duty to sound a note of warning—a warning directed, not against power transmission to rotaries, but against making a fetish of any method, however useful intrinsically.

I regard it as certain that many of the roads enumerated in your imposing array are transmitting power wisely and economically, but there is, on the other hand, little doubt that some of them are wasting their substance fruitlessly in zealous endeavors to follow the latest fashion. It is no more reasonable for all roads to use the same engineering methods than it would be for all their superintendents to wear white bell-crowned beaver hats as a badge of office.

Now, in point of solemn fact, it is sound engineering to transmit power only when such transmission has a logical, economic reason for existence. Every such plant necessarily wastes power in the transformations necessary to its operation, and must show due cause therefor in an ultimate saving or stand condemned.

In the ordinary use of rotary converters there are to be encountered the aggregated losses in the transformers, the lines and the rotaries themselves. In these are consumed under ordinary conditions of load from 20 per cent to 25 per cent of the energy input. This loss is irretrievable, and must in some way be compensated if an economic result is to be attained. For every 75 kw to 80 kw delivered by the rotaries 100 kw must be delivered at the generators, and in addition one must buy and install transformers and rotaries nearly equaling in output the main generators, besides installing the transmission line itself. That is, to deliver 75 kw or 80 kw to the lines one must have a rotary converter of that capacity, transformers for the same, and a 100-kw polyphase generator at the other end of the line. If one can drive that generator by cheap water power the outlook is generally comforting, but when it is deliberately proposed to drive it by steam power there must be a truly prodigious saving somewhere to offset the necessary and unavoidable losses. If one is dealing with 10,000 kw, instead of 100, the need of showing a saving is by so much the more imperative. Now, it is undoubtedly true that power can be generated much more cheaply on a large scale than on a small one, and in this fact lies the key to the situation; but unless the saving is in the neighborhood of 25 per cent or 30 per cent there is a hard outlook for economy in using rotaries, and the bigger the system the more difficult is it to show such a saving. In considering the application of transmission methods on a large scale a good preliminary step is to consider the effect on the economy of a great station of merely putting up a heavy partition wall, dividing the station into two equal and symmetrical parts, and forbidding employees to cross from one to the other upon any pretext without an hour's notice of their intention. Unless the total cost of the year's output would be increased at least 25 per cent by this simple change sufficient reason for the use of rotaries, rather than distributed stations, will have to be looked for with a search warrant. In rare instances some one site for a station may have great natural advantages and lead to economic results that could not otherwise be approached, but it is not safe to jump at such a conclusion or to accept it without heavy preponderance of evidence, particularly in view of the fact that even sub-stations require costly space and considerable attendance. If in the course of events it becomes generally feasible to use alternating motors for traction purposes, the case will resolve itself into a simple transmission problem, and a favorable solution will not be difficult to reach. At present, as I have endeavored to point out, the application of transmission methods to traction work involves economic losses so considerable and serious that one will do well to stop and think twice before incurring them. In very many cases they can be more than offset by gains due to the very processes that involve them, but it is worth while to call forcible attention to the fact that such is by no means a foregone conclusion. Louis Bell.

Street Railway Statistics and Municipal Ownership

Cleveland, Ohio, July 17, 1900.

Editors Street Railway Journal:

I am anxious to get statistics for the last five years on the mileage, number of cars and capitalization of the street railways of the United States, and would also like to know in which issues of the Street Railway Journal you have published articles on municipal ownership of street railways. F. S. Vernon.

[Answer.]

Statements of cars, mileage and capitalization of American street railways for the past five years can be found in the Street Railway Journal for July, 1895; August, 1896; October, 1897; February, 1899, and June, 1900.

We have, of course, published a great many articles on the subject of municipal ownership and operation of street railways, and almost every number of the Street Railway Journal has contained something on this subject, but possibly the most important articles are in the following list.—[Eds.]

May, 1897. Editorial on "Street Railways vs. Municipalities."

September, 1897. "Municipal and Private Ownership and Operation of Street Railways. A Study of Results and Possibilities," by Edward E. Higgins. This is, so far as we know, the most extended defense of private ownership which has been made in this country.

September, 1897. Editorial entitled "Municipal vs. Private Management of Street Railways."

November, 1897. Paper by P. F. Sullivan on "Municipal Ownership and Operation of Street Railways."

December, 1897. Editorial on "The Case for Municipal Operation of Street Railways."

August, 1898. "An Act Relative to Street Railways," passed by the Massachusetts State Legislature.

May, 1899. Editorial discussion on municipal ownership.

May, 1899. "Municipal Ownership in Detroit."

August, 1899. Editorial and article on "Proposed Solution of Municipal Franchise Problem," from Allen Ripley Foote's work upon "Municipal Public Service Industries."

April, 1900. "Some Differences Between American and British City Transportation Methods," by Edward E. Higgins. This is a complete refutation of the prevailing popular belief that British methods of dealing with street railway companies means greater revenue to the public treasury or improvements in any way as compared with "the American system."

On July 19 the Mayor of Montgomery, Ala., vetoed the ordinance to prohibit the operation of street cars in the city of Montgomery without conductors. The Council passed the ordinance July 9, with an amendment excepting roads that did not operate six cars. The Mayor vetoed the ordinance on the ground that it was illegal and inoperative, in that it excepted roads not operating six cars. The Mayor thinks that if the safety and convenience of the public demands conductors on some cars they are necessary on all, and he is opposed to any discrimination between the railroads operating cars in this city.

STREET RAILWAY JOURNAL

PUBLISHED WEEKLY BY

THE STREET RAILWAY PUBLISHING COMPANY

MAIN OFFICE:

NEW YORK, BEARD BUILDING, 120 LIBERTY STREET.

Chicago Office: Monadnock Block.

Philadelphia Office: 929 Chestnut Street.

London Office: Hastings House, Norfolk St., Strand.

Long Distance Telephone, "New York, 4044 Cortlandt."

Cable Address, "Stryjourn, New York."

TERMS OF SUBSCRIPTION.

In the United States and Canada.....$4 00 per annum

In all Foreign Countries, per annum.....{ $6.00 / 25/ / 31fr.

Subscriptions payable always in advance, by check (preferred), money order or postal note, to order of C. E. WHITTLESEY, Treasurer.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our news columns.

All matters intended for publication in the current issues must be received at our office not later than Wednesday of each week.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

It may be news to some of our readers to know that funeral cars are now running regularly on street railway lines in Chicago, Cleveland and St. Louis. Elsewhere in this issue we publish a description of some cars now in commission, and of their mode of operation. As yet the system may be said to be in an experimental stage, as nearly all the cars have been made by the traction companies themselves, but their success wherever they have been introduced will probably compel the regular manufacturers to take up the matter before long. The introduction of an innovation of this kind must necessarily be somewhat slow, as there is probably no custom of any community which is so regulated by conservatism as that relating to the disposal of the dead; but the reported daily use which comes from Chicago indicates that already there are many persons who prefer the comfort and convenience of the service to the conventional hearse and its accompanying "procession." The funeral car seems to be peculiarly adapted to the use of the larger cities, where the cemeteries are usually located in the suburbs and at a considerable distance from the majority of the residences. Where this distance is several miles every consideration points to the use of the trolley car in preference to the carriage. In the city of Mexico funeral cars, run by horses, have been in use for a long time, and the returns last year from this service were as much as $80,000, in the currency of the country, or nearly 5 per cent of the gross receipts. It may take a long time to introduce the system to any extent in this country, but it is a step in the right direction, and is worthy of serious consideration.

The attention of street railway managers may well be given to the admirable work done by Allen Ripley Foote during the past three or four years in pointing out and codifying certain important principles which should govern contracts between municipalities and public service corporations, such as street railway, electric lighting and gas companies, etc. This work appears in excellent form in a series of bills prepared by Mr. Foote at the request of the Ohio State Board of Commerce for presentation to the Ohio Legislature at its last session, and while action upon these bills was deferred until the next session, it is expected that they will be taken up for consideration next winter.

The essential provision of these bills are as follows:

1. Bonds issued by a municipality for the establishment of a public service plant shall be secured only by mortgage of the plant itself and the franchises for operation. In other words, the general credit of the city shall not be placed behind these bonds, but they must stand or fall upon their own merits and earning power.

2. No public service owned by a municipality shall be sold for less than cost. If the service does not pay at the prices originally established, these prices must be increased. The general body of taxpayers must not be called upon to help pay for a service to a private user.

3. The true and entire cost of service, whether given by a private company or by the municipality, shall be determined by a State Auditing Department, to be established, and shall include the following terms:

a. The full operating expenses.

b. A sufficient provision for depreciation, for losses from fire, and for accidents of every kind.

c. Taxes paid (in the case of private companies) or relinquished (in the case of municipalities), these taxes including any special bargains concerning franchise taxes which may be made between municipality and company based on a payment of percentages on gross receipts.

d. Interest on the full amount of actual investment at the rate per cent paid by the municipality on its bonded debt.

4. To the cost of service as above specified, there shall be added in the case of enterprises owned and operated by the municipality a provision for a sinking fund sufficient to pay off at maturity the bonds issued on investment account.

5. All surplus earnings over and above the true cost of

service, as defined in paragraphs 3 and 4, are to be regarded as the true profits of the enterprise.

6. Out of these true profits, when earned by a private company, the latter may pay upon its true investment a rate per cent double that paid by the municipality on its bonds.

7. If a private company adopts a system of profit sharing with its employees, it shall be entitled to earn and pay to the employees the same rate per cent upon the wages earned by them as the company earns on its investment

8. All surplus profits, after making the distributions provided for in paragraphs 6 and 7, are to be divided equally between the municipality and the company.

9. The determination of the investment value to be used as a basis for the foregoing computations shall be determined originally by appraisement or by arbitration. Additions shall be made in a manner specified by the municipality.

10. The price for service to be paid by users shall be fixed by the municipal council for a period not less than five nor more than twenty-five years, and the prices so fixed shall be computed on the basis of cost, and must be such as to produce an annual revenue sufficient to fully pay all costs and to yield the company its authorized share of profit.

The above programme is clear, logical, and seems to be fair to all parties in interest. It embodies many of the principles which we have several times recommended to street railway companies which have short time, imperfect or otherwise unsatisfactory contracts with municipalities at present, and we believe that where such a programme is adopted there will be a cessation of friction between the municipality and the companies. The difficulties in the way lie in the opposition of the professional politicians, who do not, as a rule, care to see a permanent settlement of these questions, but prefer to have them left open for possible "strikes" when the political exchequers are low. The public in general, however, will be greatly benefited by contracts of this character—far more so than will be the case where municipal ownership, with all its crudities and imperfections, is adopted, and many of the most intelligent and fair-minded of the advocates of municipal ownership grant that the principles above laid down would be satisfactory to them as a substitute.

Concerning Tractive Resistances

Despite all that has been written upon this very important topic, engineers are still confronted with a degree of uncertainty as to the exact facts, which is anything but comforting. It is the purpose of these lucubrations to exhibit the present state of general ignorance and to point out the line which experiments should take in order to clear matters up. In ordinary tramway practise the engineer takes his medicine, and says no more about it—the conditions change every time the street is torn up and repaved or resurfaced by a new gas company or an overzealous street department. When, however, he is confronted by the problem of planning a high-speed line, and proceeds to look up the available data on train resistances, he finds himself up against a pretty tough proposition. Suppose one starts by assuming a 100-ton train and a speed of 100 miles per hour, and takes the data now available, what conclusion will he reach? Passing by some of the earlier formulæ, we will start with the well known results of Wellington, founded upon a legion of experiments. Taking our train as composed of five cars, we set gaily to work, and promptly get out a tractive resistance of no less than 97 lbs. per ton, which is equivalent to an output of 2586 hp. This is a cheerless outlook, indeed, so we make a mental reservation to the effect that Wellington's data do not quite represent modern results, and hunt up Barnes' formula, deduced from a large amount of high-speed work with locomotives. This seems pleasanter, giving as it does a net 20 lbs. per ton, just 533 hp for the job. But which is correct? It would be decidedly unpleasant to advise, say a 600-hp equipment, and then find that Wellington was right, and it would be annoying to build a 2500-hp locomotive and find it nearly five times larger than required. So, in this dilemma we look over the files of the STREET RAILWAY JOURNAL, and hunt out Lundie's results. They look reasonable, and applying them to the case in hand we find that 34 lbs. per ton is about right, calling in all for 907 hp. This seems more agreeable, and we are just settling down to a contented frame of mind when someone unkindly calls our attention to a batch of very careful tests made in France about fifteen years ago. We cannot entirely reject these, and, applying the resulting formulæ, find to our horror that 58 lbs. per ton is the figure indicated, and that we shall certainly need 1546 hp to pull that wretched train.

Now, bearing in mind that each of the formulæ represents the results of painstaking experiments, it certainly seems queer that they lead to results so discordant. To say what is true enough, that they are horrible examples of the dangers of extrapolation is begging the question, for what we really want to know is the reason why the formulæ seem to go crazy and talk nonsense as soon as they get out of sight of the experiments.

To begin with, train resistance is certainly a very complex variable, and to assume that it can be correctly represented over any considerable range by a linear, parabolic, or hyperbolic, relation between the co-ordinates, is altogether gratuitous. To analyze the total resistance roughly, it is composed of three separate elements, varying in relative importance as the speed varies. First comes the track resistance proper, *i. e.*, the resistance to dragging the turning wheels over a track which is far from being frictionless; second comes the drag of journal friction, which is comparatively simple; and finally the air resistance, more complex than either of the others. The first mentioned factor is the predominant one at all low and moderate speeds. The third at these speeds is rather small, but controls the situation at very high speeds. The second is, fortunately, tolerably stable and not large enough, ordinarily, to complicate the situation.

We may now further analyze each of these factors of the resistance. The track resistance is made up in the main of pure rolling friction, small and fairly steady; joint friction, rather large and variable; flange friction due to jarring and rocking of the trucks and to wind, large and exceedingly irregular, and finally, the work against gravity, due to irregularities and flexure of track, very variable and at times very large. It is impossible to define the exact relative importance of these factors, but it is safe to say

that the friction of bearings and the rolling friction of wheels upon track, particularly the last named, cut a rather small figure in the total. Their sum constitutes the principal component of train resistances at extremely low speeds, particularly in the case of long and lightly loaded trains. It probably does not exceed 3 lbs. per ton, to judge from the evidence of various investigations, and, perhaps, may be somewhat less. Moreover, it is likely to remain fairly uniform irrespective of speed. The flange and gravity components may be estimated roughly from the increment of the track resistance as the speed rises within moderate limits, for the air resistance in case of a heavy train is so small that while it cannot be neglected it is not likely to involve uncertainties considerable enough to introduce material errors. With a heavy train at 10 miles to 15 miles an hour the head pressure due to air resistance is unlikely to exceed about 1 lb. per ton, and the characteristics of the various formulæ indicate that at such speeds the factors we are examining have already exceeded the pure friction and probability range about 4 lbs. to 5 lbs. per ton. Their rate of increase is a very uncertain quantity, indeed. On a poor track the jarring and swaying increases rapidly with increased speed, and this must cause a very considerable rise in the amount of power required. On the other hand, a train upon a good, or fairly good, track sometimes seems to steady down at high speeds, so that it seems to run quite as smoothly at 60 miles per hour as at half that speed. While the real facts of the case have not as yet been ascertained, there seems to be considerable evidence that on the whole these resistances do not increase directly as the speed, but at a variable and finally decreasing rate, so that at very high speeds they are scarcely, if at all, greater than at 10 miles or 15 miles per hour. In other words, at very great velocity, the running gear, and perhaps even the track, works more smoothly than at low speeds. This view is borne out by the very extraordinary fact that of the comparatively few experiments at speeds above 75 miles per hour all give values of the total resistance so low as to leave no room for a considerably increased track resistance unless the air resistance is much smaller than there is the slightest reason to suppose.

Of the air resistance we have now considerable knowledge, enough to say with certainty that it does not increase as the square of the speed, but at a much less rate. Crosby's experiments, of course, show an almost linear relation between speed and air pressure, but these were made upon short bodies, no more than two or three diameters long. Now, the air resistance to a train is composed of two distinct parts—first, the head pressure, and second, the eddy or wave pressure along the sides. The first may reasonably be expected to obey some fairly simple law, but the second is an altogether unknown function of the velocity and length of the train. Now, even as regards the head pressure, while it is true that doubling the speed of a train doubles the amount of air per minute pushed aside by its front, there is a great deal of doubt as to the velocity acquired by the said air and the actual work expended upon it; and, when we consider the resulting eddies, unknown as to velocity and somewhat uncertain as to direction, it is small wonder that air pressure in general is a somewhat uncertain quantity. There is a strong probability that the value of the eddy resistance passes through a series of maxima and minima, as does the wave resistance of a ship, the values of these depending on the velocity, length of train and perhaps even the length of individual cars. Data bearing upon this phase of the subject are greatly needed.

In taking up the application of resistance formulæ to high-speed electric work, it must not be forgotten that motor gearing, if gearing be used, is a very material matter, and that if the number of motor-driven axles is considerable, an entirely new factor enters the calculation. There is some good reason to believe that the grinding friction of a driving wheel is entirely different from the rolling friction of a trailing wheel, so that where minimizing the power at high speed is the controlling consideration, the fewer driving axles the better.

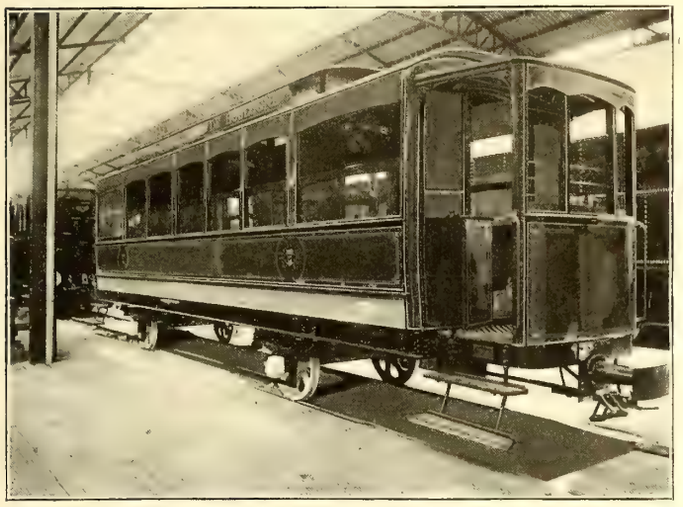
Now, all this is intended to point out as nearly as may be what are the uncertain factors in train resistances at the high speeds to which electrical traction must in the course of events tend, and to stimulate if possible the research that is necessary to finding out the conditions upon which success depends. There is much to be done, and many hands are needed to do it. First of all, it is desirable to get data on the values of the track resistances at various speeds. Second, we need, and need badly, a redetermination of the air resistances on a large scale; if possible, direct dynamometric measurement of the power required to tow at the end of a very long cable a car having a front of definite area and shape. Finally, the head resistance should be as far as possible differentiated from the eddy resistance by experimenting on trains of various lengths in some such manner as we have just indicated. With these data in hand it would be easy to deduce graphically the actual power required to drive a given train at any required speed within very wide limits. We say graphically because it is extremely doubtful whether any formula simple enough to be convenient for reference would represent the experiments with sufficient exactness. The facts of the case are necessary not only to determine the absolute power required, but to indicate the best means of supplying it. It is certain that very high speed traction must in the nature of things come, and the sooner preparation is made for it the better, for failure in the first serious attempt would not only be costly, but would have a discouraging effect on future work along the same line. Meanwhile it may be noticed that we have vouchsafed no solution of the hypothetical question we propounded at the start. The reason for such mental abstinence should by this time be tolerably clear. In the present state of the data we must firmly decline to hazard anything more authoritative than a guess—sometimes called an estimate by those who desire to appear wise in the eyes of their fellowmen. But our guess is that when the first well designed train of 100 tons is run at 100 miles per hour the total resistances will not exceed 20 lbs. per ton of weight.

The Grand Rapids Railway Company, Grand Rapids, Mich., has issued a neat little folder for the benefit of its patrons. A map of the system is given, but nearly the entire space is occupied by reproductions of views to be seen from the trolley cars. One page is devoted to the details of a trip around the city, which will give the passenger a chance to see the greater part of the city, with stopovers at the parks, for the sum of 20 cents.

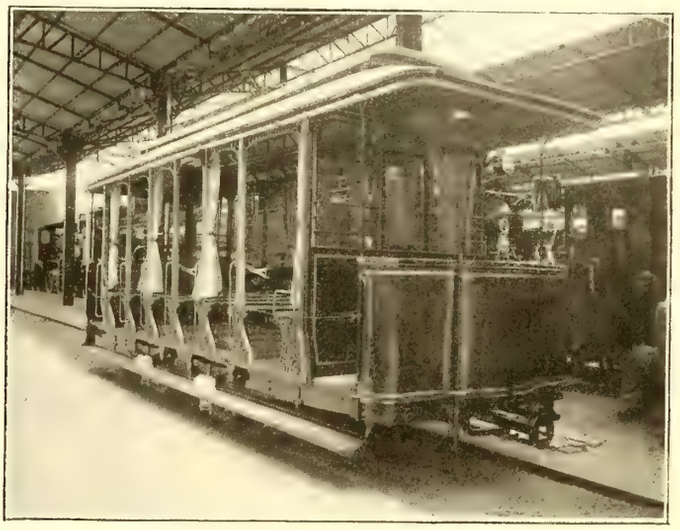
Paris Exposition Notes

[*From Our Regular Correspondent.*]

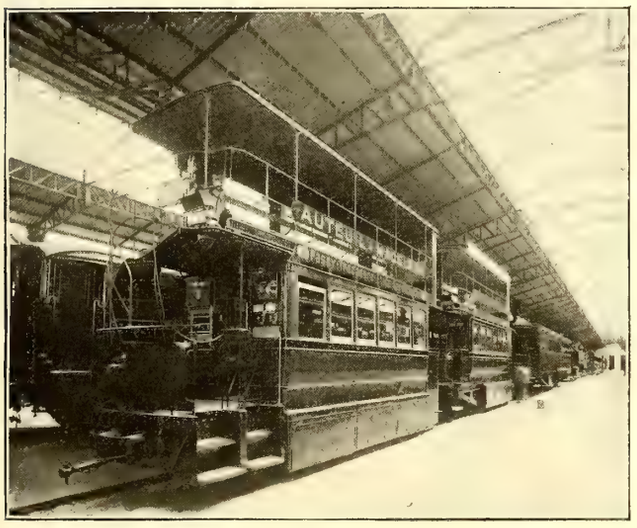
Since the last appearance of the STREET RAILWAY JOURNAL, the Transportation Exhibition, both on the Champs de Mars and at Vincennes, may be said to have been completed and put in such a shape that the visitor can at last make for himself a fairly thorough and comprehensive study of what is shown in each group. Best of all, the section of the official catalogue, which comprises Group 6, dealing with civil engineering and means of transport, has at last made its appearance in the shape of a bulky volume of several hundred pages, which, however, are not numbered consecutively. As the material under each of the several classes in the group is treated separately, however, the catalogue is easier for reference than might appear at first sight. Preceding the section which deals with Class 32, or material for railways and tramways, is a very interesting summary of the situation in France. A large part of this deals necessarily with steam railroads, but there is an interesting section of three or four pages which treats more particularly of street railways. There is also a little section which deals with what are called "railroads of local interest," or which, perhaps, in England would be called "light railways," using a narrow gage. Many of them are really rural street car lines. Of these light railways, it would appear that there were in France when the figures were compiled, about two years ago, 4200 km in operation and 563 km under construction. Under the head of tramways, the total mileage in operation, given under date beginning 1899, was 3282 km; while another table, as of 1898, gives in operation, 2908 km of different gages, and 1351 km under construction. It is worthy of note that of the mileage thus presented, 1988 km was of one meter gage in operation, and 1152 km under construction. It is stated that for the track the types of rail in use are Marsillon, Broca and Vignole, of weights varying from 14 kg to 48 kg per meter, while in cities where self propelling vehicles are used weighing as much as 20 tons a track weighing as much as 50 kg to the meter is in use. According to another table, at the beginning of 1899 there were in operation in France 317 km of street railway operated electrically, of which 298 km were overhead wire. These figures have, of course, been greatly increased since the data were compiled for the catalogue, and this is equally true of the professional and industrial census given, reported for 1896, when, it is stated, some 4400 persons in France were employed in building locomotives and materials for railways coming within this class. It would seem that the data could easily have been made more complete and closer to date, but in view of the inordinate lateness with which the catalogues have appeared we ought to be profoundly thankful that no such cause for further delay was interposed.



TYPE OF CAR ON BOIS DE BOULOGNE TRAMWAY, VINCENNES



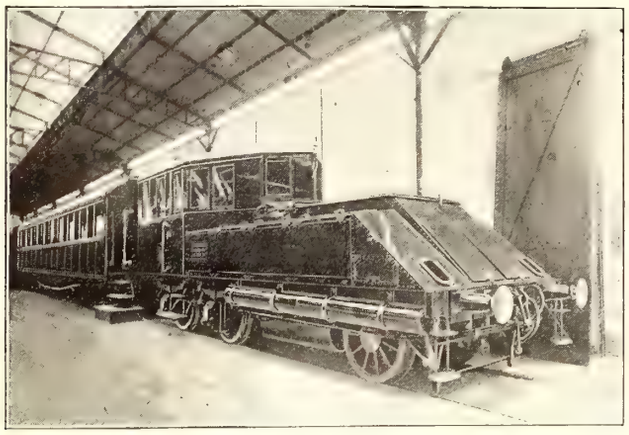
ITALIAN OPEN TROLLEY CAR, VINCENNES



COMPRESSED AIR CAR, PARIS GENERAL OMNIBUS CO., VINCENNES

RINGHOFFER, AUSTRIAN TROLLEY CAR, VINCENNES

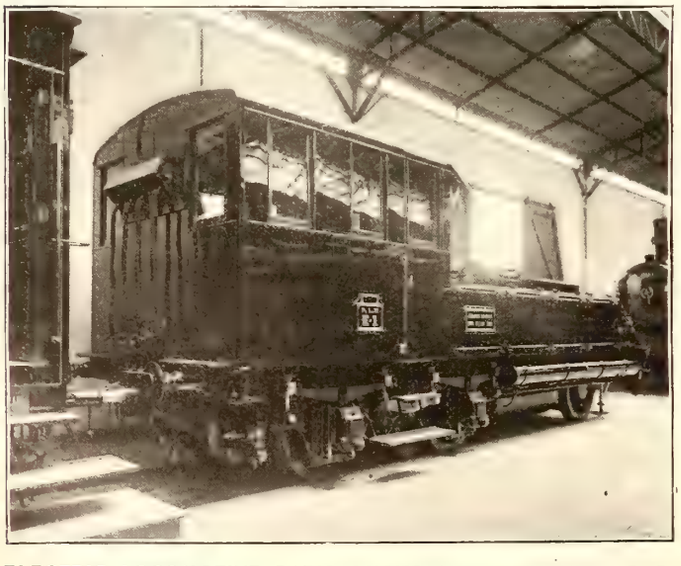
Taking up the catalogue as it stands, it would appear that there are nearly 500 exhibitors in Class 32, as follows: Japan, 2; Luxembourg, 2; Mexico, 2; Norway, 1; Holland,



END VIEW ELECTRIC LOCOMOTIVE, PARIS, LYONS, MEDITERRANEAN RAILROAD, VINCENNES

2; Peru, 1; Portugal, 4; Roumania, 2; Russia, 43; Servia, 1; South African Republic, 1; Sweden, 1; Switzerland, 7; Turkey, 1; France, 112; French colonies, 9; Germany, 25; Austria, 23; Belgium, 23; Bosnia, 1; Spain, 2; United States of America, 161; Great Britain, 24; Hungary, 28; Italy, 12, making a total of 490. Of these, a large proportion deal with street railway apparatus and material. It will be noticed that the United States makes a much larger numerical exhibit than France itself, but this is somewhat deceptive as to the space occupied, France exhibiting actual material upon the tracks, whereas the American material consists in a great many cases of official reports and volumes of transactions, or photographs and drawings.

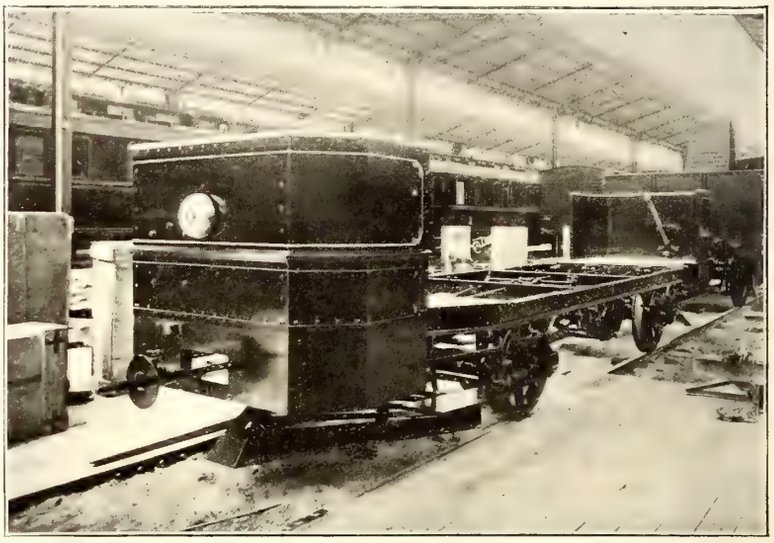
A great many views of the apparatus installed both in the Transportation Building of the Champs de Mars and at Vincennes have already been presented in the pages of the Street Railway Journal, pending a more elaborate and complete discussion, and a few others are now forwarded



ELECTRIC LOCOMOTIVE, PARIS, LYONS, MEDITERRANEAN R. R.

herewith. A liberal exhibitor in the French class is the Companie Générale des Omnibus de Paris, which exhibits a street railway car operated by accumulators, one of the steam type, one with an oil engine, and one of the compressed-air type. Some of these have been shown already, and a view is presented herewith of the compressed-air cars operated by this company. The air is stored at a pressure of 80 kg. per cm² in a reservoir below the floor of the car, and is reduced to 15 kg. per cm² before use in the motor. This ponderous double-deck car and its associate are in sharp contrast to the lighter recent types of trolley car and trailer, especially those of the single-deck type shown in the sample of car built for the Bois de Boulogne. This heavy compressed air car is also in sharp contrast with the light open trolley car, of which a view is here shown, built by Miani Silvestri & Company, of Milan, which is brought to notice in the Italian section on the tracks at Vincennes, and which is characterized by considerable lightness and grace of design. This concern is well known as a builder of rolling stock in Italy, and its name and material will be more or less familiar to readers of the Street Railway Journal. Another very interesting and handsome trolley car not included in the last batch sent of foreign exhibits at Vincennes is that shown in the Austrian section by F. Ringhoffer, of Prague, with a bent-loop trolley, as shown in the photograph.

The Miani Silvestri car is 7.84 m in length, and carries



TRUCK OF GANZ ELECTRIC LOCOMOTIVE, VINCENNES

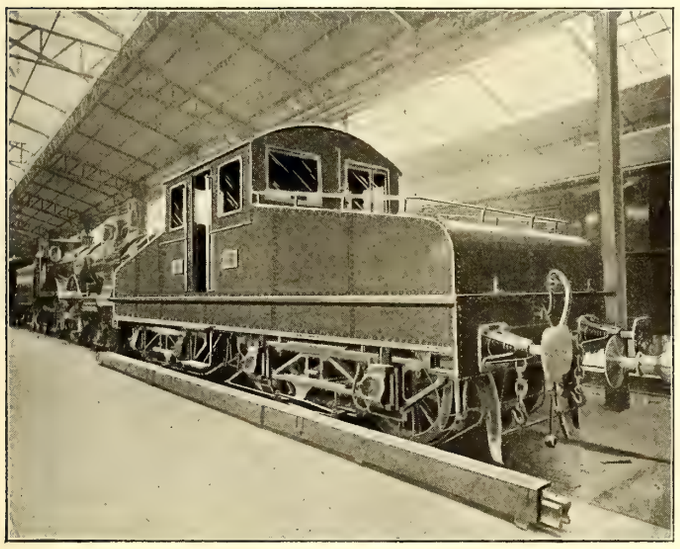
two General Electric motors of 25 hp each. It affords thirty-five seats, and the back rails of all but the end benches are reversible. The Ringhoffer car seats twenty-four passengers, and has standing room for eleven. It carries two motors of 25 hp each, of the Siemens-Halske make.

In previous correspondence no note has been made of the electric locomotives or locomotive trucks on view at the Vincennes part of the Exposition. It is well known that the various steam railroads of France have been experimenting in the direction of the utilization of electricity on their lines, particularly on urban stretches and around their terminal depots. And this is an important subject which demands more space than can be here given it, while so far very few details have been given out as to the actual construction and operation of the locomotives themselves, with which, it would appear, some very exhaustive tests are being made. During the earlier stages of the work on Electricity Building, the Railroad of the North had a very handy and effective little storage battery locomotive, with which a good deal of work was done, hauling and pushing carloads of exhibits into position along the temporary tracks through the building, and this in itself constituted a striking demonstration of utility in this branch of locomotion. But the machines on view at Vincennes are of a far more imposing character. Views of some of them are presented herewith, such as that of the Paris, Lyons & Medi-

terranean Railroad, that of the Paris-Orleans Railroad, and the truck exhibited by the Ganz Company, of Budapest.

The Ganz truck is in reality that of a motor car of ordinary size, but it has a lever brake. The total length is 8.26 m, and 3.10 m between centers of axles. It carries two motors of 25 hp each. The locomotive of the Paris, Lyons, Mediterranean Railroad, however, is something serious, as will be seen from its length and bulk. It is, moreover, equipped with two motors of 225 hp each, able to exert, it is said, between 500 and 600 hp.

With regard to the electric locomotive of the Orleans Railroad, its resemblance to those employed at Hoboken, N. J., and in the Baltimore Tunnel, will be at once noted by every American reader. It is due to the French Thomson-Houston Company, a fact which will account for its construction on these approved lines. It may not be generally known that the Orleans Railroad, which at present has its terminal at the very outskirts of Paris, and has therefore been most inconvenient to reach, has lately pushed its way nearer to the heart of the city and has erected a magnificent new station on the Quai d'Orsay. This prolongation of its track is 2½ miles in length, which will give an idea of the distance to be saved by the great majority of those who use the road. Over this stretch of track eight electric locomotives are to be used, of the type



FRENCH THOMSON-HOUSTON ELECTRIC LOCOMOTIVE, ETC., PARIS-ORLEANS R. R.

shown, and they have already been tested for their work in situ. Each locomotive has four driving axles with a motor in each, and weighs about 45 tons. These motors are of the G. E. 55 type, of 175 hp each. Each locomotive is easily capable of hauling passenger trains from the old station to the new in seven minutes, each train being estimated at about 250 tons. It is stated that 150 such trains will be hauled per day to and fro. The trains will arrive at the outer terminus under steam power, and a change of locomotive will be effected in two minutes. Current is to be generated at high tension and then delivered by two sub-stations—one at the Quai d'Orsay and the other at the Quai d'Austerlitz, where the old depot stands. The local current distribution system comprises a third rail external to the track and an overhead contact in the tunnel at the entrance to the Quai d'Orsay, so that each locomotive is provided with three sliding-shoe collectors and with two overhead trolleys, for the double service. Fuller details of all this highly important work will be given at the proper time.

In the immediate vicinity of this compact looking electric locomotive are a great many steam locomotives of the highest state of development, and the contrast both in shape and in mechanism naturally attracts a great deal of attention. It is not alone in electric locomotives that the initiative may be said to be due to American practise, for only the other day quite a dispute arose in the Chamber of Deputies owing to the fact that in one of the State railroad exhibits at Vincennes an American steam locomotive was

ELECTRIC LOCOMOTIVE FOR PARIS-ORLEANS R. R., VINCENNES

shown in all its glory, whereupon the inquiry arose why French locomotives were not good enough for systems in which the State itself had an interest. It is not to be understood that France or any other power of Europe is about to adopt the American style of locomotive, electric or steam, but there is no question that American practise as exemplified at this exposition is destined to have a great influence.

Compressed Air Cars in New York

Considerable interest has been aroused by the proposal of the Metropolitan Street Railway Company, of New York, to change the type of compressed air motors in use on its Twenty-Eighth and Twenty-Ninth Streets Railway. Reference has already been made to the fact that the Hardie motors are to be used on this line in place of the motors which have been employed, and which were described at length in the STREET RAILWAY JOURNAL for June, 1899. The reasons for this change can best be explained by a brief history of compressed air traction in this country during the last three years. About three years ago two manufacturing companies were making vigorous efforts in New York to solve the problem of the application of compressed air to street car service. One of these was the General Compressed Air Company, which was operating three motor cars on the 125th Street line of the Third Avenue Railroad Company; the other was the Compressed Air Power Company, which was owned largely by some of the principal stockholders of the Metropolitan Street Railway Company. These gentlemen were induced to become interested in compressed air traction, largely by the hope that independent compressed air cars could be used on the cross-town lines of the Metropolitan Street Railway Company, on which the installation of the underground conduit was practically out of the question on account of expense, and on which the installation of the overhead trolley was prohibited by the municipal authorities.

The motors used by the two systems mentioned, and which were popularly known respectively as the Hardie and Hoadley systems, were alike in that a high pressure, *i. e.*, 2000 to 2500 lbs. per square inch was carried in the air reservoir, but differed in practically every other respect. In the Hardie system, two long stroke (14 ins.) single expansion engines were carried on the car truck and drove

directly the wheels of one axle of the car, the other axle being connected to the driven axle by side rods. The Hoadley motors on the other hand were patterned more after an electric motor, so far as the application of the power was concerned. Each motor, of which there were two on each car, was of the compound type with short stroke (6 ins.), and drove a shaft carrying a pinion which in turn was geared to the car axle. The two axles were thus driven independently, the motors ran in oil, and the whole equipment did not differ very much in external appearance from an electric equipment. There were a great many other variations in practise between the Hardie and Hoadley systems, as in the method of reheating, etc., but those already mentioned are sufficient to characterize the two systems as radically different.

The satisfactory results secured by the Hardie motors on the Third Avenue line, as mentioned above, convinced the managers of the Metropolitan Street Railway Company that the patents of the General Compressed Air Company were essential in securing the best results in compressed air motor work. As a consequence, negotiations were entered into by which a new company, the American Air Power Company, was formed to consolidate the interests of the other two. The Metropolitan syndicate controlled the new company, and though certain modifications were made, the general characteristics of the systems used on the Metropolitan line remained the same, that is, the compound short stroke motor driving the two axles independently. Soon after the consolidation, the services of Robert Hardie were secured by the Compressed Air Motor Company, which was a licensee for Wisconsin and Illinois of the General Compressed Air Company, and whose stockholders still believed in the "locomotive" principle, as applied to compressed air traction. The scene of the competitive trial between the two systems was now transferred, the American air power motors being used in New York, while the Hardie motors were employed in Chicago. The Chicago motors were used on the North Clark Street road, to operate between 12 o'clock at night, when the cable of that line shut down, and 6 o'clock next morning, when the cable was again put in operation. The motors gave good satisfaction and frequently hauled a trail car, and sometimes two trail cars, with a total of 300 passengers on a train. The results secured were so much more satisfactory than those in New York that the Metropolitan syndicate decided that if success was to be secured in the latter city, it would have to be, by following the Hardie system as employed in Chicago. Negotiations were then entered into between the American Air Power Company and the Compressed Air Motor Company for a second consolidation of interests, and resulted in the organization of the Compressed Air Company, with Mr. Hardie as chief engineer for the consolidated company. Henry D. Cooke, the president of the Compressed Air Motor Company, was also elected president of the new company. This has resulted in the retirement of the old equipment on the Twenty-Eighth and Twenty-Ninth Streets lines, and the placing of an order by the Metropolitan Street Railway Company for the equipment of the line with the Hardie motors. The new motors for the Twenty-Eighth and Twenty-Ninth Streets lines are now being built, and will be in operation at an early date. It is the purpose of this article to describe the system as it will be employed on this road, as fairly representing the best American compressed air practise at the present date.

FIG. 1.—COMPRESSED AIR MOTOR CAR AND TWO TRAILERS, NORTH CLARK STREET, CHICAGO

The compressing station is located at the foot of West Twenty-Fourth Street, New York, western terminus of the line, and was fully described in the Street Railway Journal for June, 1899. It contains a 1200-hp engine, operating directly four-stage Ingersoll-Sergeant air compressor, with a capacity of 56,735 cu. ft. of free air per revolution, and compressing to 2500 lbs. per sq. in. This air is stored in a series of reservoirs of seamless tube flasks in the car house, from which the reservoirs on the cars are charged.

There are sixteen reservoirs on the cars, having an aggregate capacity of 55 cu. ft., and weighing 4340 lbs. Fourteen of these reservoirs are carried on the truck, and one under each seat. From these reservoirs the air passes into one common header, and from this header is a pipe passing to each end of the motor car. The flow of air through this pipe is regulated by a stop valve under the control of the motorman. When the motorman opens the valve at either end of the car, the air, which is still under 2500 lbs. pressure, passes from the valve to the reducing valve.

The reducing valve is illustrated herewith, and automatically keeps the working pressure uniformly at about 150 lbs. per sq. in., whether the storage pressure is at its maximum or its minimum or at any intermediate point. As will be seen, the reduction valve is balanced by a hydraulic packed piston (shown below the reduction valve) in such a way that a variation in the storage pressure, as would be experienced during a trip, does not affect the operation of the valve. Ordinarily, double valves are used for this purpose, but these rarely give a constant reduced pressure, with a variable high pressure; they also give trouble by leakage. As will be seen, there is a spring which tends to open the reduction valve, and whose pressure is balanced by a flexible disc, upon which the reducing pressure acts, tending to close the reducing valve. When this reduced pressure reaches a point sufficiently high to compress the spring, it seats the valve automatically.

The cap which closes the opening through which the valve is passed into its place is also a cylinder, in which is another hydraulic packed piston. The object of this piston is to enable the motorman to increase the working pressure for starting quickly from a state of rest. Its operation is as follows: A pipe connects the space *A* with the motor-

man's brake valve, and when the brake handle is moved to a certain position it bleeds the air from pocket *A*. The working pressure then acts on the under side of this piston to assist the spring in opening the valve. It now requires a higher pressure acting on this disc to close the valve against the combined resistance of the spring and this piston, which higher pressure enables the motor to start quickly. As soon as the motor has acquired the necessary speed, the motorman moves the brake handle to the normal running position, which restores the working pressure in the space *A*, so that the piston is now in equilibrium

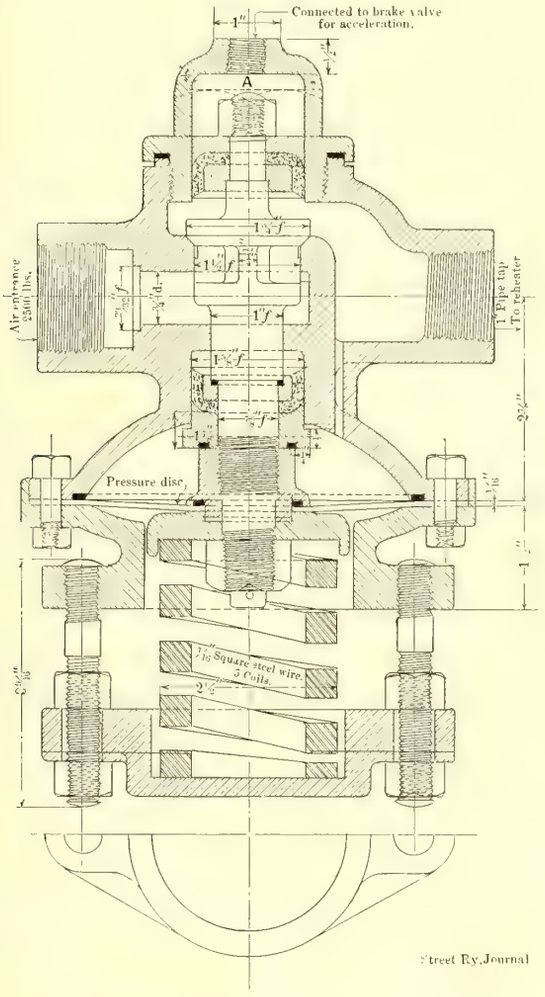


FIG. 2.—SECTION OF REDUCING VALVE

and the normal working pressure is now sufficient to close the valve against the spring and keep the motor in operation.

It will be noticed that the valve itself is connected by ribs or wings to a collar on the valve stem. This is done as a matter of safety. Should the valve stem break at any point under this collar, the entering high pressure would immediately open the valve, but the collar entering the seat prevents a dangerous rush of air into the working pressure reservoirs and pipes. It will also be noticed that the follower of the equalizing piston has a shoulder which will permit of 1-16 in. movement of the valve in ordinary working, so that the safety collar can never enter the seat unless the valve stem breaks.

After passing through the reducing valve, the air is at working pressure of 150 lbs., and is then led to the reheater, which is placed in the middle of the truck. This reheater contains about 500 lbs. of hot water, the temperature of which at the start is about 320 deg. F., but during a trip this temperature falls sometimes as low as 170 deg The air is passed into the bottom of this heater and escapes into the water through a perforated pipe lying along the bottom of the heater. When the reservoirs need to be recharged with air, and the car is run to the charging station for this purpose, steam is passed through this same perforated pipe to reheat the water.

During its passage through the water, the air is heated to the temperature of the water, and is then drawn off at the top through the perforated pipe *T*. The baffle plates shown are to prevent a swash of water caused by the car oscillation.

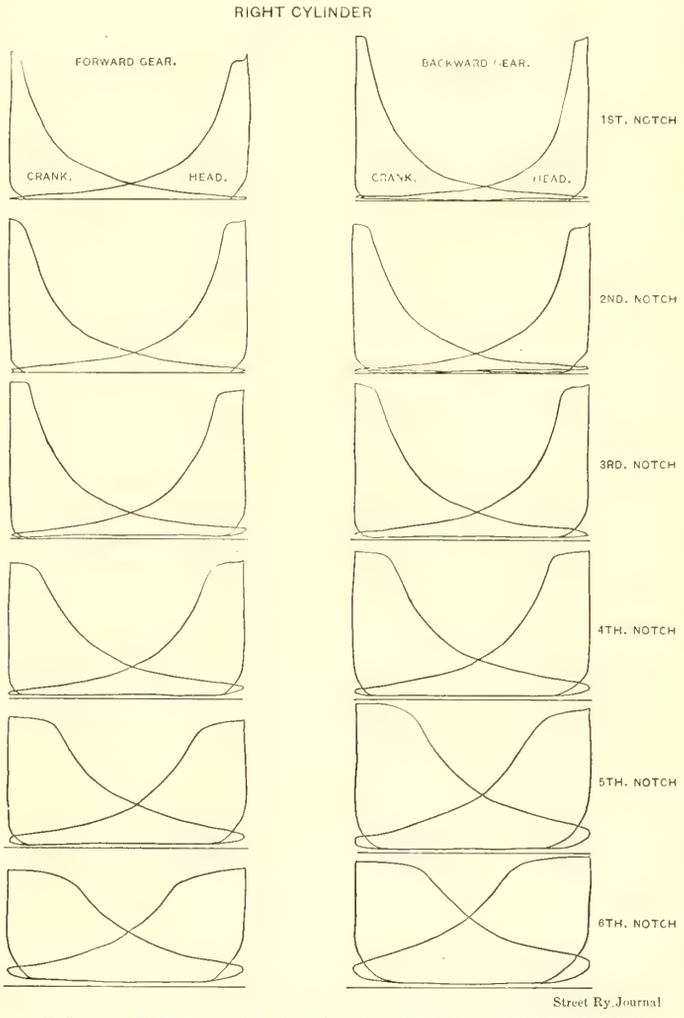

FIG. 3.—TYPICAL INDICATOR DIAGRAMS AT DIFFERENT NOTCHES

The efficiency of reheating is illustrated by the following test: A motor was run two trips, as far as possible each trip, on a full charge of air, first without heat and afterward with heat, covering 8 miles and 15 miles respectively; showing that the additional 7 miles were obtained from the heat, and careful measurements showed that the amount of heat used was 98,000 heat units. In ordinary practise, from 10 to 12 lbs. of coal will supply this amount of heat to generate steam in steam boilers. As this amount of steam injected into the water in the heater will restore the 98,000 heat units, it follows that the additional 7 miles were obtained on an equivalent of from 10 to 12 lbs. of coal.

Returning now to the cycle of operations, the air, which is now at about 150 lbs. pressure, and at a temperature of about 320 deg. F., passes from the perforated exit pipe *T* to the throttle valve of the motor, and thence to the valve chest of the engine in exactly the same way as steam in a steam engine.

The valve chest of the engine cylinders contains two valves, one the distribution or main valve, and the other the cut-off valve. These valves are operated in such a man-

ner that any degree of cut-off can be obtained, as illustrated by the indicator diagrams. Compressed air has this advantage over steam, that it does not condense during expansion in the engine cylinder. Therefore, expansion may be carried with economy clear down to atmospheric pressure. To do this in a steam engine would cause what is

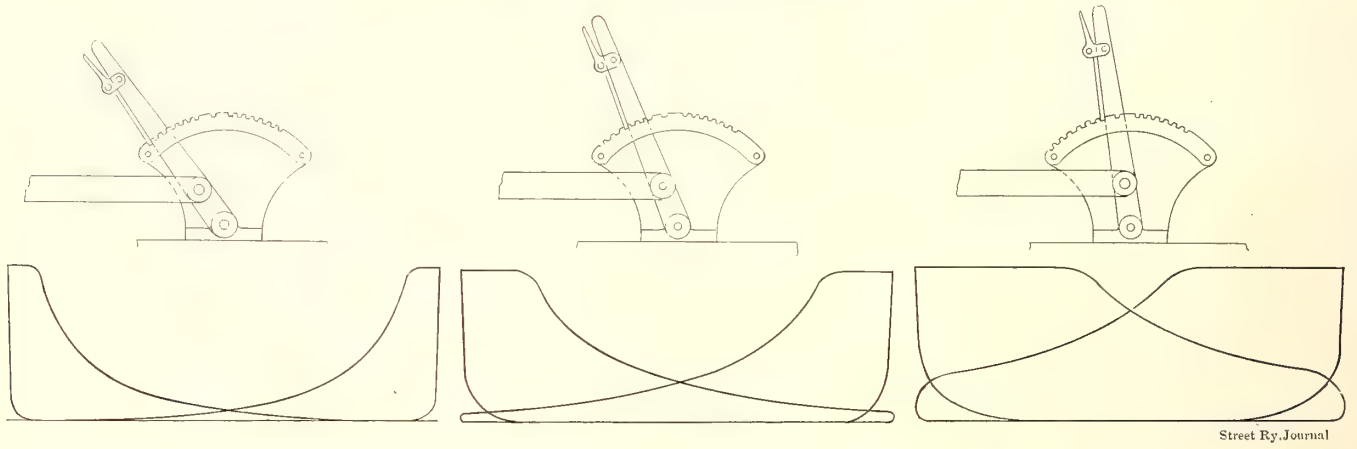
* Cut-off at 47 deg. Average piston travel, 1.91 in.



Main cut-off and compression crank angle, 148 deg.
Lead angle of crank—front, 12 deg.; back, 12 deg.
Point of cut-off, not including clearance, $\frac{1}{14.81}$ of stroke
Point of cut-off, including clearance, $\frac{1}{9.54}$ of stroke
Greatest port opening, 7-16 in.
Relative travel of main and cut-off valves, 3⅝ in.

Main cut-off and compression crank angle, 138 deg.
Lead angle of crank—front, 13 deg.; back, 13 deg.
Point of cut-off, not including clearance, $\frac{1}{6.29}$ of stroke
Point of cut-off, including clearance, $\frac{1}{5.19}$ of stroke
Greatest port opening, ⅜ in.
Relative travel of main and cut-off valves, 2 11-16 in.

Main cut-off and compression crank angle, 117 deg.
Lead angle of crank—front, 18 deg.; back, 18 deg.
Point of cut-off, not including clearance, $\frac{1}{2.42}$ of stroke
Point of cut-off, including clearance, $\frac{1}{2.29}$ of stroke
Greatest port opening, 9-32 in.
Relative travel of main and cut-off valves, 1⅝ in.

The variation of cut-off is effected by changing position of reverse lever (see above sketches), and grades of cut-off are obtainable between those given in the tables, the earliest grades being when lever is full over, so as to give valve full throw. In this position there is also the greatest amount of lead. Cut-off, including clearance, means piston travel at cut-off + clearance / stroke of piston + clearance; clearance in cylinder, 4 per cent.

Inside and outside lap being equal, main valve cut-off and compression take place at the same point.

The greatest port openings noted above are taken at the point where cut-off and main valve openings are equal, the cut-off closing while the main valve is opening. In the earlier grades this takes place near beginning of stroke when piston is moving slowly, and in the later grades when motor is moving slowly. There is always ample exhaust opening.

Readings were taken at equal crank angles for convenience, but valves would be set to cut-off at equal piston movements from each end of cyl.

known as cylinder condensation. Steam engines are compounded principally to reduce this cylinder condensation to a minimum, but this is not necessary with compressed air.

It was necessary to contrive a valve mechanism which would not be too complicated to operate, and yet obtain the best results. The valve mechanism which is attached to these motors is illustrated in Fig. 4. The usual Stephenson link motion is used to operate the main valve, but on the outside of the link there is an arm *a*, looking down as well as up. At the lower end of the lower arm is attached the lower end of a floating lever, *f*. The upper end of lever *f* receives a reduced motion, which is the opposite of the piston, through the lever *g* and link *l*, lever *g* being pivoted by a bracket attached to the frame at the point *p*. It will be observed that the lower end of floating lever *f* receives a motion directly the opposite of the main valve, and that its upper end has a motion directly the opposite of the piston rod. This lever *g* is attached to the cut-off rod at the point *m*, and gives to the cut-off valve a motion which is the resultant of the other two. The consequence is that when the main valve is traveling in full gear, the cut-off valve is also traveling at its longest stroke, and gives the earliest cut-off. When, however, the link motion is "cut back" so as to reduce the motion of the main valve, it gives a later cut-off. The indicator cards, shown in Fig. 3, indicate the effect of this. The first notch indicates the full travel of both valves, and each succeeding notch a reduced travel of both valves, showing a later cut-off. It will be observed that the latter grades show some terminal pressure which produces an audible exhaust, but these grades of cut-off are used only for starting the motor, and the lever is immediately moved to a position corresponding with either of the first three notches, according to the power required, which depends upon the loads and grades. It will be observed while cutting off at the earlier notches there is a freer exhaust, which will more readily free the cylinder when going fast. In the ordinary locomotive the cutting off is effected by the link motion only, with the result that the exhaust openings are diminished.

It will also be observed that the various grades of cut-off within the control of the motorman are effected by the same lever which reverses the motion, thus simplifying the operation of the motor very materially, and bringing it within the comprehension of the average street railway employee.

The weight of the entire equipment is said to be practically the same as an electric equipment, and all parts are flexibly supported on the axle box by means of four semi-elliptical springs, after the most modern locomotive practise. This support is entirely separate from that of the car bodies, which are carried on a different set of springs resting on the frame of the truck. In this use of flexible suspension, the system differs radically from the former air motors used on the Twenty-Eighth and Twenty-Ninth Streets line, where the case carrying the motors rested directly on the axles.

There remains now only one portion of the equipment to be described, *i. e.*, the air brakes. The air brake cylinder is illustrated in section in Fig. 6. In applying the brakes air is admitted to the annular space *R*, around the hollow piston rod, and to release the same air is made to pass to the other side of the piston from *T* around through *V*, thus equalizing on both sides of the piston. Having a larger area to act upon on the other end, the brake is released at once, the air escaping silently through the small opening

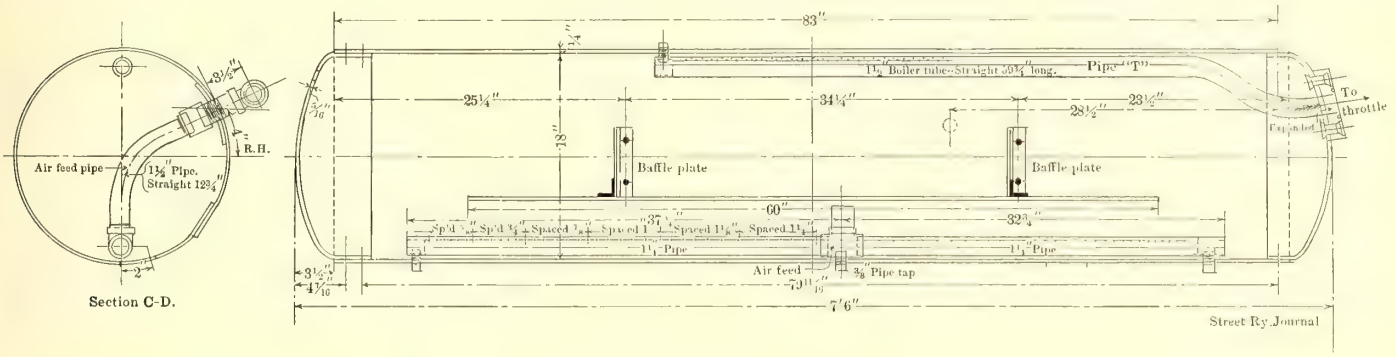


FIG. 5.—SECTIONS OF REHEATER

S, and out to the atmosphere through the openings at *W*, at the end of the plunger.

The Twenty-Eighth and Twenty-Ninth Street railway is now being operated by horses pending the change from the Hoadley-Knight to the Hardie motors. There is every reason to expect that these new motors will be successful, because Mr. Hardie has had more experience in this line than any other engineer in the United States, and has made the subject a special study for years. He has, moreover,

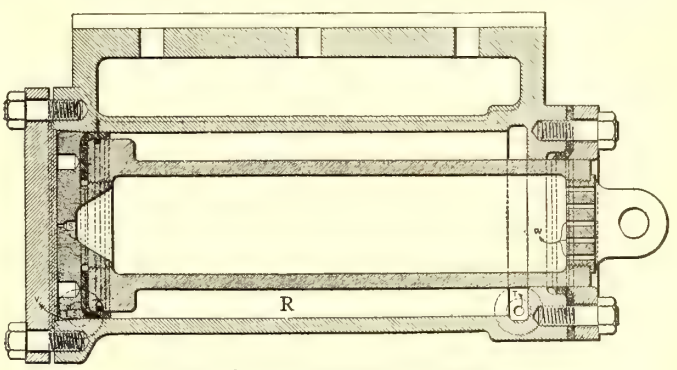

FIG. 6.—AIR BRAKE CYLINDER

held many responsible positions, and stands high in the profession. His standing among engineers is well expressed in the following extract from *Compressed Air*: "His mechanical ideas are marked by much individuality, the elements of simplicity being prominent. It is doubtful if any one has had as much experience as Mr. Hardie in pneumatic traction, and he is the acknowledged authority on the subject."

The work of transforming the Lexington Avenue line in New York from a cable to an underground trolley road is completed between 105th Street and Twenty-third Street. The final change from cable to trolley, however, is not to be made until the work is finished in Broadway, as the managers of the Metropolitan Street Railway Company believe the patrons of the road would not relish a change at Twenty-third Street from the trolley cars to the cable car in Broadway. The Columbus Avenue line is now being changed, and President Vreeland believes that both the east and west side cable lines and the Broadway line above Twenty-third Street will be finished by Nov. 1.

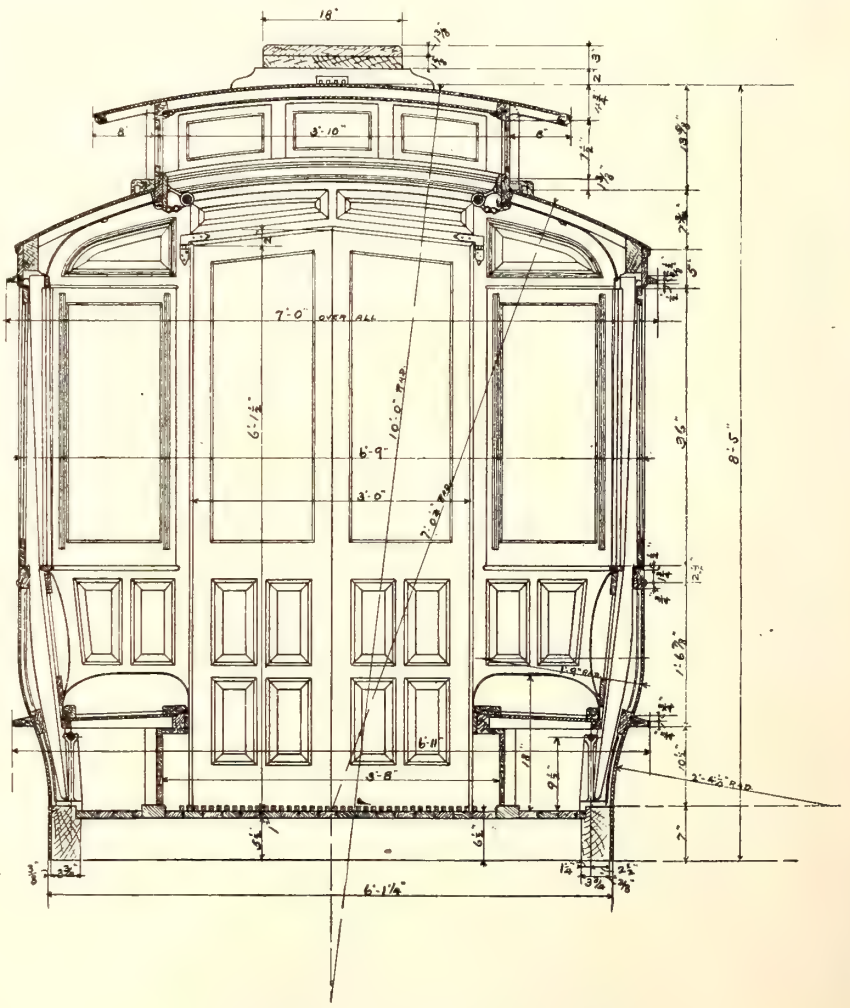
The Electric Railways of Havana

The city of Havana is located upon a peninsula and is very densely populated. The unhealthy condition of the city is, to a considerable extent, due to this dense population. There is a good chance for development of the suburbs in various directions, and as soon as a good system of rapid transit is provided these suburbs will grow rapidly. In the immediate vicinity of Havana are some very fine suburbs, particularly Carmelo and Vedado. This quarter is located upon the seashore a few miles from the city, and is now inhabited by the wealthier classes and by foreigners. It is now considered the healthiest location in the vicinity of Havana. Beyond this about 4 miles is a very fine beach, Maraino. The census of 1887 showed the population to be about 250,000. There was considerable increase since that date up to the time of the last war, when the population naturally fell off, and it is estimated that at present the population is about 275,000. It is estimated that the population in 1905 will be about 400,000. Up to the time of the organization of the Havana Electric Railway Company the street railway system, Ferro Carrill Urbano, consisted of about 25 miles of track located upon 13 miles of streets. Considering the size of the city, this amount of mileage was totally inadequate for the proper accommodation of the public, and, based on the experience in American cities, could be increased to three or four times the amount with advantage. The "Ferro" operated sixty-one cars and eleven steam engines. The number of passengers carried on the street railway lines before the war reached about 7,500,000 per year, even at the high rates of fare of 15 cents, 10 cents and 5 cents, which were charged on many of the lines. The Havana Electric Railway Company, which has taken over the property of the "Ferro" Company, has now in course of construction about 80 miles of track, and proposes to operate about 120 cars.

Before construction could be commenced it was necessary to submit to the Governor of Havana plans showing routes and details of construction, as well as specifications, plans and estimates for equipping the lines with electric motive power. The requirements of the Department of Havana were that the electrical system to be provided must be safe, rapid, elastic as to speed, comfortable, clean, convenient, flexible enough to serve all routes and sections of the city and suburbs, and cheap to operate and maintain. This would enable the dense population of Havana to spread out and live in a more healthful manner.

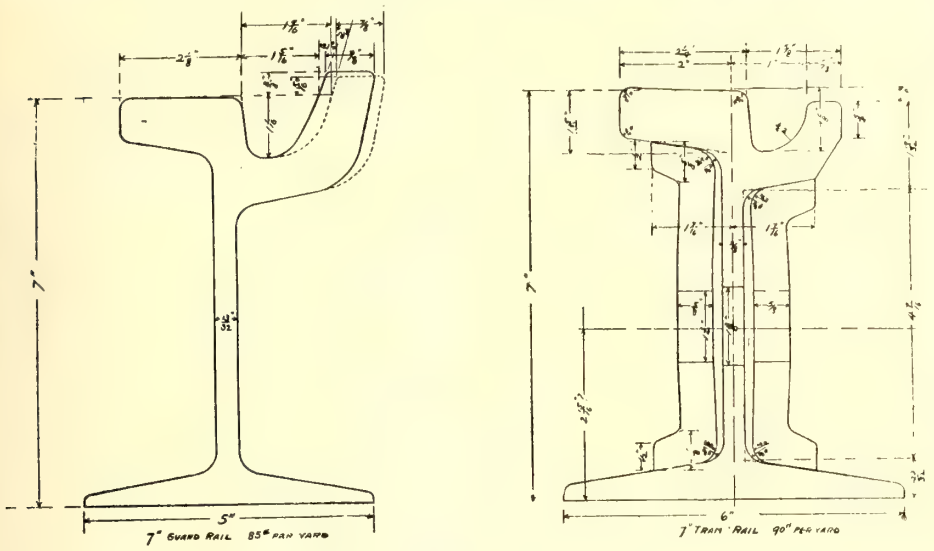
VIEW OF FERRY TO REGLA, OWNED BY THE CUBAN ELECTRIC CO.

Owing to the narrow streets in part of the city it was deemed proper to fix upon two maximum rates of speed on narrow streets, the average speed to be 6 miles per hour and maximum 8.5 miles per hour, and on wide streets the



SECTION OF STANDARD CAR, HAVANA

average speed to be 8.5 miles per hour and maximum 14 miles per hour. On each route cars will be run on a varying schedule to suit the requirements of travel, starting with ten-minute headway, reducing the headway to 7½ minutes and then to 5 minutes, so that during six hours daily the headway on each of the four lines will be 2½ minutes. Night-car service will be established from midnight until regular day-car service.



SECTIONS OF STANDARD RAILS

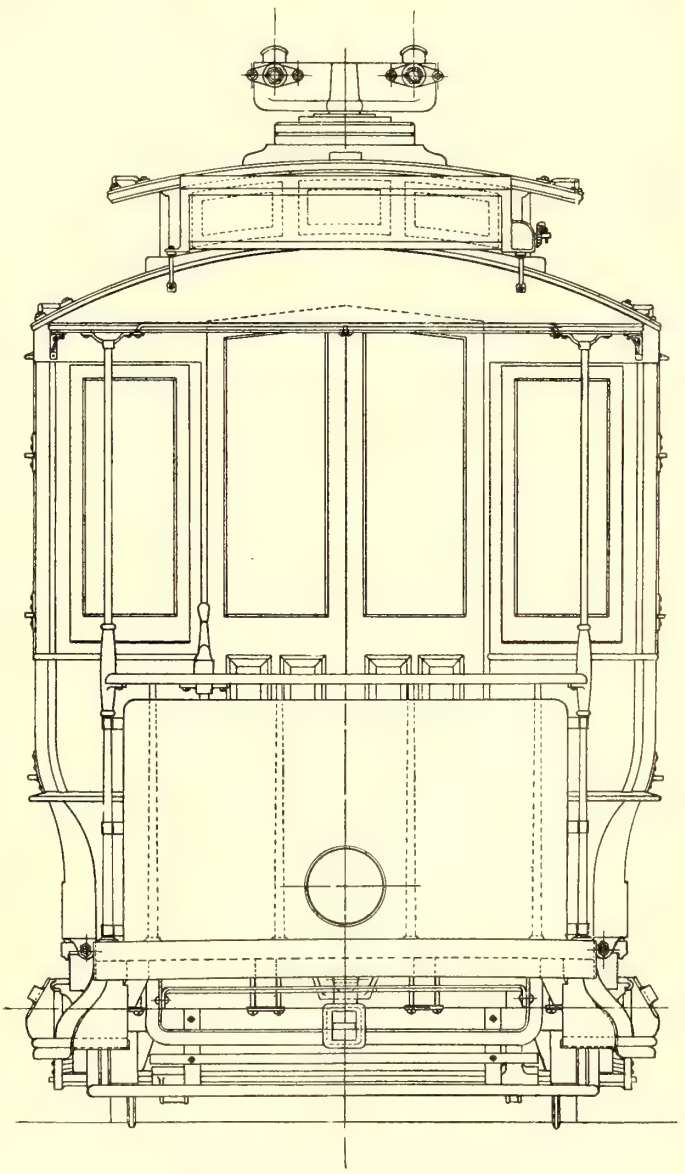
The cars, which are being made by the Jackson & Sharp Company, will have a seating capacity of twenty-six passengers and a maximum load of forty-five passengers. There are 120 of these cars, each being equipped with two Parmenter fenders. The cuts give a good idea of their construction.

The general dimensions of the car bodies are as follows: Length over all, 29 ft. 6½ ins.; length of body, 20 ft.; width of body over all, 7 ft.; height of body, 8 ft. 5 ins.; track gage, 4 ft. 8½ ins.; diameter of wheels, 30 ins.; wheel base, 7 ft.; type of truck, McGuire, A-1 suspension. Each motor car to be equipped with two General Electric 52 motors, capable of developing continuously for one hour 25 hp each without increasing the temperature of the motor windings more than 75 degs. C., and when so working to have not less than 77 per cent efficiency. If found necessary, freight cars will be placed on the lines to carry freight and express packages.

The track construction consists of 7-in. girder-rail, weighing 90 lbs. per yard, laid on concrete stringers, with standard soft steel ties 5 ft. 9 ins. in length and 7 ins. wide. The rail is fastened to the ties by clips or chairs, as shown in the illustration. The special track work will be of a design known as Adamantine construction. The rails, ties, etc., are being supplied by the Pennsylvania Steel Company. Between the rails and to a distance of 22 ins. outside the paving will consist of pyrogranite, asphalt and Macavoy brick. Beyond that limit the ordinary macadam will be used on the roadway.

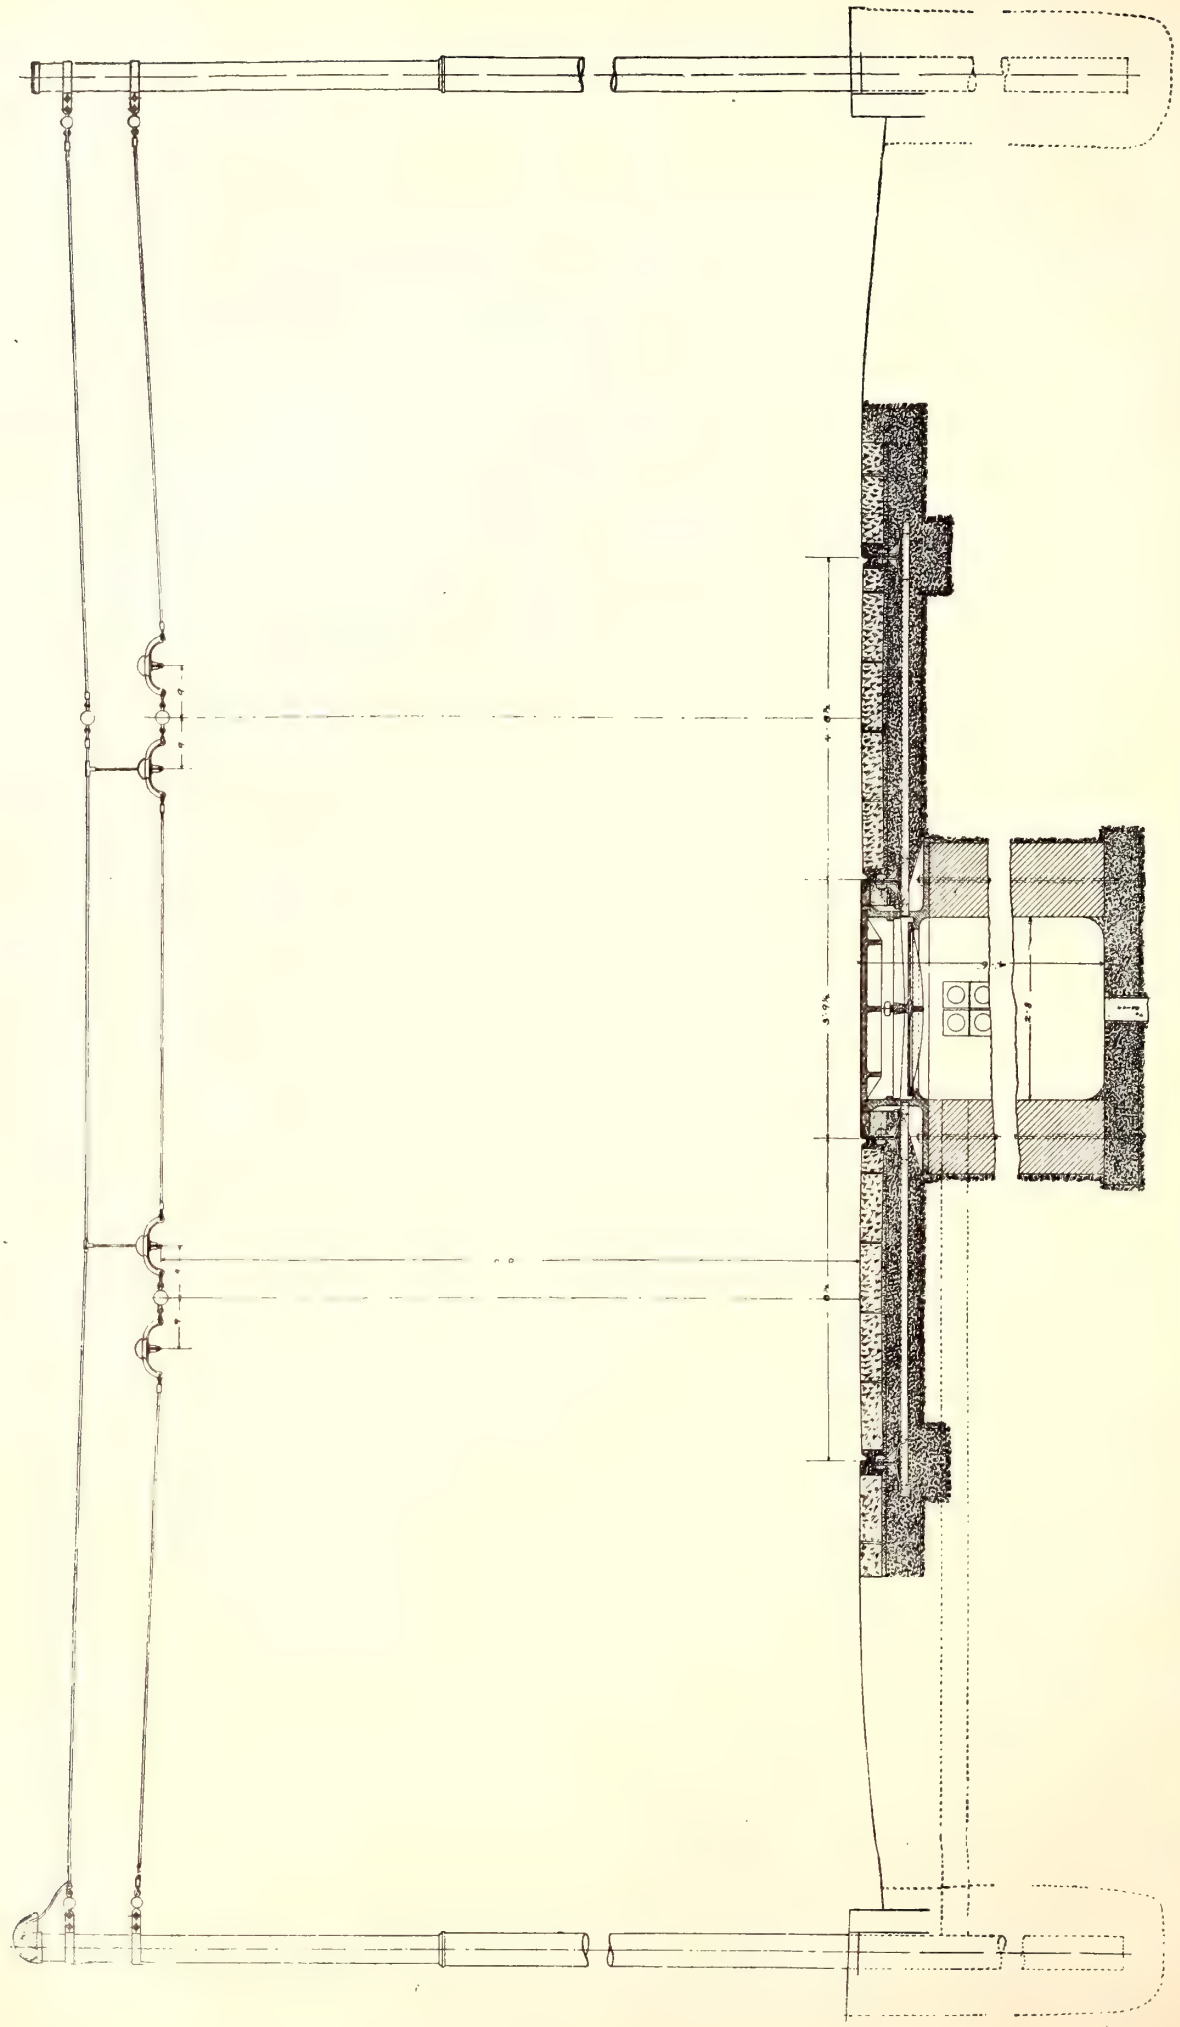
Most of the poles for the overhead construction are made of heavy iron pipe in two sections, the lower section being 6 ins. in diameter and the top section 5 ins. in diameter. The lower section is shrunk onto the top section, the poles when finished being 26 ft. over all. On narrow streets the overhead wire will be supported from hangers attached to the buildings, or the construction shown in the accompanying drawing will be used. All poles are to be set 6 ft. in the ground in concrete, the holes for receiving the poles being not less than 24 ins. in diameter. The span wire to be used is No. 7 galvanized iron wire. The Havana authorities have insisted that the double overhead trolley system be installed. The two trolley wires erected over each track, one for each side of the circuit, are 18 ins. center to center, the trolley wire being of hard drawn copper wire .325 ins. in diameter. The trolley wires are supported from the span wire by double curve insulators composed of a malleable iron body, screw cap and cone insulators and bronze ear, the ears being securely soldered to the trolley wire. The poles are being supplied by the Electric Railway Equipment Company, and the overhead material by the A. & J. M. Anderson Manufacturing Company. All feeder wires will be laid beneath the surface of roadway in ducts made of Potomac terra cotta. The feeders consist of 1,000,000-circ. mil and 500,000-circ. mil cables. All feeders were supplied by W. R. Brixey.

The power-station equipment consists of three vertical cross compound condensing engines with 48-in. stroke, high-pressure cylinder 23 ins. in diameter, low-pressure cylinder 60 ins. in diameter. The



END ELEVATION OF STANDARD CAR

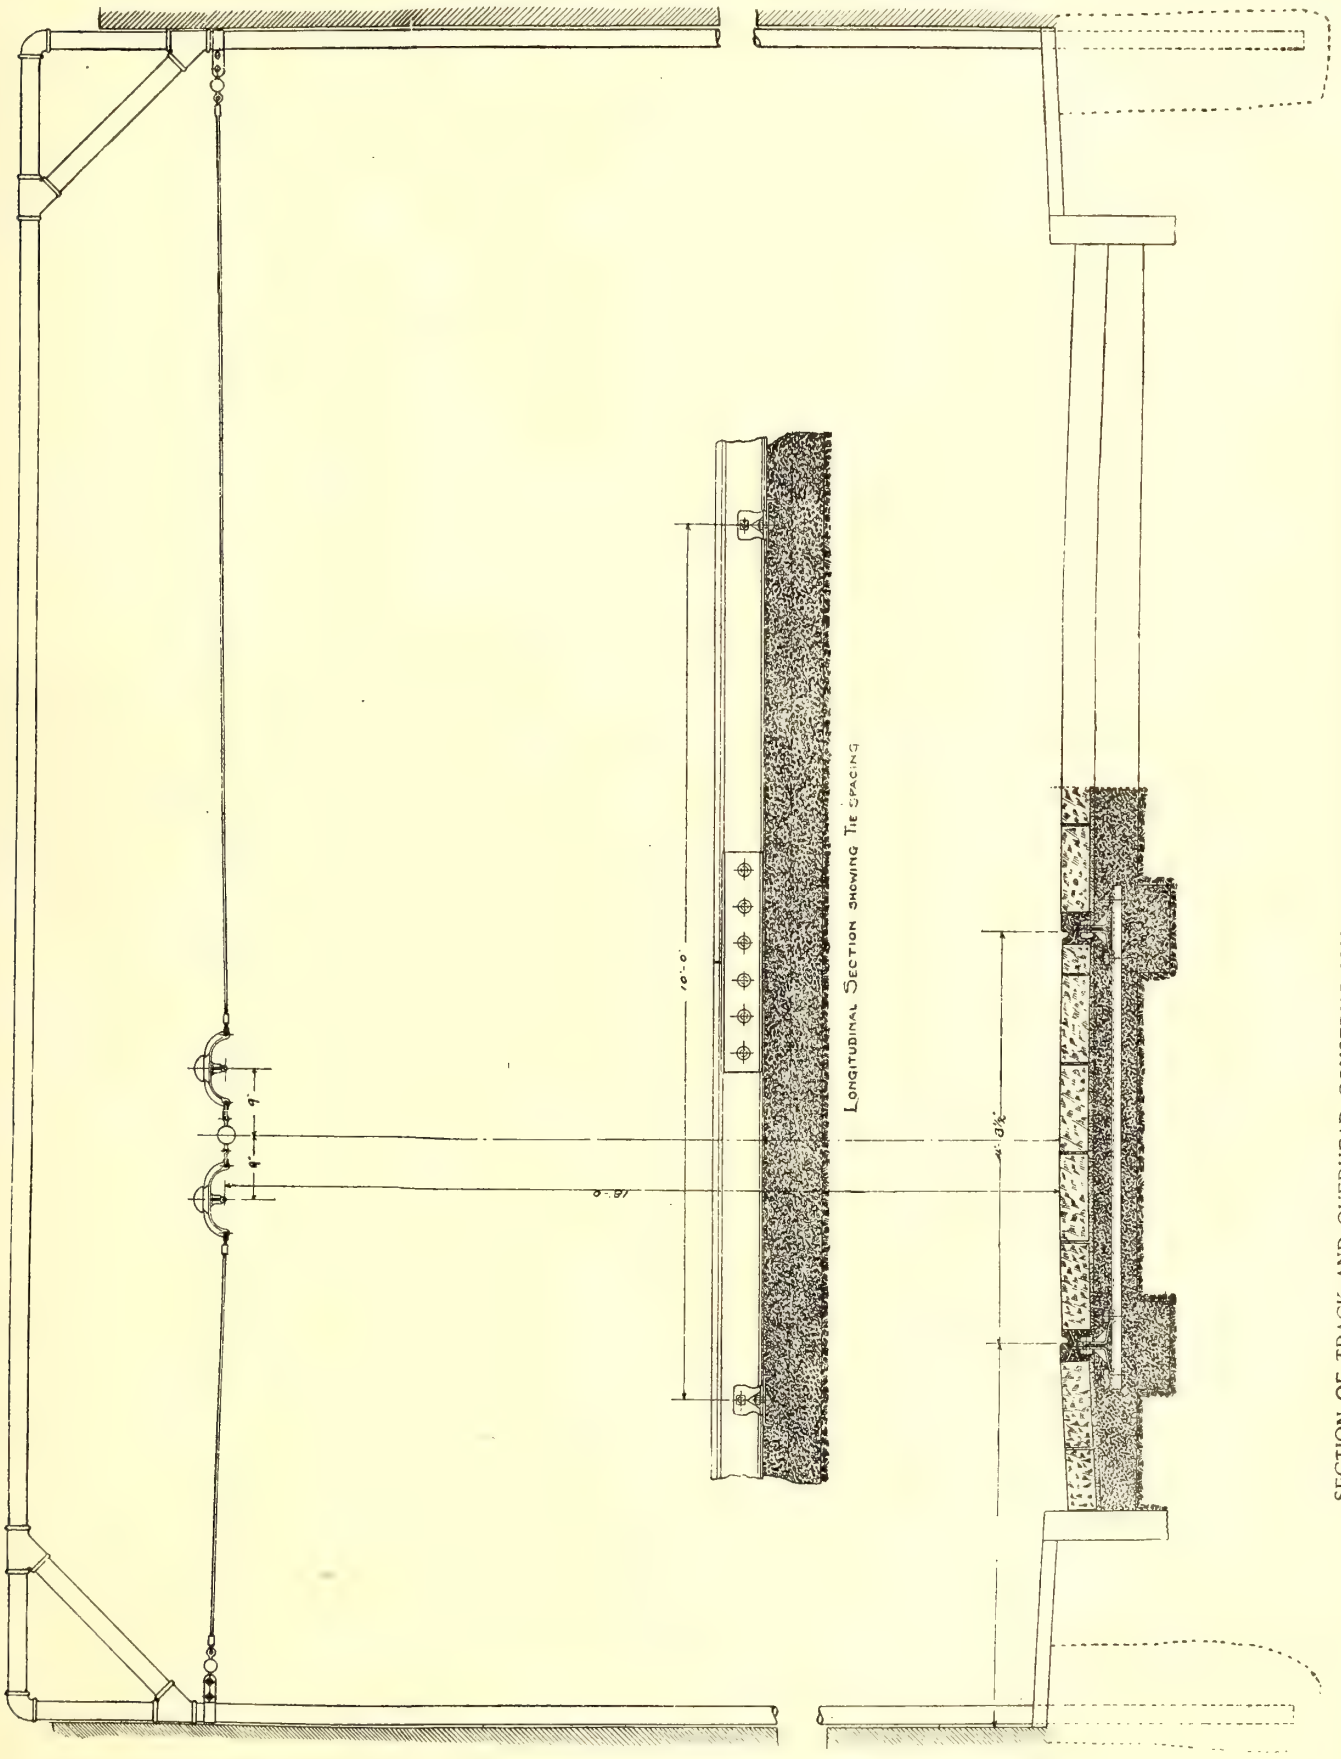
engines are of the E. P. Allis make, and are to be operated at 80 r. p. m., with 125 lbs. steam pressure. The



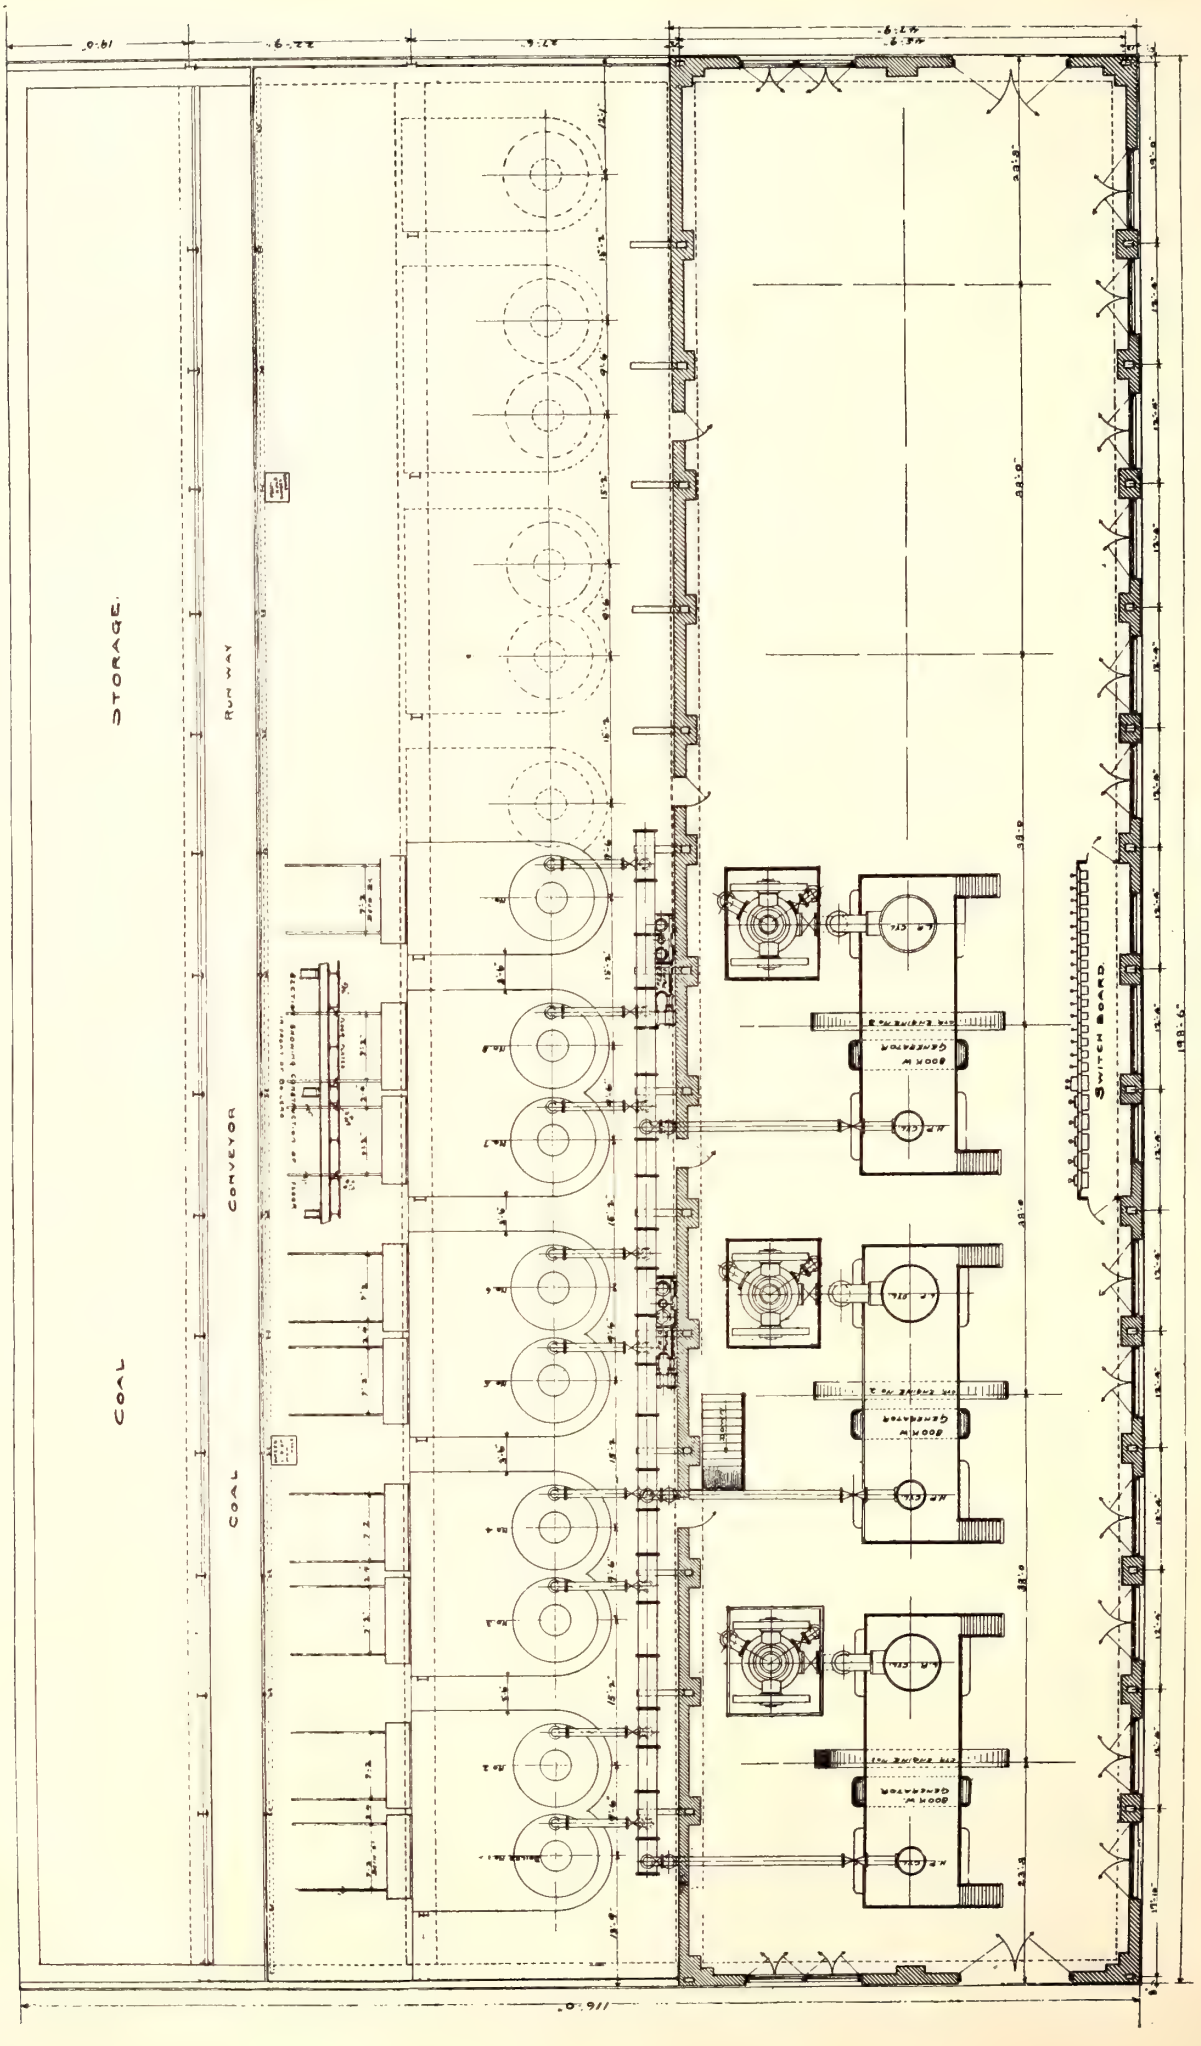
SECTION OF TRACK AND OVERHEAD CONSTRUCTION IN BROAD STREETS, SHOWING DOUBLE OVERHEAD WIRES AND UNDERGROUND FEEDER CONDUITS

boiler plant consists of nine vertical water-tube boilers of 250 hp each, set in three batteries. The boilers are of the Cahall vertical type.

The electrical equipment consists of three 850-kw generators of the General Electric Company's manufacture, voltage being 550, complete switchboards and accessories being furnished. A 50-kw Triumph dynamo is also included for lighting purposes. The power house building will be of steel construction, 198 ft. 6 ins. long by 96 ft. 6 ins. wide with a span in engine room of 45 ft. and a span over boilers of 51 ft. The walls of the building are to be of brick laid in lime mortar. The interior wall will be laid with enamel brick for a wainscot 6 ft. in height. The engine-room roof will be constructed of concrete laid on and between the steel purlins and covered with tile laid in cement. The roof over the boiler room is to be constructed of corrugated



SECTION OF TRACK AND OVERHEAD CONSTRUCTION IN NARROW STREETS, SHOWING OVERHEAD PIPE BRACE

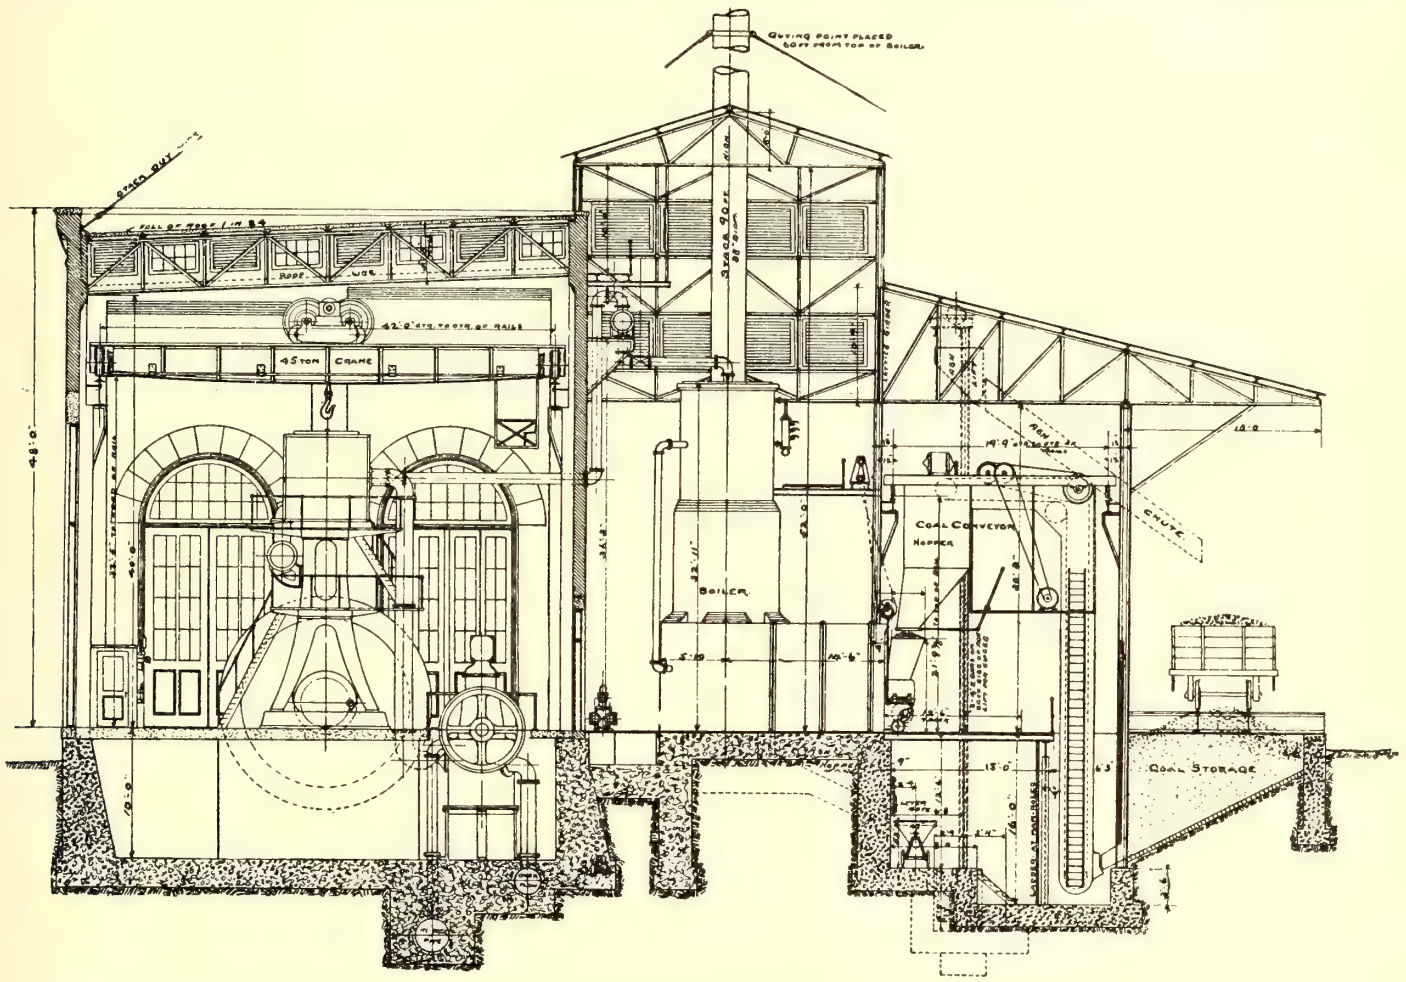


PLAN OF POWER STATION, HAVANA

iron securely fastened to the steel purlins. It is proposed to make the fare 5 cents, United States currency, anywhere in Havana. Transfer tickets will be given at intersecting points. The lines immediately within the city are expected to be in operation by Dec. 1, 1900. The Havana syndicate consists of Thomas F. Ryan, of New York; W. L. Elkins and P. A. B. Widener, of Philadelphia; A. Marcus, of New York, representing the French and English interests; Sir William Van Horne, Hanson Brothers, bankers; W. M. Doull and Frederic Nicholas, all of Montreal; William Mackenzie, of Toronto; A. H. Paget, Col. G. B. M. Harvey, F. S. Pearson, Percival Farquhar, of New York. G. F. Greenwood, formerly of Pittsburgh, is chief engineer and general manager. Owing to the many arduous conditions, the engineering work involved required unusual study and ability, and the successful results already shown are a tribute to Mr. Greenwood's skill and foresight.

Across the harbor from Havana and connected with it by ferry is the town of Regla. On March 10 last the first Cuban electric railway was opened, between this town and that of Guanabacoa, 4 miles inland. This line is part of the former Le Prueda Railroad Company's system, which was the first railway in Cuba to be operated by steam power, and is likewise the first to adopt electricity for its motive power. Originally, in 1858, the company was inaugurated for transit across the bay, and was known as the Primera Empresa de Vapores de la Bahia movidos porfuerza animal. Since then the town of Regla has developed into a suburb of 10,000 people, and the town of Guanabacoa has 20,000 inhabitants, and both contribute most of their working population to the main city of Havana, so as to require not only ample, but prompt, transit between the two points most of the day. With the electric cars and boats from the Lux wharf, this demand is now supplied in the most modern fashion.

The Cuban Electric Company bought the road on Jan. 16, 1899, and at once began the work of change of motive power. The company is organized under the laws of New Jersey with the following officers: President, Hon. A. F. Gault, of Montreal; directors, W. M. Doull and Wm. Hanson, Montreal; B. F. Pearson, Halifax, N. S.; F. S. Pearson and Col. G. B. M. Harvey, New York; general manager, A. C. Goudie. The company operates two ferry boats between the city of Havana and the town of Regla.



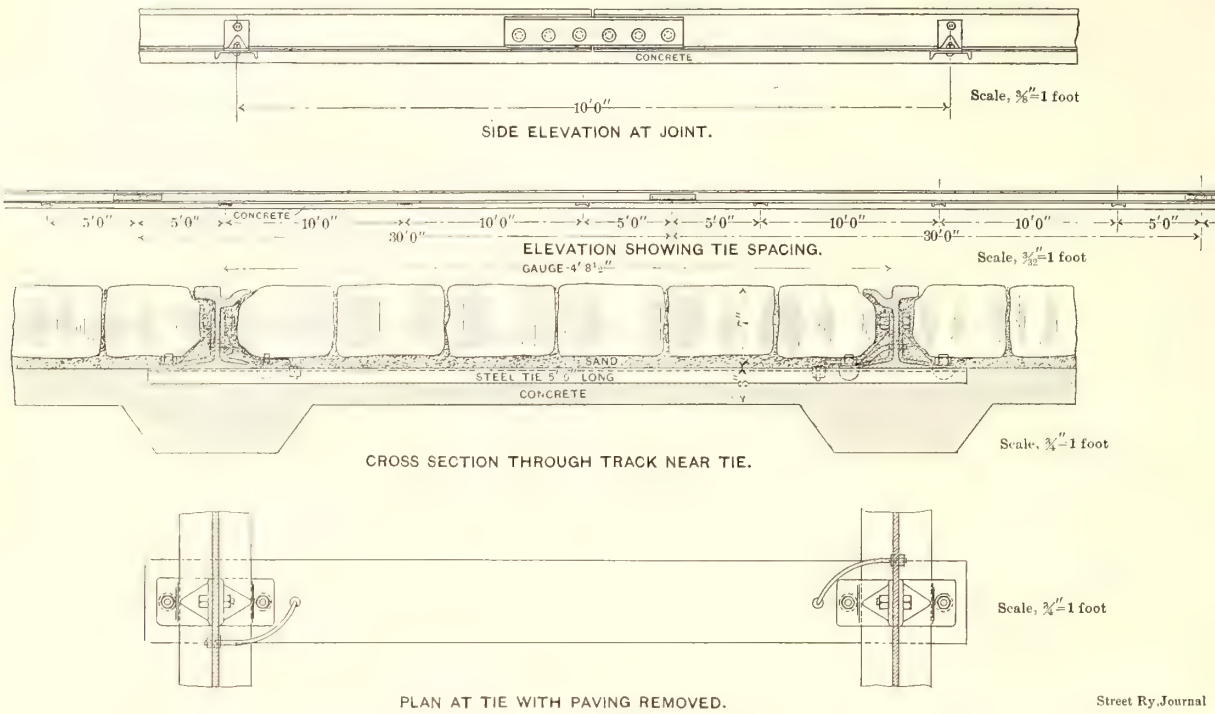
CROSS SECTION

SECTION OF POWER STATION, HAVANA

The trolley line begins at the ferry landing in Regla, and, after a winding course through the town and over private right of way, leads out into the open country through abandoned farm lands, where cool sea breezes greet the passengers. In the near future it is proposed to extend the line to the town of Cojimar, about 1 mile beyond Guanabacoa. In Guanabacoa the company is now constructing a pleasure park, where concerts and entertainments will be held and refreshments served. Later it is proposed to install an electric fountain. Besides the income from the transportation of passengers, the receipts from the passage of vehicles on the ferry line are considerable. Ample provision is made for their accommodation in the ferry houses. The present terminal at Regla is soon to be replaced by a modern steel frame building and proper facilities for handling the traffic. The electric cars are to run in between platforms which lead directly to the ticket booths and waiting rooms.

The track construction consists of both girder and T-rail.

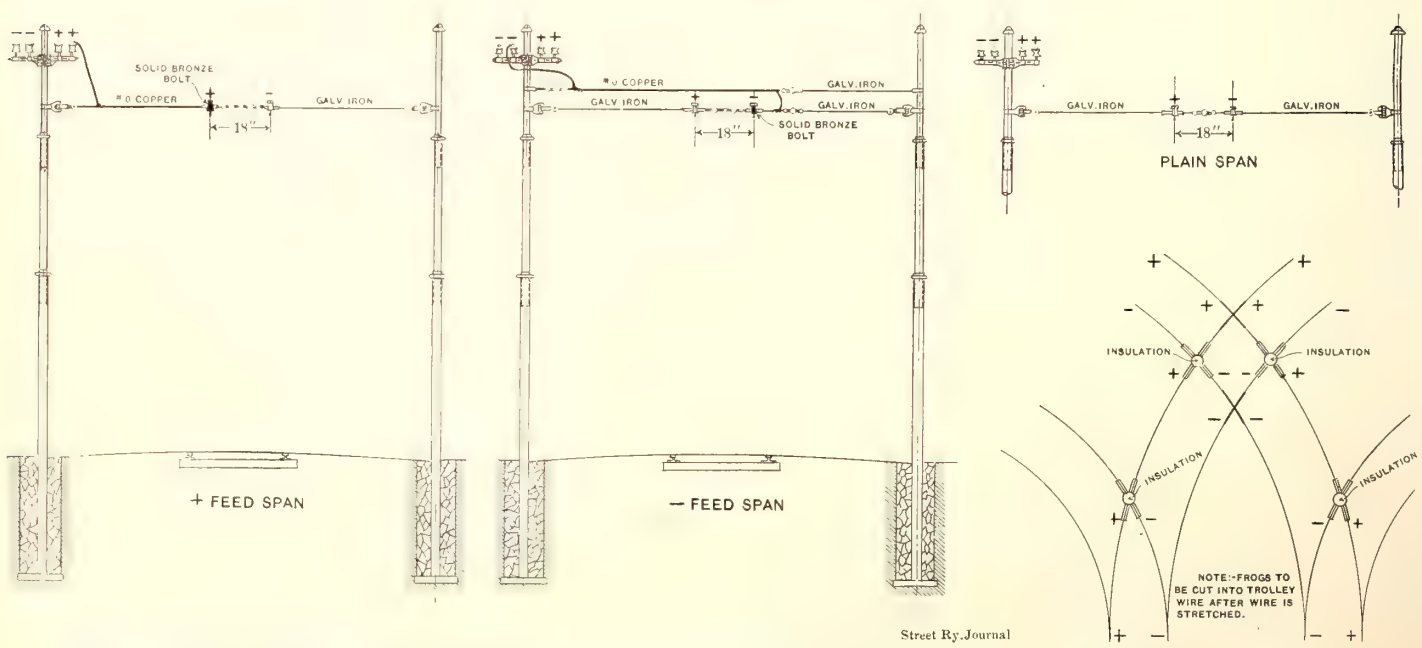
The girder-rail used is the Pennsylvania Steel Company's section No. 272, weighing 62 lbs. to the yard, and is laid on and securely bolted to steel cross-ties spaced 10 ft. apart on a longitudinal bed of concrete. The T-rail is of the Pennsylvania Steel Company's section No. 243, weighing wire. For a portion of the road the trolley wires are supported by single-pole brackets, but in general the span wire suspension is used. The maximum distance between poles is set at 125 ft. The feeders are of 500,000-circ. mil cable, and in Guanabacoa 00 grooved trolley wire is used. Light-



PLAN AND SECTION OF TRACK CONSTRUCTION, CUBAN ELECTRIC CO.

90 lbs. to the yard. The T-rails are laid on native hardwood ties 6 ft. x 6 ins. x 8 ins. spaced 2 ft. apart, on which they are securely spiked. The return circuit to the power station being by means of the trolley wire and overhead feeders, the track is not bonded. On account of local conditions the authorities, as in the city of Havana, com-

ning arresters for the protection of the line from lightning have been installed. The wire for the overhead construction was furnished by the American Steel & Wire Company, John A. Roebling Sons' Company and the General Electric Company. Line material, by the A. & J. M. Anderson Manufacturing Company.



VIEWS OF TROLLEY SPANS WITH PLUS AND MINUS FEEDER CONNECTIONS, AND PLAN OF DOUBLE TRACK Y, SHOWING LOCATION OF INSULATORS

pelled the company to install a double overhead trolley system. The construction is much like that described above, except that overhead feeders are used. The illustrations show the peculiar precautions which must be taken with the double trolley construction at turnouts and where the positive or negative feeder is connected to its respective

The rolling stock consists of four 28-ft. vestibuled cars of the J. G. Brill Company's make, mounted on Eureka maximum traction trucks. The old cars of the company are used as trailers. The seats of the new cars are upholstered in cane and arranged transversely with an aisle through the center, having a seating capacity of forty pas-

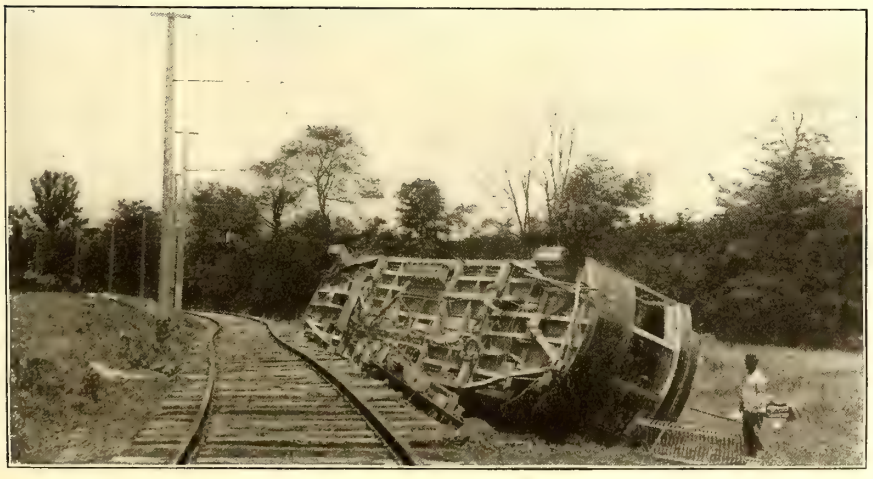
sengers. The cars are equipped with the West End type of fender. The motor equipment consists of two Westinghouse No. 38-B, 50-hp motors.

The power-station equipment consists of two horizontal tandem compound condensing side-crank engines made by the Robb Engineering Company, Amherst, N. S., directly connected to two Westinghouse 150-kw generators, the voltage at full load being 550 volts. The entire electric equipment of the power station was furnished by the Westinghouse Company. The steam, exhaust and water piping, with valves and fittings, were furnished by the Robb Engineering Company. The boiler equipment consists of one battery, 400 hp, of Cahall vertical boilers furnished through Thayer & Company. The power-station building is of steel construction, and was furnished by the Ritter-Conley Company. Two iron tanks are used, having a capacity of 10,000 gals., for the purpose of supplying the water for condensing purposes, these tanks being connected to the roofs of the buildings by drips, so as to catch the rainwater.

STANDARD 28-FT. MOTOR CAR, CUBAN ELECTRIC CO.

An Accident on the Cincinnati, Lawrenceburg & Aurora Street Railway

The accompanying illustration shows an accident which took place on July 4 on the Cincinnati, Lawrenceburg & Aurora Street Railway, caused by the breaking of a flange on the outside front wheel of the rear truck. The piece of the flange broken out was 12½ ins. long, and was broken off at a point 3 miles from where the accident occurred.



ACCIDENT NEAR AURORA

The car was running 20 miles per hour on a 1000-ft. curve, when it left the rails. The motorman applied the brakes, and stopped the car after it ran 150 ft. on the ties. The car had come to a stop before it turned over, and although there were thirty-four people aboard no one was seriously hurt, except a boy who jumped from the rear platform just as the car turned over; he was caught under the corner post and killed.

The irregular bend in the track, as shown in the engraving, was caused by throwing over the track after the accident occurred, in order to clear the line. The car itself was but slightly injured.

The accompanying illustration was furnished by J. B. Crankshaw, engineer of the road.

Street Car Building

(Stephenson Practice.)

BY CHARLES HENRY DAVIS, C. E.

VII.—Assembling—(Continued)

In the July issue of the STREET RAILWAY JOURNAL we gave the details of the bodies for our two standard cars, namely, the Boston (closed) and the Brooklyn (open). Tables Nos. 35 and 36 give respectively the details of roofs for the standard cars, while Plates VII. and VIII. illustrate the various parts. As in tables Nos. 31, 32, 33 and 34, each distinct part of the roof is described, giving the material, the general dimensions, how made, on what tools and how assembled, all in consecutive order as each car is built in the shop. In using these tables they are to be read across the page, line by line, as in the case of any book. In Column 1 the numerals indicate, in consecutive order, the number of distinctive pieces; where a letter follows the numeral it indicates another operation, but not another distinctive piece. Letters in Column 4 are the same abbreviations of wood work and metal work as used on Plates I. and II. These tables are given on the following pages.

TABLE NO. 35

DETAIL OF ROOFS AND BONNETS OF BOSTON CLOSED CAR, IN THE ORDER OF ASSEMBLING

(25 ft. Body; Car No. 2; Fig. 3; Plates I. and VII.)

Consecutive Number	Quantity	Name of Piece	Piece Number Plates I. and VII.	Material See Plates I. and II.	Details: Quantity	Details: Name	Reference Letter Plate VII.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
									During the erection of the sides and ends of the body (*see Table No. 33 and Plate V.*), the assembling of the pieces composing the framework of the "Moniter" roof has been proceeded with independently as follows:—	
104	2	**Ventilator plain-bottom-rails** (Figs. 197, 198)	2002	A.	..	.....	..	25 ft. 0 in. x 4½ in. x 1⅝ in.	Each having:—	
					2	Mortises		1¼ in. x ½ in. x 4 in	Not seen, one at each end, for ventilator side-corner-posts (2003) to tenon into, with two holes for dowel-pins	Hollow chisel mortiser
					8	Mortises	a	1⅝ in. x 1¼ in. x ½ in.	For ventilator side-posts (2005) to tenon into, with holes for dowel-pins	Hollow chisel mortiser
					8	Double Mortises	b	⅝ in. x ¾ in. x ½ in.	For rafters for lower-deck compound-carlines (2016) to tenon into	Hollow chisel mortiser
					27	Mortises	c	1⅛ in. x ¾ in. x ½ in.	For lower-deck rafters to tenon into (2015)	Hollow chisel mortiser
					1	Rabbet	d	full length x ⅞ in. x ⅜ in.	For ventilator side-sash (4001) to rest on	Molding machine
					1	Rabbet	e	full length x 1 in. x ⅝ in.	For roofing-boards (2014) and ventilator bottom-rail roof-molding (2027) to fit in	Molding machine
					2	Rabbets	f	full length x ½ in. x ⅛ in.	To fit the ventilator bottom-rail facia (4104)	Molding machine
									These rails are laid on horses, being prepared as above, and the following pieces are adjusted to them:—	
105	4	**Ventilator side-corner-posts** (Fig. 210)	2003	A.	..	.....	..	10⅛ in. x 4 in. x 1⅝ in.	Each having:	
					1	Tenon	a	4 in. x 1¼ in. x ½ in.	Tenoned into the end mortises of ventilator plain-bottom-rail (2002), glued and secured with two hickory dowel-pins each	End tenoner
					1	Tenon	b	4 in. x 1 in. x ½ in.	To tenon into end mortises (a) of ventilator top-rail (2001), Fig. 199	End tenoner
					2	Holes	c		For No. 14 x 2½ in. screws to secure the ventilator end-corner-posts (2004), Figs. 211, 212	Borer
					1	Bead	d		For inside ornament	Molding machine
106	16	**Ventilator side-posts** (Fig. 213)	2005	A.	..	.....	..	10⅛ in. x 1⅝ in. x 1¼ in.	Each having:—	
					1	Tenon	a	1¼ in. x ½ in.	Tenoned into mortises (a) of ventilator plain-bottom-rail (2002), glued and secured with hickory dowel-pins	End tenoner
					1	Tenon	b	1 in. x ½ in.	To tenon into mortises (f) of ventilator top-rail (2001), Fig. 199	End tenoner
					1	Bead	c		For inside ornament	Molding machine
					2	Ogees	d		For inside ornament	Chamfering machine
107	2	**Ventilator top-rails** (Fig. 199)	2001	Y. P.	..	.....	..	24 ft. 11¼ in. x 3 in. x 1⅝ in.	Each having:—	
					2	Mortises	a	4 in. x 1 in. x ⅝ in.	For ventilator side-corner-post tenons (b) to fit into; they are glued and secured with 4 No. 10 x ¾ in. steel screws	Hollow chisel mortiser
					2	Tenons	b	1 in. x 1 in.	To fit in rabbets (b) of the upper-deck head-rafters (2006), Fig. 205	End tenoner
					8	Gains	c	1½ in. x 1¼ in.	For upper-deck compound-carlines (2008), Fig. 196, to fit in	Multiple gainer
					27	Gains	d	1⅛ in. x 1¼ in.	For upper-deck rafters (2007), Fig. 217, to fit in	Multiple gainer
					1	Ogee	e		For inside ornament	Chamfering machine
					8	Mortises	f	1 in. x ½ in.	On under side, not seen, for ventilator side-post tenons (b) to fit into; they are glued and secured with 16 No. 10 x 1¼ in. steel screws	Hollow chisel mortiser
108	4	**Ventilator end-corner-posts** (Figs. 211, 212)	2004	A.	..	.....	..	10½ in. x 2⅜ in. x 1⅝ in.	Each having:—	
					1	Tenon	a	2 in. x 1¼ in. x ⅝ in.	To fit in rabbet (c) of the end top-rail (1006), Fig. 108, Plate V.	End tenoner
					1	Tenon	b	2⅜ in. x 1 in. x ½ in.	To fit in mortise (a) of the upper-deck head-rafter (2006), Fig. 205. They are also further secured to the ventilator side-corner-posts with 8 No. 14 x 2½ in. steel screws	End tenoner
					1	Rabbet	c	¾ in. x ⅜ in.	For ventilator end-sash (4007) to fit in	Molding machine
109	2	**Upper-deck head-rafters** (Figs. 204, 205)	2006	A.	..	.....	..	5 ft. 9¼ in. x 2 15-16 x 1⅝ in.	Each having:—	
					2	Mortises	a	2⅜ in. x 1 in. x ½ in.	For tenons (b) of the ventilator end-corner-posts to fit into; they are glued and secured with hickory dowel-pins	Hollow chisel mortiser
					2	Rabbets	b	1⅝ in. x 1 in. x 1 in.	For tenons (b) of the ventilator top-rails (2001) to fit in; they are secured with 4 No. 14 x 3½ in. steel screws	Car gainer
					2	Tenons	c	1¼ in. x ½ in. x 1¾ in.	To fit in mortises (a) of the ventilator eaves-rail (2009), Fig. 200	End tenoner
					1	Rabbet	d	¾ in. x ⅝ in.	For ventilator end-sash (4007) to fit in	Shaper
110	8	**Upper-deck compound-carlines** (Fig. 196)	2008	....	..	.....	..	5 ft. 9¼ in. x 1½ in. x 1¼ in.	They being composed of:—	
111	16	**Upper-deck rafters** (Fig. 218)	2007	A.	..	.....	..	5 ft. 9¼ in. x ½ in. x 1¼ in.	In pairs, each having:—	
					2	Tenons	a	1¼ in. x ½ in. x ½ in.	To fit into mortises (c) of the ventilator eaves-rail (2009), Fig. 200	End tenoner
					2	Ogees	b		On one side and at each end of the rafters. These rafters are bolted with 48 bolts 2 in. x ¼ in., round heads, one to each side of the top part (A) of	Chamfering machine
111a	8	**Steel-carlines** (Fig. 206)	2501	W. S.	..	.....	..	9 ft. 11 in. x 1⅛ in. x ½ in.	Each having:—	
					6	Holes	a	5-16 in. diam.	For bolts to secure upper-deck rafters	Drill press
					6	Holes	b	5-16 in. diam.	For bolts to secure lower-deck rafters (2015), Fig. 216. (*See Con. No. 117*)	Drill press
					2	Feet	c	1 in. long	With 7-16 in. hole through them for bolting to side top-rail. The compound carlines are now fixed in the gains (c) of the ventilator top-rails (2001), Fig. 199, and secured with 32 No. 10 x 2 in. steel screws	
112	27	**Upper-deck rafters** (Fig. 217)	2007	A.	..	.....	..	5 ft. 9¼ in. x 1⅛ in. x 1¼ in.	Each having:—	
					2	Tenons	a	1¼ in x 1⅛ in. x ½ in.	To fit into mortises (b) of the ventilator eaves-rail (2009), Fig. 200. These rafters are now fixed in the gains (d) of the ventilator top-rails (2001) and secured with 54 No. 10 x 2 in. steel screws	End tenoner
					4	Ogees	b		One on each side at and each end of the rafters, for ornament	Chamfering machine
113	2	**Ventilator eaves-rails** (Fig. 200)	2009	A.	..	.....	..	About 25 ft. 8 in. x 1¼ x 1¼"	Each having:—	
					2	Mortises	a	1⅜ in. x ½ in.	For tenons (c) of upper-deck head-rafters to fit into	Hollow chisel mortiser
					27	Mortises	b	1⅛ in. x ½ in.	For tenons (a) of upper-deck rafters to fit in	Hollow chisel mortiser
					8	Double mortises	c	½ in. x ½ in.	For tenons (a) of the upper-deck compound-carline rafters (2007) to fit into. (*See Con. No. 111*)	Hollow chisel mortiser
					2	Splice-bevels	d	4 in. long	For splicing to ventilator-hood bow (2011), Fig. 219. Sometimes the mortises into which the upper-deck head-rafters tenon into are in the bow, as shown in Fig. 219, in which case the eaves-rails would be about 24 ft. 7½ in. long. The eaves-rails are fitted to the upper-deck rafter tenons and draw-pinned with 74 hickory dowel-pins	Usually sawed and fitted by hand
114	2	**Ventilator-hood bows** (Fig. 219)	2011	R. E.	..	.....	..	7 ft. to 8 ft. 2 in. x 1¼" x 1¼"	Bent to shape and having:—	
					2	Mortises	a	1⅜ in. x ½ in.	For tenons (c) of upper-deck head-rafters (2006) to fit into	Hollow chisel mortiser
					2	Splice-bevels	b	4 in. long	For splicing to ventilator eaves-rail (2009), Fig. 200; the bows are fitted to the upper-deck head-rafter tenons (c) and draw-pinned with 4 hickory dowel-pins, and also secured to the eaves-rails with 16 No. 10 x 1 in. steel screws	Usually sawed and fitted by hand

115	16	**Compound-carline filling-in pieces** (Not Ill.)	2017	A.	--	----------	--	7 in. x 1¼ in. x ½ in.	Glued between the rafters of the compound-carlines where they project beyond the ventilator top-rails	Band saw
116	16	**Lower-deck compound-carlines** (Fig. 196)	2016	----	--	----------	--	1 ft. 9⅜ in. x 2⅜ in. x 1½ in.	They being composed of :—	Band saw and shaper
117	32	**Lower-deck rafters** (Fig. 216)	2015	A.	--	----------	--	1 in. 9⅜ in. x 2⅜ in. x ½ in.	Each having :—	Band saw and shaper
					1	Tenon	a	¾ in. x ½ in. x ½ in.	To fit in mortises (b) of the ventilator plain-bottom-rails (2002), Fig. 197, to which they are secured with 32 No. 10 x 1 in. steel screws	End tenoner
					1	Gain	b	3¼ in. x 1 in.	To interlock with gains (c) of the side top-rails (1005), Fig. 93, Plate V., and *Con. No. 55, Table No. 33.* These rafters are bolted with 48 bolts 2 in. x ¼ in., round heads, one to each side of the lower projecting piece (B) of the steel carlines described *Con. No. 111*	End tenoner
117a	54	**Lower-deck rafters** (Fig. 215)	2015	A.	--	----------	--	1 ft. 9⅜ in. x 2⅜ in. x 1⅛ in.	Each having :—	
					1	Tenon	a	1⅛ in. x ¾ in. x ½ in.	To fit in mortises (c) of the ventilator plain-bottom-rails (2002), Fig. 197, to which they are secured with 54 No. 10 x 1 in. steel screws	End tenoner
					1	Gain	b	3¼ in. x 1 in.	To interlock with gains (a) of the side top-rails (1005), Fig. 93, Plate V., and *Con. No. 55, Table No. 33.* The skeleton frame-work of the roof as it now appears is shown very clearly in Fig. 196, the lower-deck rafters at the back being omitted, so as to show more clearly the general construction	End tenoner
118	2	**Roofing-boards** (Fig. 208)	2014	P.	--	----------	--	26 ft. 6 in. x 13 in. x ⅜ in.	Beaded on the under side to represent single strips are now laid in white-lead lengthwise over the projecting portion of the upper-deck rafters next the eaves-rails, and are secured to the rafters with 222 No. 10 x 1¼ in. steel screws, and to the ventilator top-rails, eaves-rails and hood-bows with 160 No. 10 x 1¼ in. steel screws ; the intervening space between these two boards is then filled up with	Flooring machine
118a	15	**Roofing-boards** (Fig. 209)	2014	P.	--	----------	--	26 ft. 6 in. x 3 in. x ⅜ in.	Beaded on one edge, nailed to the upper-deck rafters and ventilator hood-bows with clout-nails	Flooring machine
119	68	**Upper-deck furring-pieces** (Fig. 224)	2021	A.	--	----------	--	6¾ in. x 2⅜ in. x 1¼ in.	And	
	4	**Upper-deck furring-pieces** (Fig. 225)	2021	A.	--	----------	--	9½ in. x 2⅜ in. x 1¼ in.	Screwed to the roofing-boards between the upper-deck rafters, and alongside the ventilator top-rail with 76 No. 10 x 1¼ in. steel screws The roof is now ready to be attached to the car body, in the condition we left it in at the end of Table No. 33, the order of procedure being	
119b	--	**Steel-carlines** (Fig. 206)	2501	----	--	----------	--		See *Con. No. 111*, are bolted through the holes in the feet (c) to the side top-rails with 16 bolts, 3¾ in. x ⅜ in.	
119c	--	**Lower-deck rafters** (Figs. 215, 216)	2015 2016	----	--	----------	--		See *Con. No. 117*, nave their gains (b) well varnished, interlocked with gains (a and c) of the side top-rails, and screwed to the latter with 86 No. 12 x 1½ in. steel screws	
120	2	**Side-roof joint-breakers** (Not Ill.)	2025	A.	--	----------	--	25 ft. 0¾ in. x 1½ in. x ½ in.	Are nailed to the outside of the side top-rails (1005) above the rabbet (b) for the letter-board. (*See Fig. 93, Plate V. and Con. No. 55, Table No. 33*)	
120a	--	**Ventilator plain-bottom-rails** (Figs. 197, 198)	2002	----	--	----------	--		Are adjusted to notches (b), Fig. 109, Plate V., of the end top-rail (1006) and screwed to it with 4 No. 16 x 3 in. steel screws	
120b	--	**Ventilator end-corner posts** (Figs. 211, 212)	2004	----	--	----------	--		Are adjusted to rabbets (c), Fig. 108, Plate V., of the end top-rail (1006) and screwed to it with 4 No. 12 x 1½ in. steel screws	
120c	2	**Roofing-boards** (Fig. 208)	2014	P.	--	----------	--	25 ft. 0 in. x 14 in. x ½ in.	Are laid in white-lead, and screwed to the lower-deck rafters and side top-rails with 144 No. 10 x 1¼ in. steel screws, their lower edges forming the eaves of the lower-deck. The remaining space up to the ventilator plain-bottom-rails is filled with	
20d	6	**Roofing-boards** (Fig. 209)	2014	P.	--	----------	--	25 ft. 0 in. x 3 in. x ½ in.	Nailed to the lower-deck rafters, fit in the rabbets (e) of the ventilator plain-bottom-rails and screwed to the end top-rails with 12 No. 10 x 1¼ in. steel screws	
121	2	**Upper-deck end-furring pieces** (Fig. 230)	2023	A.	--	----------	--	3 ft. 6⅝ in. x 2½ in. x 1¼ in.	Screwed to the upper-deck roofing-boards close up against the end top-rails with 10 No. 10 x 1¼ in. steel screws	
122	72	**Lower-deck furring-pieces** (Fig. 223)	2024	A.	--	----------	--	6¾ in. x 1¾ in. x 1¼ in.	Screwed to the lower-deck roofing-boards centrally between the rafters with 72 No. 10 x 1¼ in. steel screws	
123	1	**White duck** (Not Ill.)	2020	----	--	----------	--	8 ounce	Is now laid all over the upper-deck roof in thick paste, composed of whiting mixed with linseed oil and japan, carefully stretched and tacked all round to the sides of the ventilator eaves-rails and hood-bows, after which	
124	4	**Ventilator hood-bow lead-moldings** (Fig. 221)	2503	----	--	----------	--	¾ in. half-round	Are nailed over the duck to the sides of the corners of the hood-bows	
125	2	**Ventilator eaves-moldings** (Fig. 203)	2010	A.	--	----------	--	¾ in. half-round	Are nailed over the duck to the sides of ventilator eaves-rails	Molding machine
126	2	**Ventilator hood-bow moldings** (Not Ill.)	2012	P.	--	----------	--	¾ in. half-round	Same as Fig. 203, nailed over the duck to the sides of the hood-bows in continuation of the lead moldings at the corners	Molding machine
126a	1	**White duck** (Not Ill.)	2020	----	--	----------	--	8 ounce	Is laid over the two lower-deck roofs in similar manner to the upper-deck, and tacked to the side-roof joint-breakers (2025), and further secured by	
127	2	**Ventilator bottom-rail roof-moldings** (Fig. 201)	2027	P.	--	----------	--	25 ft. 0 in. x 2¾ in. x ⅜ in.	Inserted in the rabbet (e) of the ventilator plain-bottom-rail (2002), Fig. 197, and nailed to the roof	Molding machine
128	2	**Lower-deck eaves-moldings** (Fig. 207)	2026	A.	--	----------	--	¾ in. half-round	Are nailed over the duck to the sides of the side-roof joint-breakers, after which the roofs receive three coats of white-lead all over the duck	Molding machine
									The preparation of the outside of the car body previous to painting and finishing is now proceeded with as follows :—1st and 2d days—One coat of permanent wood priming, consisting of oil and white-lead laid all over. 3d and 4th days—Two coats of lead priming (white-lead with a little oil). 5th day—Fill all holes and depressions with putty. 6th day—Scrape soft putty in open grains and give first coat of roughstuff. 7th and 8th days—Second and third coats of roughstuff. 9th day—Rub the roughstuff with pumice stone and water to bring to a smooth surface. The cars are now externally in what is termed "the white," ready to receive later their coats of color, as shown in Fig. 107, Plate V.	
									The under surfaces of the roofing-boards receive a coat of boiled oil	
									The top side of the flooring receives two coats of boiled oil	
									It is usual at this stage to attach the platforms to the body, but as their description includes a number of accessories related to "traction" they will be dealt with in a separate table, and	
129	--	**Platform-hoods** (Figs. 226, 227)	2029	----	--	----------	--		(Often called bonnets) will now be taken up. They are made independently whilst the construction of the body as described is in progress, and consist of :—	
129a	2	**Platform-hood bows** (Fig. 228)	2032	R. E.	--	----------	--	2 in. x 1⅜ in.	Steamed and bent to shape on a form, each having :—	
					2	Gains	a		For platform-hood shoulder-carline (2030), Fig. 231	Gainer
					6	Gains	b		For platform-hood rafters (2031), Fig. 232	Gainer
					1	Chamfer	c		For ornament, seen in Fig. 226	Chamfering machine
130	2	**Platform-hood shoulder-carlines** (Fig. 231)	2030	A.	--	----------	--	1 7-16 in. x 1¼ in.	Steamed and bent to shape on a form, each having :—	
					2	Gains	a		To interlock with gains (a) of the platform-hood bows, to which they are screwed with 4 No. 12 x 1 in. steel screws.	End tenoner
					1	Chamfer	b		For ornament	Chamfering machine
131	6	**Platform-hood rafters** (Fig. 232)	2031	A.	--	----------	--	1¼ in. x 1 in.	Steamed and bent to shape on a form, each having :—	
					2	Gains	a		To interlock with gains (b) of the platform-hood bows, to which they are screwed with 12 No. 10 x 1 in. and 12 No. 10 x ¾ in. steel screws	End tenoner
					2	Chamfers	b		For ornament, seen in Fig. 226	Chamfering machine
131a	33	**Roofing-boards** (Fig. 226)	2014	P.	--	----------	--	3 in. x 5-16 in.	Beaded and nailed to platform-hood bows, shoulder-carlines and rafters	Flooring machine
131b	1	**White duck** (Not Ill.)	2020	----	--	----------	--	8 ounce	Is now laid and stretched over the roof in soft white-lead paint, tacked to the bows and further secured by	
132	2	**Platform-hood iron-moldings** (Not Ill.)	2506	W. I.	--	----------	--	¾ in. half-round	Screwed to the bows with 54 No. 12 x 1¼ in. steel screws. The duck is then given three successive coats of white-lead, and when dry the platform-hoods are attached to the car body with 18 No. 16 x 2½ in. round-headed steel screws and washers screwed through the shoulder-carlines into the end top-rails. Further security is given by	
133	4	**Platform-hood brackets** (Fig. 238)	2507	M. I.	--	----------	--		Screwed to the corner-posts and platform-hoods with 36 No. 12 x 1¼ in. steel screws	

TABLE No. 35—*Continued*

Consecutive Number	Quantity	Name of Piece	Piece Number Plates I. and VII.	Material See Plates I and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate VII	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
134	2	**Platform-hood shoulder-carline moldings** (Fig. 229)	2034	P.	..	.....	..	½ in. quarter-round	Nailed to the end top-rails and the top of the platform-hood, the ends joining the ventilator bottom-rail roof-molding (2027) on each side of the ventilator. (*See Con. No. 126*)	Molding machine
135	4	**Platform-hood joint-straps** (Fig. 233)	2505	W. I.	..	.....	..	20 in. x 1¾ in. x ⅛ in.	Are screwed over the joining of the platform-hood roof to the lower-deck roof, with 36 No. 10 x 1¼ in. steel screws	
136	2	**Platform-hood watersheds** (Fig. 230)	2052	A.		.....	..	1 ft. 10 in. x ½ in. x ½ in.	Screwed to the top front of the platform-hood with 14 No. 4 x 1 in. and 4 No. 4 x 1¼ in. steel screws	
137	16	**Steel-carline covers** (Fig. 214)	2502	Tin	..	.....	..		Nailed to ventilator side-posts and bottom-rail roof moldings	
138	2	**Trolley cord guards** (Fig. 222)	2508	W. I.	..	.....	..		Screwed to under side of platform-hood bows (2032) with 8 No. 14 x 1½ in. steel screws	
139	..	**One trolley-bridge**	....	....	..	.....	..		Is independently put together, and then attached to the roof. It consists of	
139a	2	**Trolley-board long-rails** (Fig. 244)	2035	A.	..	.....	..	8 ft. 0 in. x 3 in. x 1¾ in.	These are bolted to	Planer and shaper
140	4	**Trolley-board short-rails** (Fig. 245)	2036	A.	..	.....	..	4 ft. 2½ in. x 2½ in. x 2 in.	With 8 bolts 4 x 5-16 in. The frame formed by these rails is placed on the roof in the center of the car, the long rails lying exactly over the ventilator side top-rails, bedded in soft white-lead and screwed to the upper-deck roof with 12 No. 20 x 4 in. steel screws	Planer and shaper
141	2	**Trolley-boards** (Fig. 243)	2037	A.	..	.....	..	8 ft. 0 in. x 6 in. x 2 in.	Are then screwed side-by-side to the center of the trolley-board short-rails (2036) with 16 No. 10 x 3½ in. steel screws. In the center of these are four bolt holes, 9-16 in. diam. for 4 x ½ in. bolts, whose heads are let in flush on the underside and covered with leather to prevent their falling out; they serve to hold the trolley-base in place	Planer
142	..	**Two upper-deck landings** (Fig. 239)	2038	A.	..	.....	..		Are now secured to the upper-deck roof at each end, meeting the trolley-boards in the center; they are composed of	
142a	4	**Upper-deck landing-battens** (Fig. 237)	2041	A.	..	.....	..	3 ft. 4½ in. x 2 in. x ⅝ in.	Curved to the arc of the roof, and	Band saw and shaper
142b	6	**Upper-deck landing-battens** (Fig. 236)	2041	A.	..	.....	..	1 ft. 3¼ in. x 2 in. x ⅝ in.	To which are secured	Band saw and shaper
143	6	**Upper-deck landing-slats** (Fig. 234)	2039	A.	..	.....	..	8 ft. 7½ in. x 3 in. x ⅝ in.	And	Planer
143a	10	**Upper-deck landing-slats** (Fig. 235)	2039	A.	..	.....	..	2 ft. 6½ in. x 3 in. x ⅝ in.	With 100 No. 10 x 1¼ steel screws. The battens being laid in soft white-lead, the landings are then screwed to the roof with 42 No. 12 x 2 in. and 42 No. 12 x 1½ in. steel screws	Planer
144	..	**Two lower-deck landings** (Fig. 241)	2043	A.	..	.....	..		Are now screwed to diagonally opposite corners of the lower-deck roof, being composed of	
144a	4	**Lower-deck landing-battens** (Fig. 240)	2045	A.	..	.....	..	1 ft. 1 in. x 1½ in. x ⅝ in.	To which are screwed	Planer
145	10	**Lower-deck landing-slats** (Fig. 242)	2044	A.	..	.....	..	2 ft. 5½ in. x 1½ in. x ⅝ in.	With 40 No. 10 x 1¼ in. steel screws. The battens are laid in soft white-lead and the landings screwed to the roof with 4 No. 12 x 2 in. and 4 No. 12 x 1½ in. steel screws	Molding machine
									These cars have in some cases six direction signs, and in others eight, on the roofs and bonnets covering five different varieties which will now be described	
146	2	**Lower-deck sign-boards, 1 side** (Fig. 246)	2046	P.	..	.....	..	15 ft. 6 in. x 5 in. x ¾ in.	Ornamental ends, one on each side of the car, with 3 holes on under side to fit on the sign-board pins (2510), Fig. 254	Planer and chamfering machine
147	6	**Sign-board washers** (Fig. 263)	2511	M. I.	..	.....	..		Screwed to under side of the boards with 12 No. 12 x 1½ in. steel screws, to protect the holes for the pins named above, Con. No. 146	
148	6	**Sign-board pins** (Fig. 254)	2510	M. I.	..	.....	..		Screwed to the sides of the lower-deck roof with 18 No. 12 x 1½ in. steel screws	
149	..	**Lower-deck box-signs**	....	....	..	.....	..		Are used in some cases, one on each side on the lower deck roof; they are four-sided, and consist of	
149a	8	**Sign-box boards** (Fig. 247)	2047	D.	..	.....	..	8 ft. 4 in. x 4¾ in. x ½ in.	With ornamental ends, fitted together in box-form, by being bolted to	Planer and chamfering machine
150	4	**Sign-box pivots** (Fig. 251)	2512	M. I.	..	.....	..		With 32 carriage bolts 1 x ¼ in. In the center of the boxes and to stiffen them	
151	2	**Sign-box blocks** (Fig. 260)	2051	A.	..	.....	..	4¾ in. x 4¾ in. x 1 in.	Are inserted and screwed to the sign-boards with 16 No. 12 x 1¼ in. steel screws	
152	4	**Sign-box brackets** (Fig. 250)	2513	M. I.	..	.....	..		To receive the pivots, are screwed to the sides of the lower deck roof with 20 No. 12 x 1¼ in. round-headed steel screws. To keep the boxes in their brackets	
153	4	**Sign-box pivot-washers** (Fig. 261)	2521	M. I.	..	.....	..		Are slipped over the projecting stud of the pivot and secured with	
154	4	**Sign box pivot-cotters** (Not Ill.)	2522	W. S.	..	.....	..		Passed through the holes at the ends of the studs	
155	2	**Upper-deck end sign-boards, 1 side** (Fig. 256)	2048	P.	..	.....	..	4 ft. 4½ in. x 5 in. x ¾ in.	With ornamental ends, one at each end of the monitor roof, with 2 holes on under side to fit on the sign-board pins (2514), Fig. 255	Band saw and shaper
156	4	**Sign-board washers** (Fig. 264)	2515	M. I.	..	.....	..		Screwed to under side of above boards with 8 No. 12 x 1½ in. steel screws, to protect the pin-holes in the boards	
157	4	**Sign-board pins** (Fig. 255)	2514	M. I.	..	.....	..		Screwed to the ends of the upper-deck roof with 8 No. 12 x 1½ in. steel screws	
158	2	**Upper-deck sign-boards, 2 sides** (Fig. 248)	2049	P.	..	.....	..	7 ft. 2 in. x 5 in. x ¾ in.	With round ends, one at each side of the car on the upper-deck, secured to	Planer
159	4	**Sign-board pivots** (Fig. 258)	2516	M. I.	..	.....	..		With 16 No. 12 x ¾ in. steel screws	
160	4	**Sign-board brackets** (Fig. 253)	2517	M. I.	..	.....	..		To receive the pivots are screwed to the sides of the upper-deck roof with 12 No. 12 x 1¼ in. round-headed screws; they are held in place with	
160a	4	**Sign-board pivot-washers** (Fig. 261)	2521	M. I.	..	.....	..		Same as Con. No. 152, and	
160b	4	**Sign-board pivot-cotters** (Not Ill.)	2522	W. S.	..	.....	..		Same as Con. No. 153	
161	4	**Sign-board guards** (Not Ill.)	2523	W. I.	..	.....	..	3½ in. half-round	Same as (2506) No. 132, are screwed to each side of the sign-boards with 56 No. 12 x 1½ in. steel screws	
162	..	**Bonnet box-signs** (Not Ill.)	....	....	..	.....	..		Two in number, consisting of	
162a	8	**Sign-box boards** (Fig. 257)	2050	P.	..	.....	..	3 ft. 7¼ in. x 5 in. x ½ in.	With ornamental ends fitted together in box-form by being bolted to	Planer and chamfering machine
163	4	**Sign-box pivots** (Fig. 252)	2518	M. I.	..	.....	..		And	
164	4	**Sign-box frames** (Fig. 259)	2520	M. I.	..	.....	..		With 48 carriage bolts 1 x ¼ in.	
165	4	**Sign-box brackets** (Fig. 249)	2519	M. I.	..	.....	..		To receive the pivots are bolted and screwed to the platform-hoods with 12 round-headed stove-bolts 1 x ¼ in. and 4 No. 12 x 1¼ in. round-headed steel screws	
165a	4	**Sign-box pivot-washers** (Fig. 261)	2521	M. I.	..	.....	..		Same as Con. No. 152, and	
165b	4	**Sign-box pivot-cotters** (Not Ill.)	2522	W. S.	..	.....	..		Same as Con. No. 153	
									Before putting these signs together the boards are primed all over with lead containing oil, then the backs receive two coats of white-lead. After the box signs are fitted to the pivots they, as well as the single sign-boards, are treated as follows:—1st day—All holes and depressions filled with putty. 2d day—Scrape soft putty in open grains, etc. 3d day—Ground coat of white-lead tinted with color. 4th day—First coat of color. 5th day—Second coat of color with varnish to make a gloss. 6th day—Apply the letters as required. 7th and 8th days—Two coats of railway coach finishing varnish. The colors are various, some of the signs being buff, some vermilion and some white. The platforms and accessories will be treated of next. *See Con. No. 166, Table No. 37 and Plates I. and IX.*	

Number of Distinctive Pieces.... 62 (Column 1)

TABLE NO. 36

DETAIL OF ROOFS AND BONNETS OF BROOKLYN OPEN CAR, IN THE ORDER OF ASSEMBLING

(12 Benches; Car No. 4; Fig. 5; Plates II. and VIII.)

Consecutive Number	Quantity	Name of Piece	Piece Number Plates II. and VIII.	Material See Plates I. and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate VIII.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
									During the erection of the sides and ends of the body (see Table No. 34 and Plate VI.) the assembling of the pieces composing the framework of the "Monitor" roof has been proceeded with in a similar manner to that of the closed car, as described in Table No. 35	
66	2	**Ventilator plain bottom-rail** (Fig. 266)	7021	Y. P.	--	----------	--	26 ft. 3¼ in. x 2¾ in. x 1½ in.	Each having:—	
					2	Mortises	--	3 in. x 1 in. x ½ in.	Not seen, one at each end, for ventilator side-corner-posts (7003), Fig. 272, to tenon into, with two holes for dowel-pins	Hollow chisel mortiser
					10	Mortises	--	1⅞ in. x 1 in. x ½ in.	Not seen, for ventilator side-posts (7005) to tenon into, with holes for dowel-pins	Hollow chisel mortiser
					2	Mortises	a	1⅞ in. x ¾ in. x ½ in.	For lower-deck thick-rafters (7011) to tenon into	Hollow chisel mortiser
					18	Mortises	b	13-16 in. x ¾ in. x ½ in.	For lower-deck thin-rafters (7012) to tenon into	Hollow chisel mortiser
					8	Double mortises	c	13-16 in. x ¾ in. x ½ in.	For lower-deck rafters for compound-carlines (7013) to tenon into	Hollow chisel mortiser
					1	Groove	d	Full length x ⅜ in. x ⅜ in.	For roofing-boards (7016) to fit in	Molding machine
67	4	**Ventilator side-corner-posts** (Fig. 272)	7003	A.	--	----------	--	10⅝ in. x 3⅝ in. x 1½ in.	Each having:	
					1	Double tenon	a	3 in. x 1 in. x ½ in.	Tenoned into end mortises of ventilator bottom rail (7021), glued and secured with two hickory dowel-pins	Double end tenoner
					1	Tenon	b	1¼ in. x 1 in. x ½ in.	To tenon into end mortises of ventilator top-rail (7001), Fig. 265	Double end tenoner
68	20	**Ventilator side-posts** (Fig. 275)	7005	A.	--	----------	--	10⅝ in. x 1⅞ in. x 1½ in.	Each having:—	
					1	Tenon	a	1⅞ in. x 1 in. x ½ in.	Tenoned into mortises of ventilator bottom-rail (7021) and secured with hickory dowel-pins	Double end tenoner
					1	Tenon	b	1⅞ in. x 1 in. x ½ in.	To tenon into mortises (e) of ventilator top-rail (7001)	Double end tenoner
69	2	**Ventilator top-rails** (Fig. 265)	7001	Y. P.	--	----------	--	26 ft. 1¾ in. x 2½ in. x 1½ in.	Each having:—	
					2	Tenons	a	1½ in. x 1 in. x ¾ in.	To tenon into mortise in upper-deck head-rafter (7007), Fig. 267	End tenoner
					2	Mortises	--	1¼ in. x 1 in. x ½ in.	Not seen, one at each end on the underside for ventilator side-corner-posts to tenon-into, with hole for dowel-pin	Holllow chisel mortiser
					2	Gains	b	1⅞ in. x 1⅜ in.	For upper-deck thick-rafters (7008) to fit in	Multiple gainer
					18	Gains	c	13-16 in. x 1⅜ in.	For upper-deck thin-rafters (7009) to fit in	Multiple gainer
					8	Gains	d	1⅞ in. x 1⅜ in.	For upper-deck compound-carlines (7010) to fit in	Multiple gainer
					10	Mortises	e	1⅞ in. x 1 in. x ½ in.	To receive tenons (b) of the ventilator side-posts (7005)	Hollow chisel mortiser
70	4	**Ventilator end-corner-posts** (Fig. 273)	7004	A.	--	----------	--	11 3-16 in. x 2½ in. x 1¾ in.	Each having:—	
					1	Tenon	a	2 in. x 1⅞ in. x ½ in.	To fit in mortise (e) of the end top-rail (6006), Figs. 150 to 152, Plate VI. (*See Con. No. 31, Table No. 34*)	Double end tenoner
					1	Tenon	b	2¼ in. x 1¾ in. x ½ in.	To fit in mortise (b) of the ventilator upper-deck head-rafter (7007), Fig. 267	Double end tenoner
					1	Rabbet	c	½ in. x 5-16 in.	For ventilator end-sign-sash to fit in. The end-corner-posts are also secured to the side-corner-posts with 8 No. 14 x 2½ in. steel screws	Molding machine
71	2	**Upper-deck head-rafters** (Fig. 267)	7007	A.	--	----------	--	5 ft. 6½ in. x 2¼ in. x 1¾ in.	Each having:	
					2	Tenons	a	1¾ in. x ¾ in. x ½ in.	To fit in mortises in the ventilator eaves-rail (7014)	Double end tenoner
					2	Mortises	b	2¼ in. x 1¾ in. x ½ in.	On the underside to receive the tenons (b) of the end-corner-posts, the same being glued and secured with dowel-pins	Hollow chisel mortiser
					2	Rabbets	--	1½ in. x 1 in. x ¾ in.	On the other side, to receive the tenons (a) of the ventilator top-rails, Fig. 265 (7001), they are secured with 4 No. 14 x 3½ in. steel screws	Multiple gainer
					2	Mortises	c	2 in. x 1¼ in. x ½ in.	On the underside to receive the tenons (b) of the ventilator end-center-posts (7006), Fig. 276	Hollow chisel mortiser
					2	Rabbets	d	½ in. x 5-16 in.	For ventilator end-sign-sash to fit in	Shaper
72	2	**Upper-deck thick-rafters** (Fig. 268)	7008	A.	--	----------	--	5 ft. 6½ in. x 1⅞ x 1 5-16 in.	Each having:	
					2	Tenons	a	1⅞ in. x ¾ in. x ½ in.	To fit in mortises in the ventilator eaves-rail (7014), to which they are secured with dowel-pins	Double end tenoners
					2	Gains	b	1½ in. x ½ in. x ⅛ in.	To interlock with gains (b) of the ventilator top-rail (7001), to which they are secured with 4 No. 10 x 2 in. steel screws	Multiple gainer
					4	Chamfers	c		For ornament	Shaper
73	18	**Upper-deck thin-rafters** (Fig. 270)	7009	A.	--	----------	--	5 ft. 6½ in. x 13-16 x 1 5-16 in.	Each having:	
					2	Tenons	a	13-16 in. x ¾ in. x ½ in.	To fit in mortises in the ventilator eaves-rail (7014), to which they are secured with dowel-pins	Double end tenoner
					2	Gains	b	1½ in. x ½ in. x ⅛ in.	To interlock with gains (c) of the ventilator top-rail (7001), to which they are secured with 36 No. 10 x 2 in. steel screws	Multiple gainer
					4	Chamfers	c		For ornament	Shaper
74	--	**Upper-deck compound-carlines** (Fig. 271)	7010	----	--	----------	--		Composed of	
74a	16	**Upper-deck thin-rafters** (Fig. 269)	7009	A.	--	----------	--	5 ft. 6½ in. x 13-16 x 1 5-16 in.	In pairs, same as Con. No. 73, but with the chamfer (c) on one side only; these rafters are bolted with 32 bolts, 2¼ in. x ¼ in., round heads, one to each side of the top part of	
75	8	**Steel carlines** (Fig. 271)	7501	W. S.	--	----------	--	1¼ in. x 5-16 in.	Each having:	
					4	Holes	a	5-16 in. diam.	On the top for bolts to secure upper-deck rafters	Power punch
					6	Holes	b	5-16 in. diam.	In the side projections for bolts to secure the lower-deck rafters	Power punch
									The compound-carlines are now fitted in the gains (d) of the ventilator top-rails (7001) and secured with 32 No. 10 x 2 in. steel screws	
76	2	**Ventilator eaves-rails** (Not Ill.)	7014	Y. P.	--	----------	--	27 ft. 7¾ in. x 1½ in. x 1¼ in	Each having:—	
					2	Tenons	--	1½ in. x ¾ in. x ½ in.	One at each end, to fit into mortises (a) of the ventilator-hood bow (7015), Fig. 279	End tenoner
					2	Mortises	--	1¾ in. x ¾ in. x ½ in.	To receive the tenons (a) of the upper-deck head-rafters	Hollow chisel mortiser
					2	Mortises	--	1⅞ in. x ¾ in. x ½ in.	To receive the tenons (a) of the upper-deck thick-rafters	Hollow chisel mortiser
					9	Mortises	--	13-16 in. x ¾ in. x ½ in.	To receive the tenons (a) of the upper-deck thin-rafters	Hollow chisel mortiser
					8	Double mortises	--	13-16 in. x ¾ in. x ½ in.	To receive the tenons (a) of the upper-deck compound-carlines. The eaves-rails are fitted to the various upper-deck rafters, and draw-pinned with hickory dowel-pins	Hollow chisel mortiser
77	2	**Ventilator hood-bows** (Fig. 279)	7015	A.	--	----------	--	5 ft. 8 in. x 1 5-16 in. x 1 in.	Each having:	
					2	Mortises	a	1½ in. x ¾ in. x ½ in.	To receive the end tenons of the ventilator eaves-rails, which are secured with dowel-pins	Hollow chisel mortiser
78	16	**Compound-carline filling-in pieces** (Fig. 287)	7028	A.	--	----------	--	7⅜ in. x 1¾ in. x ¼ in.	Glued between the rafters of the compound-carlines where they project beyond the ventilator top-rails	
79	4	**Lower-deck thick-rafters** (Fig. 278)	7011	A.	--	----------	--	20 in. x 1⅞ in. x 1 5-16 in.	Each having:	
					1	Tenon	a	1⅞ in. x ¾ in. x ½ in.	To fit in mortises (a) of the ventilator bottom-rail	End tenoner
					1	Gain	b	2¼ in. x 7-16 in.	To fit the gains (c) of the side top-rails (6018), Fig. 163, Plate VI.	Band saw

TABLE No. 36—*Continued*

Consecutive Number	Quantity	Name of Piece	Piece Number Plates II. and VIII.	Material See Plates I. and II.	Details: Quantity	Details: Name	Reference Letter Plate VIII.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
80	36	**Lower-deck thin-rafters** (Fig. 277)	7012	A.	--	----------	--	20 in. x 13 16 in. x 1 5-16 in.	Each having:	
					1	Tenon	a	13-16 in. x ¾ in. x 1⅝ in.	To fit in mortises (b) of the ventilator bottom-rail	
81	--	**Lower-deck compound-carlines**	7013	----	1	Gain	b	2¼ in. x 7-16 in.	To fit the gains (d) of the side top-rails (6018), Fig. 163, Plate VI.	End tenoner
81a	32	**Lower-deck thin-rafters** (Fig. 277)	7012	A.	--	----------	--	20 in. x 13-16 in. x 1 5-16 in.	Composed of	Band saw
									In pairs same as Con. No. 80; these rafters are bolted with 48 bolts, 2¼ in. x ¼ in., round heads, one to each side of the lower projecting pieces of the steel-carlines described, Con. No. 74, and shown in Fig. 271, and fit in gains (b) of the side top-rails (6018), Fig. 163, Plate VI.	
82	2	**Ventilator end-center-posts** (Fig. 276)	7006	A.	--	----------	--	10 9-16 in. x 2 in. x 1¾ in.	Each having:—	
					1	Tenon	a	1½ in. x 2 in. x ½ in.	To fit mortise (d) of the end top-rail (6006), Figs. 150 to 152, Plate VI.	Double end tenoner
					1	Tenon	b	2 in. x 1¼ in. x ½ in.	To fit in mortise (c) of the upper-deck head-rafter (7007), Fig. 267, both of which are secured with wood dowel-pins	Double end tenoner
83	20	**Roofing-boards** (Not Ill.)	7016	P.	--	----------	--	3½ in. wide, ⅜ in. thick	Nailed to the upper-deck rafters, hood-bows and eaves-rails with clout-nails. The roof is now ready to be attached to the car body, in the condition in which it was at the end of Table No. 34	Tongued and grooved and beaded on flooring machine
83a	--	**Lower-deck rafters**	----	----	--	----------	--		See Con. Nos. 79, 80, 81 have their gains (b) fitted to the gains of the side top-rails, and are screwed to them with 72 No. 12 x 1½ in. steel screws	
83b	--	**Ventilator end-corner** and **end-center-posts**	----	----	--	----------	--		Are tenoned into mortises (e) and (d) in the end top-rail, Figs. 150 to 152, Plate VI., and secured with dowel-pins	
83c	--	**Ventilator bottom-rails**	----	----	--	----------	--		Are tenoned and pinned to the end top-rails	
83d	12	**Roofing-boards** (Not Ill.)	7016	P.	--	----------	--	3½ in. wide, ⅜ in. thick	Nailed to the lower-deck rafters and end top-rails	
84	2	**Upper-deck end-furring pieces** (Fig. 285)	7027	Y. P.	--	----------	--	3 ft. 11¾ in. x 2 in. x 1¼ in	Nailed to upper-deck head-rafters	
85	1	**White duck** (Not Ill.)	7023	----	--	----------	--	No. 10.	Is now laid all over the upper-deck in thick paste composed of whiting mixed with linseed oil and japan, carefully stretched and tacked all around to the sides of the ventilator eaves-rails and hood-bows, after which	
86	2	**Ventilator eaves-moldings** (Not Ill.)	7028	----	--	----------	--	⅝ in. half-round	Are nailed over the duck to the sides of the ventilator eaves-rails and hood-bows	Molding machine
87	2	**Ventilator hood-bow lead-moldings** (Not Ill.)	7503	----	--	----------	--	⅝ in. x ⅜ in. half-oval	Nailed over the duck to the sides of the corners of the hood-bows	
87a	1	**White-duck** (Not Ill.)	7023	----	--	----------	--	No. 10	Is laid over the lower-deck roofs in similar manner to the upper-deck and secured with	
88	2	**Lower-deck eaves-moldings** (Not Ill.)	7025	----	--	----------	--	⅝ in. x ⅜ in. half-oval	Nailed over the duck to the side top-panel (6020), *see Con. No. 47, Table No 34 and Fig. 105, Plate VI.*; the roofs then receive three coats of white-lead all over the duck	Molding machine
89	2	**Ventilator bottom-rail roof-moldings** (Fig. 293)	7026	P.	--	----------	--	27 ft. 0 in. x 2 in. x ½ in.	Nailed to the roof against the ventilator bottom-rail	Molding machine
90	--	**Platform-hoods** (Fig. 280)	7017	----	--	----------	--		As in the case of closed cars, Table No. 36, we will now take up Made independently during the progress of construction already described, and consisting of	
90a	2	**Platform-hood bows** (Fig. 284)	7020	R. E.	--	----------	--	15 ft. 0 in x 1¼ in. x 1¼ in.	Steamed and bent to shape on a former, each having:—	
					2	Gains	a	1¼ in x ⅜ in.	For platform-hood shoulder-carlines (7018), Fig. 283	Multiple gainer
					8	Gains	b	¾ in. x ⅜ in	For platform-hood rafters (7019), Fig. 282	Multiple gainer
91	2	**Platform-hood shoulder-carlines** (Fig. 283)	7018	A.	--	----------	--	7 ft. 1¼ in. x 1 9-16 x 1¼ in.	Steamed and bent to shape on a former, each having:—	
					2	Gains	a	1¼ in. x ⅜ in.	To interlock with gains (a) of the platform-hood bows, to which they are secured with 4 No. 12 x 1 in. steel screws	Multiple gainer
92	8	**Platform-hood rafters** (Fig. 282)	7019	A.	--	----------	--	1⅛ in. x ¾ in.	Steamed and bent to shape on a former, each having:—	
					2	Gains	a	¾ in. x ⅜ in.	To interlock with gains (b) of the platform-hood bows, to which they are secured with 16 No. 10 x 1 in. and 16 No. 10 x ¾ in. steel screws	Band saw
92a	58	**Roofing-boards** (Fig. 280)	7016	P.	--	----------	--	3 in. x ¼ in.	Beaded, nailed to platform-hood bows, shoulder-carlines and rafters	Flooring machine
92b	1	**White-duck** (Not Ill.)	7023	----	--	----------	--	No. 10	Is now laid and stretched over the roofing-boards in soft white-lead paint, tacked to the bows and further secured by	
93	2	**Platform-hood iron-moldings** (Fig. 281)	7504	W. I.	--	----------	--	4 ft. 0 in. x ¾ in. half-round	Nailed to the middle portion of the bows over the duck, and	
94	4	**Platform-hood moldings** (Not Ill.)	7029	P.	--	----------	--	⅝ in. x ⅜ in. half-oval	Nailed to the sides of the bows over the duck. The duck is then given three successive coats of white-lead, and when dry the platform-hoods are attached to the car body with 28 round-head screws and washers, No. 14 x 3 in., screwed through the shoulder-carline into the end top rails, while further security is obtained by	Molding machine
95	4	**Platform-hood brackets** (Fig. 274)	7505	Bz.	--	----------	--		Screwed to the platform-hoods and corner-posts with 12 No. 12 x 1¼ in. steel screws, and bolted to the corner-posts with four bolts, 3⅞ in. x ⅜ in., round heads and bronze nuts	
96	2	**Platform-hood shoulder-carline moldings** (Not Ill.)	7030	P.	--	----------	--	½ in. x ⅜ in. quarter-round	Nailed to the end top-rails and the top of the platform-hoods, the ends joining the ventilator bottom-rail roof-moldings (7026) on each side of the ventilator	Molding machine
97	4	**Lamp-blocks** (Fig. 288)	7022	A.	--	----------	--	9⅜ in. x 7 in. x 1 5-16 in.	Nailed to the under-side of the upper-deck rafters, having a groove and hole in each for the electric wires	
98	16	**Steel-carline tin-covers** (Not Ill.)	7502	Tin	--	----------	--		Nailed to the ventilator side-posts and bottom-rail roof-moldings over the projecting portion of steel-carlines	
99	76	**Trolley-board cleats** (Fig. 286)	7031	A.	--	----------	--	9½ in. x 1⅞ in. x 1⅜ in.	Screwed to the upper-deck roof-rafters with 152 No. 12 x 1⅛ in. and 152 No. 12 x 1¾ in. steel screws	Shaper
100	2	**Trolley-boards** (Fig. 292)	7032	O.	--	----------	--	26 ft. 8½ in. x 6 in. x 1½ in.	Each in two lengths, laid side by side and screwed to the cleats with 76 No. 16 x 3½ in. steel screws	Planer
101	1	**Trolley base-block** (Fig. 289)	7033	O.	--	----------	--	2 ft. 0 in. x 14 in. x 2 in.	Screwed to the center of the trolley-boards with 12 No. 16 x 3½ in. steel screws	Planer
102	--	**Upper-deck landings** (Fig. 291)	7034	A.	--	----------	--		Are now screwed to the upper-deck roof on opposite corners with 8 No 12 x 2 in. steel screws; the two of them are composed of:—	
102a	6	**Upper-deck landing-battens** (Fig. 291)	7036	A.	--	----------	--	17⅝ in. x 1⅞ in. x ⅜ in.	To which are screwed	Planer
103	16	**Upper-deck landing-slats** (Fig. 291)	7035	A.	--	----------	--	3 ft. 2¼ in. x ⅞ in. x ¾ in.	With 40 No. 9 x ¾ in. steel screws	Molding machine
104	--	**Lower-deck landings** (Fig. 290)	7037	A.	--	----------	--		Are screwed to the lower-deck roof on opposite corners with 8 No. 12 x 2 in. steel screws; the two of them being composed of:—	
104a	6	**Lower-deck landing-battens** (Fig. 290)	7039	A.	--	----------	--	21⅝ in. x 1⅞ in. x ⅜ in.	To which are screwed	Band saw and planer
105	20	**Lower-deck landing-slats** (Fig. 290)	7038	A.	--	----------	--	3 ft. 2¼ in. x ⅞ in. x ¾ in.	With 52 No. 9 x ¾ in. steel screws	Molding machine
									The work preparatory to painting the whole of the outsides except the posts can now be undertaken as follows:—	
									1st and 2d days—One coat of lead thinned with turpentine; a little oil is added (very small amount for iron-work) and a little dryer laid all over. 3d day—Fill all holes and depressions with putty. 4th day—Scrape in all iron work with a preparation in paste form of keg lead, dry lead, whiting, gold size and rubbing varnish. 5th day—Apply a coat of roughstuff. 6th day—Rub the roughstuff to a smooth surface. 7th day—Apply a coat of ground color tint. The interior and posts are treated with a coat of wood filler, a coat of white shellac, one of coach rub varnish and one of coach finish varnish left in gloss, 24 hours between each coat.	
									The cars are now ready for their platforms. *See Table No. 38, Con. No. 106 and Plate X.*

LEGAL NOTES AND COMMENTS

Edited by J. Aspinwall Hodge, Jr., of the New York Bar*

The Statute of Limitations and the New York Elevated Railroad Litigation

The history of the litigation against the elevated railroads of New York for damages and for injunctions, or for damages in lieu of the latter, on account of the taking of the easements of light, air and access from the owners of property abutting on the road, has reached, during the past year or two, a new stage.

Most of the elevated railroads now operating in the city of New York were opened during the years 1878, 1879 and 1880, and thus twenty years have now elapsed and the question arises as to whether or not, where no claim has been made upon the road and no action has been brought, the road has not acquired title to the easements of light, air and access by prescription or adverse possession.

During the first decade of the twenty years, that have elapsed, very little was accomplished on behalf of the property owners in the courts; but, during the last decade, the litigation has been fierce and active, and is probably unparalleled in the history of English or American law, both as to the number of actions, the variety of legal questions involved and the amount recovered against a single defendant. The recoveries have ranged from a few dollars a foot to nearly $2,500 per foot—the latter price having been awarded in two actions brought against the road by the respective owners of the two bank properties on the corner of Wall and Pearl Streets, extending along Pearl Street for a distance of about 80 feet,—the judgments for alternative relief and past damages aggregating nearly $190,000.

In these actions the six years statute of limitations has been held to apply and to prevent the recovery of past damages for more than six years prior to the beginning of the action. The ten years' statute of limitations has been held to have no application to the recoveries. Now that the twenty years have elapsed the question of title in the defendant road, of the easements by adverse possession, must soon be passed upon by the courts.

Already it has been presented, but the court has never been obliged to definitely pass upon it, as it may now be presented. It has arisen because the old Greenwich Street Road, which ran where the lower part of the Ninth Avenue Road now runs, was opened in 1869, ten years before the present system was put into operation. It was at first operated with an endless chain or cable, stationary engines being situated under ground at Cortlandt, Franklin, Bethune and Twenty-Second Streets. There were but two stations. A couple of years later one dummy and three cars were operated, and additional stations were opened from year to year, and engines and cars added, the increase being very gradual, until in the year 1877 the line was operated from Fifty-Ninth Street to South Ferry with twenty-one engines and thirty-five cars. This was superseded by the double track of the present Ninth Avenue line, which was opened on May 1, 1880.

In various suits brought against the road by property owners in Greenwich Street after the year 1889 (that is, twenty years after the opening of the original single-track cable road), the counsel for the Manhattan Railway Company urged that the road had acquired the easements of light, air and access by prescription, having been in adverse possession of them for twenty years.

But it was at once pointed out and afterward maintained by the courts through the Court of Appeals that the rule is unvarying and long established that, where title by prescription is claimed, it must be shown by the claimant that he has been in possession, not only, of a part but of all, that he claims, continuously, for the entire period of twenty years, and that this rule applied to the Greenwich Street cases. He cannot even claim, as a partial defense, title to that part of the property or easement which he has had for twenty years, but his defense is thrown out of court, if it be shown, that he has taken more, after the twenty years began to run, than he had at the beginning.—(*American Bank Note Co. vs. El. R. R., 129 N. Y., 252; Prentice vs. Geiger, 74 N. Y., 341.)*

This was manifestly the case on Greenwich Street, and on the whole line from South Ferry to Fifty-Ninth Street, for the light, air and access taken by the original structure of what was known as the "one-legged road" was very much less than that taken by the structure as it was enlarged, or rather, rebuilt, in 1879 and 1880.

The Second Avenue line was opened to Sixty-Fifth Street March 1, 1880, and to the Harlem, Aug. 16, 1880.

The Third Avenue line was opened to the Grand Central Depot, Aug. 26, 1878, and little by little was opened to the Harlem by Dec. 30 of the same year.

The Sixth Avenue line was opened to Fifty-Eighth Street June 5, 1878, and little by little was extended through Fifty-Third Street to 155th Street and Eighth Avenue by Dec. 1 of the following year.

To anyone who is familiar with the increase of traffic upon the elevated railroads in New York it does not need much legal acumen after a careful consideration of the facts and of the law which we have already given, to see that a strict application of the law to the facts as they have occurred since 1879 will necessarily lead to the conclusion that there are very few pieces of property in the city of New York where the road can successfully claim title by prescription.

For ever since the opening of the present system there has been a constant increase in all the branches and sections of the system in New York, not only in the number of stations, but in the number of engines and cars, and hence in the number of trains. Not many years ago the station platforms were lengthened so as to accommodate trains of five cars, in place of three and four, which formerly were the rule. Heavier engines have been built and are now universally used. Tracks are heavier, and in a large portion of the city a third track has been built. The amount of light and air and access which is kept from the property owner by the structure itself has been increased in many parts of the road by the increase in the size and number of the girders and in many cases by putting solid, in place of latticed girders. Along a large portion of the road a third track has been constructed, and express trains operated upon it.

Each and every one of these alterations tend to increase the amount of light and air and access of which the property owner is deprived. The damage done him by noise has been increased.

It has been held that where a person claimed adverse possession of the right to pollute a stream of water with sewerage, claiming that he had been possessed of the easement for twenty years, and where it was shown that pollution was gradually increased during the twenty years, he cannot maintain any title by prescription.—(*Goldsmidt vs Tunbridge, 1 Eng. L. R. Eq., 160.)*

According to the sworn testimony of the highest officials

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

of the road the limit of the train capacity of the present structure has been reached. Without increasing the number of tracks at present existing the road cannot run more trains than it is running to-day; certainly, not during the crowded hours, which is the only time when more trains are needed.

Thus far we have assumed that title by prescription of the street easements can be secured by a company operating an elevated railroad, provided they operate it without increasing the burden upon it, continuously, for twenty years or more under an adverse claim of right. But there is very serious doubt in the minds of a large portion of the legal fraternity as to whether street or highway easements can be acquired by prescription at all, however uniform, however continuous, and however long continued may be the occupation. They point out that each act of the road operated without title to the easement is a tort in the form of a trespass, and gives the right to an action, and these recurring rights are only barred by a six years' statute of limitations, and that these same acts can be enjoined in a suit of equity whenever they occur, whatever may be the frequency and history of past acts of a similar character. There are authorities which would seem to support their contention, but if the proposition is as clear to the courts, as it appears to us, that the elevated railroad has taken more and more of the easements as each increase has been made in the burden imposed upon their structure, then the question as to whether title can be procured by prescription where the burden is not increased for twenty years will not arise for many years to come.

In many cases adverse possession could not in any event be successfully set up, for where the property has been owned by infants or others laboring under similar disability, the period of such disability is not allowed as part of the twenty-year period. H.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

ALABAMA.—Carriage of Passengers—Rules of Carrier—Ejection of Passenger—Question for Jury—Instructions.

1. A rule of a street railway company requiring colored passengers to occupy seats in the front end of its cars, and white passengers to occupy seats in the rear end, is a reasonable regulation.

2. When the existence of a rule of a carrier requiring white and colored passengers to occupy different parts of the same car is established by the evidence, and its violation is shown, the reasonableness of the rule is purely a question of law for the court, and not a mixed question of law and fact.

3. Where plaintiff, a passenger on an electric car, alleged and proved that the ejection from the car was committed jointly by the conductor and motorman, it was not error to charge the jury to find for defendant if they believed from the evidence that the motorman did not aid or assist in ejecting her.—(Bowie vs. Birmingham Ry. & Elec. Co., 27 So. Rep., 1016.)

DELAWARE.—Constitutional Law—Obligation of Contracts—Corporations—Revocation of Corporate Charter or Rights—Street Railways—Traffic Agreements—Franchises—Right to Question—Injunction—Equity—Estoppel.

1. Const. 1831, art. 2, sec. 17, authorizes the Legislature to incorporate "with a reserved power of revocation by the Legislature." Held, that such provision became a part of the charter of corporations subsequently formed, and that the Legislature might exert that power at any time.

2. The provision in Const. 1831, are 2, sec. 17, authorizing the Legislature to incorporate "with a reserved power of revocation by the Legislature," permits the withdrawal of a single right or privilege without revoking the whole franchise.

3. The revocation contemplated under such clause may be either direct or by necessary implication by the passage of an act necessarily inconsistent with some right or privilege possessed by an existing corporation.

4. An act giving a street railway company a franchise to construct lines in certain streets of a city, in which another existing corporation has been granted the exclusive franchise, impliedly revokes such exclusive privilege under the power reserved in the Legislature by Const. 1831, art. 2, sec. 17.

5. An act providing for the construction of a street railway from outside the city required that it be constructed to the boundary line of the city at U Street, and that it should be completed in a certain time. A supplement to such act provided that the road might be extended from a point at which the railway intersected the boundary line, through and along G Avenue, etc., and extending the time for completion. The road, as actually built, did not run to the intersection of the boundary line at U Street, but directly to G Avenue. Held, not a sufficient compliance with the conditions of the charter, and the rights of the corporation thereunder were forfeited, although a strict construction of the statute would necessitate an acute angle in the road.

6. An exclusive right granted to a street railway company to operate its line in a city is such a property right as will entitle it to raise by injunction the question of forfeiture, by failure to perform the conditions, of the charter of a company, which is granted the right to build a street railway in certain streets of the same city.

7. A franchise to a street railway corporation giving it exclusive right and privilege of locating, constructing, operating, and maintaining a city railway within the limits of a city, designating the route of the road, and giving the further privilege of building anywhere within the city, on condition of obtaining the consent of the City Council, is an exclusive franchise as to all streets in the city.

8. Grants of an exclusive franchise to a street railway company to operate a "city railway," which provides, among other things, that steam power shall not be used unless with consent of the Council, and that bells shall be attached to the horses, does not mean, because of the use of such words, and of the fact that horse power was the only power then in use, that the motive power shall be limited to steam or horse power, or prohibit the use of electricity, so that the grant of a right to another company to use electricity would not be a violation of the franchise.

9. A charter for an electric railway company authorized it to make a traffic agreement with a street railway company in an adjacent city, stipulating that the former company should not build its tracks within the limits of said city. Subsequently the former company was granted a franchise to build a street railway line in said city. Held, that such a traffic agreement was ultra vires and void, as being in restraint of competition.

10. A court of equity will not enforce by injunction a traffic agreement between two railway companies by which one of them is restrained from competing with the other.

11. A traffic agreement between two street railway companies, by which one is restrained from competing with the other, does not estop the latter to question the corporate existence of the former, such question not arising out of the contract.—(Wilmington City Ry. Co. vs. Wilmington & B. S. Ry. Co., 46 Atl. Rep., 12.)

NEW JERSEY.—Taxation—Assessment—Correction—Real Estate—Certiorari.

1. A mistake of an assessor in listing as personal, property described in terms showing it to be real estate, may be corrected, even after the duplicate has been delivered to the collector.

2. An electric street railway is real estate, within the tax laws.

3. When it is sought, on certiorari, to set aside a warrant for sale of real estate for taxes on the ground that the prosecutor is a purchaser in good faith, against whom, as such, the tax lien has been lost by failure to make timely return to the County Clerk, and the proof of such status is not satisfactory, the writ should be dismissed, and the prosecutor be left to his defense against a possible purchaser at the tax sale.—(State [Newark & H. Traction Co., Prosecutors] vs. Mayor, etc., of Borough of North Arlington et al., 46 Atl. Rep., 568.)

NEW YORK.—Repeal of Statute—Effect—Pending Cases—Appeal—Street Railways—Consent of Abutting Owners—Crossing Railway.

1. Under Laws 1892, c. 677, sec. 31 ("Statutory Construction Act"), providing that the repeal of a statute shall not affect or impair rights accrued or acts done before it takes effect, a pending appeal, in proceedings by a street railway company to acquire the right to cross the tracks of a railway company at a point where they intersect a highway on which the street railway tracks are laid, was not affected by the enactment of Laws 1897, c. 754, which made changes in the procedure to acquire such right.

2. On appeal from the decision of a referee, the appeal will not be disposed of on a theory not presented to the referee.

3. Under Laws 1890, c. 565, sec. 91, providing that street railways shall not be built in the highways of a town without the consent of the town boards; and sec. 12, providing for the procurement of the right of one road to cross the tracks of another, and for determining the manner thereof and the compensation to be paid therefor—a street railway company owning a road which is to be built from one town into another, which has obtained the consent of the authorities of a town within which a crossing is to be made to the use of the highway of such town by the street railway com-

pany, may maintain an action to acquire the right to cross the tracks of a railway company which intersects the highway on which the street railway company's tracks are laid, though it had not the consent of the other town into which it proposed to build its road.

4. Under Laws 1890, c. 565, sec. 91, providing that a surface street railway shall not be built on any street or highway without the consent of the owners of one-half in value of all the property abutting on the street, a consent by the requisite number of the abutting property owners given to certain promoters of a proposed corporation, their assigns and legal representatives, to the construction of a surface road, which is subsequently assigned to a corporation, is sufficient to authorize the construction of a surface street railway in the highway by the assignee, and a railway over whose tracks the street railway company has instituted proceeding to procure a right to cross at a point where they intersect the highway cannot question the sufficiency of such consent.—(Geneva & W. Ry. Co. vs. New York Cent. & H. R. R. Co. Same vs. Fall Brook Ry. Co., 57 N. E. Rep., 498.)

NEW YORK.—Transfer of Passengers—Action—Complaint.

1. Under Laws 1890, c. 565, sec. 101, providing that no corporation operating a street surface railway under that chapter or chapter 252 of the Laws of 1884, shall charge more than 5 cents for one continuous ride from any point on its road, or on any line or branch operated by it or under its control, to any other point thereof, a complaint in an action by a passenger on a surface railway line against the company for its refusal to transfer him from one of its lines to a connecting line, which does not allege that the company was organized under the provisions of Laws 1890, c. 565, or Laws 1884, c. 252, is demurrable.

2. Same. Under Laws 1890, c. 565, secs. 103-105, providing that street surface railways may contract for the use of any other company's road, and providing that every such corporation entering into such a contract shall carry passengers between any two points on the railroads embraced in such contract for a single fare, a company leasing another connecting company's road, and operating it, is not bound to transfer a passenger riding from a point on the defendant company's original line to a point on the leased line where it intersects a line subsequently leased by defendant, to the line so subsequently leased, since the three roads are not united by one contract.—(Mendoza vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 745.)

NEW YORK.—Contract—Construction—Breach.

1. An agreement between plaintiff's assignor and defendant reciting that defendant should, on foreclosure sale of certain property, furnish the money required to purchase the property, "at such price as may hereafter mutually be agreed upon," will be construed as calling on each party to use reasonable efforts to agree on a price which should be bid for the property; and, if defendant refused to make such efforts, such refusal would be a breach of his contract.

2. Same—Correspondence—Construction. The effect to be given to correspondence between parties, introduced for the purpose of determining whether or not there has been a refusal to comply with the terms of a contract, is one of law, for the court, and should not be submitted to the jury.

3. Same. Defendant agreed with plaintiff to furnish the money required to purchase certain property at foreclosure sale, at a price thereafter to be agreed on. Prior to the sale, defendant's directors passed a resolution declaring that not over a certain sum should be bid, and transmitted a copy of the resolution to plaintiff. Plaintiff, by letter, stated that he was not satisfied with the amount fixed. Defendant answered that it stood ready to carry out the original agreement. Plaintiff wrote that defendant could not, if necessary to secure the property, bid less than an amount stated, which was greatly in excess of the amount fixed by the directors. The contract contemplated the reorganization of the company owning the mortgaged property, of which plaintiff owned a majority of the stock. The letter stated that the essential part of the agreement was that defendant should buy at the sale for the lowest amount practicable, and that the details of the reorganization were the only matters left to subsequent mutual agreement. Held, to show a refusal by plaintiff's assignor to negotiate as to the price to be paid, and not to show that defendant had refused to negotiate, or had arbitrarily fixed a limit for the amount which it would bid.—(Smith vs. United Traction & Elec. Co., 63 N. Y. Suppl., 665.)

NEW YORK.—Transfers—Ejectment of Passengers—Tort.

1. Where plaintiff was ejected from one of defendant's cars, and accused of having picked up his transfer in the street, because the conductor who issued it had punched it to read 2:40 p. m. instead of 3:40 p. m., by mistake, plaintiff was entitled to sue in tort for damanges for the expulsion, and the humiliation and injury to his feelings caused by the insulting remarks of the conductor, and was not limited to an action for the breach of his contract for transportation.

2. Same—Nonforcible Expulsion. That plaintiff left one of the defendant's cars in the middle of the block, at the command of the conductor, without waiting to be forcibly expelled, did not prevent him from suing for being wrongfully expelled.

3. Same—Exemplary Damages. Where plaintiff was put off of one of the defendant's street cars, in the mud, at the middle of the block, and accused of having picked up his transfer in the street, because the conductor who issued it had erroneously punched it to read 2:30 p. m. instead of 3:30 p. m., he was not entitled to recover exemplary damages.—(Eddy vs. Syracuse Rapid Transit Ry. Co., 63 N. Y. Suppl., 645.)

NEW YORK.—Highway — Unlawful Use — Action — Parties Plaintiff. An action to enjoin a corporation from constructing a street railway on a highway, and to compel it to remove a track already laid without lawful authority and to restore the highway to its former condition, can be brought in the name of the town, under Highway Law, sec. 15, authorizing the highway commissioners to bring an action in the name of the town "to sustain the rights of the public in and to any highway in the town."—(Town of Eastchester vs. New York, W. & C. Traction Co., 63 N. Y. Suppl., 1032.)

NEW YORK.—Parties—Corporations and Stockholders.

1. The stockholders of a corporation are neither necessary nor proper parties to an action to enforce an agreement of a third person to hold an assignment of a franchise for the benefit of the corporation, where the corporation does not refuse to sue; they not being persons having an interest in the subject of the action and in obtaining the judgment, within Code Civ. Proc., sec. 446.

2. Demurrer—Misjoinder of Plaintiffs. A complaint is demurrable because a plaintiff is neither a necessary nor proper party; Code Civ. Proc., sec. 488, subd. 5, permitting a defendant to demur on the ground that there is a misjoinder of parties plaintiff.—(Havana City Ry. Co. et al vs. Ceballos et al, 63 N. Y. Suppl., 417.)

WASHINGTON.—Taxation — Property Subject — Corporate Franchises—Assessment—Board of Equalization—Valuation.

1. Corporate franchises are taxable.

2. A board of equalization, which received affidavits and all information tendered, and heard arguments of counsel in support of an application for a reduction of assessments, cannot be said to have arbitrarily refused to receive testimony in support of such application, merely because it failed to pass on an offer on the part of one of the property owners to swear a witness, who afterward stated his views, together with others having knowledge of the values of the properties assessed.

3. It is only when taxing officers have acted maliciously, fraudulently, arbitrarily, or oppressively, that their determination of values will be disturbed.

4. A corporation had notice that its franchises were assessed, where the assessor, before returning the roll to the board of equalization, at a time when he could lawfully make corrections, inserted the word "franchises" in the column entitled "Other Property," without changing the valuation, and its officers subsequently appeared before the board and applied for a reduction of the assessment.—(Spokane St. Ry. Co. vs. Spokane County, 60 Pac. Rep., 132.)

LIABILITY FOR NEGLIGENCE

MICHIGAN.—Liability for Negligence — Injuries — Bicycle Rider—Contributory Negligence. Plaintiff was injured by a street car when attempting to cross the track on a bicycle. He was going at the rate of four to six miles an hour, and did not look for the car till he was on the track. If he had looked, he could have seen the car in time to have stopped or turned aside. Held, that the plaintiff could not recover for the negligence of the company in running the car at an excessive speed and not ringing the gong, as his own negligence contributed to the injury.—(Bennett vs. Detroit Citizens' St. Ry. Co., 82 N. W. Rep., 518.)

NEW YORK.—Appeal—Review—Collision—Admissibility of Evidence—Instructions—Province of Jury—Negligence—Pleading—Special Damages.

1. An objection that certain evidence was immaterial and irrelevant as no part of the negligence charged, and as not showing negligence, did not raise the objection that the evidence, if it showed negligence, was not such negligence as contributed to plaintiff's injury.

2. Evidence of omission to sound a street-car gong at a place where the law did not require it to be sounded is admissible as a part of the history of the transaction, and as bearing upon the degree of care exercised by the street-car employees, and upon the question of plaintiff's contributory negligence.

3. Sufficiency of evidence to sustain a verdict cannot be reviewed in the Court of Appeals, where the decision below was unanimous.

4. An instruction that, if the jury believed that an accident occurred as described by plaintiff's witnesses, then plaintiff is entitled to recover, is not open to the objection that it prevents the

jury from construing the evidence and determining the facts established; such charge being equivalent to an instruction that, if the facts claimed by plaintiff were established, she was entitled to a verdict.

5. An objection that instructions to find for plaintiff if the jury believe that an accident occurred, as described by his witnesses, is not open to the objection that it prevents the jury from construing the evidence, where another instruction gives the jury the same power if witnesses for defendant are believed.

6. Testimony that plaintiff's "heart was affected, that the dorsal muscle on the right side was paralyzed, and that she had trouble with her menstruation, suffered from vertigo, and had curvature of the spine," is not admissible under a complaint, alleging that plaintiff received "severe and painful contusions to her head, body and arms, and lacerated her scalp, and whereby she sustained severe nervous shock and concussion of the brain, and injured her eyesight, and she was for a time rendered unconscious, and she thereby sustained permanent injuries, and was injured for life."—(Kleiner vs. Third Ave. R. R. Co., 56 N. E. Rep., 497.)

NEW YORK.—Collision at Crossings—Evidence—Negligence—Instructions—Presumption.

1. In an action to recover for injuries by a collision of two street cars at a crossing, the fact that one of the cars was first on the crossing is not conclusive proof that such car had the right of way, but, in the absence of evidence as to the relative position and speed of the two cars as they approached the crossing, it constituted evidence from which the jury might have inferred that the car first on the crossing was entitled to precedence; and that the car first on the crossing was nearly over when struck is admissible to throw light on the relative position of the cars.

2. In an action to recover for injuries by the collision of two street cars at a crossing, an instruction that the accident raised a presumption of negligence against the company on whose car plaintiff was not a passenger, requiring an explanation on its part, is erroneous, since, not being the carrier, it was bound only to exercise ordinary care in the management of its cars, and, as there were two actors in the collision, it might have been due entirely to the fault of one party, and not at all to the fault of the other.

3. The mere fact of the accident raises a presumption of negligence on the part of the carrier, which makes it incumbent on the company carrying the passenger injured to show that it occurred without negligence on its part.

4. There was but little evidence as to how the accident occurred. It appeared, however, that the car in which plaintiff was a passenger had nearly crossed over the other company's track when it was struck by its car. Held, that it was error to charge, as a matter of law, that the company on whose line plaintiff was a passenger had offered no explanation of the cause of the accident, to rebut the presumption of negligence arising from the fact of the accident, since the relative position of the cars at the time of the accident should have been considered in determining whether or not the company was negligent.

5. In an action against two street railway companies, jointly, to recover for injuries sustained by reason of a collision at a crossing, an instruction that defendants were liable in case the jury should find that "the collision can be attributed to the want of reasonable care on the part of defendants" is erroneous, as their liability depends on whether or not, as a fact, it was attributable to their negligence.—(Londoun vs. Eighth Ave. Ry. Co. et al., 56 N. E. Rep., 988.)

NEW YORK.—Attorney and Client—Lien of Attorney—Enforcement as Against a Defendant—Practise. The practise of forcing an attorney's lien for his compensation, given by Code Civ. Pros., sec. 66, as against a defendant, who has settled with his client without his knowledge, by action, and not by motion, is not affected by the amendment of 1899, providing that the court, "on petition of the client or attorney, may determine and enforce the lien," as the amendment does not, in terms, relate to a defendant, but merely aims to formulate a practise applicable as between an attorney and his client.—(Rochfort vs. Metropolitan St. Ry. Co., 63 N. Y. Suppl., 1036.)

NEW YORK.—Negligence—Extent of Injuries—Evidence.

1. Where plaintiff, an actress, suing for injuries sustained, testified that on joining her company, some weeks after the accident, she was so ill as to seldom be able to attend rehearsals, and was under a doctor's care all the time; that her manager well knew how ill she was; and that she was finally compelled by sickness to stop work—it was error to exclude testimony of the manager as to what he had observed as to her physical condition during that period.

2. Same. Where plaintiff had testified that she was forced to disband her theatrical company through ill health due to injuries sued for, and not because of her incompetency as an actress, it was error to exclude the testimony of her manager as to why the company was disbanded.—(Farrell vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 709.)

NEW YORK.—Negligence—Instructions.

1. In an action for injuries caused by plaintiff's wagon colliding with a street car while he was driving across defendant's tracks, an instruction that if, just before the accident, the wagon was driven alongside the track and it was turned into the track in front of the car, the verdict must be for the defendant, was properly refused, since the turning into the track might have been far enough in front of the car to have given the gripman ample time to stop the car and prevent the accident.

2. Same — Special Damages — Allegation — When Necessary. Where injuries for which recovery is sought do not necessarily result from those described in the complaint, they must be alleged as special damages; and an injury to plaintiff's eye could not be recovered for on an allegation of injury to the head and brain, since it did not necessarily result therefrom.—(Geoghan vs. Third Ave. Ry. Co., 64 N. Y. Suppl., 630.)

NEW YORK.—Excessive Damages—Personal Injuries. Plaintiff, a teacher, was injured by the sudden stopping of defendant's street car, on which she was a passenger; the injury being a dislocation of a cartilage in each knee, with other injuries to her body. She expended $1670 for medical services, and was confined to her bed about ten weeks. At the time of the trial, eighteen months after the accident, she could not go up and down stairs without pain, and, in consequence of her condition, had to give up her position of general superintendent in a school. Held, that a verdict of $15,000 should be set aside as excessive.—(Kraemer vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 619.)

NEW YORK.—Malicious Prosecution — Evidence — Judicial Proceedings. An action for malicious prosecution will not lie against a defendant for having illegally arrested plaintiff without a warrant, and having brought him before a police court, where he is discharged without the filing of a complaint; an essential element of malicious prosecution being a commencement of judicial proceedings.—(Barry vs. Third Ave. R. Co., 64 N. Y. Suppl., 615.)

NEW YORK.—Damages—Evidence—Pleading.

1. Where the complaint alleges that plaintiff received a "wound at the right upper angle of the forehead; also a fracture of the skull, concussion of the brain, and a fracture of the nasal bone," he cannot introduce evidence of hysteric epilepsy, unless that condition resulted immediately and necessarily from those injuries.

2. Special Damages. Where it appears from the evidence that the hysteric epilepsy from which plaintiff suffered did not result immediately and necessarily from the injuries set out in his complaint, a motion to strike out the evidence of this condition on the ground that plaintiff has not pleaded it as a basis for special damages should be sustained.—(Ackman vs. Third Ave. R. Co., 65 N. Y. Suppl., 97.)

NEW YORK.—Personal Injuries—Earning Capacity—Excessive Damages.

1. Where the evidence in a personal injury case does not show that plaintiff's injuries have, or will, affect his earning capacity to any great extent, a verdict for $5000 is excessive.

2. Same—Stipulation for Reduction—New Trial—Plaintiff's Option. Where a verdict for personal injuries is found excessive, plaintiff will be given the option to stipulate for a reduction of the recovery to an amount deemed proper by the Appellate Court, or to have the order of the trial court denying defendant a new trial reversed.—(Kaplan vs. Metropolitan St. Ry. Co., 65 N. Y. Suppl., 91.)

NEW YORK.—Personal Injuries—Negligence—Trial. Plaintiff (a woman sixty years of age), before starting to cross the street in the middle of a block, stopped and looked, and saw that there was no approaching car nearer than one in the next block, and that it was slackening its speed at the crossing. There was evidence tending to show that the motorman had applied the power at the corner, that the speed increased until plaintiff was struck, that no bell was rung, and that the motorman's head was turned, and he was talking with a person inside the car. Held, that whether plaintiff exercised reasonable care, and whether defendant was negligent, should have been submitted to the jury, and it was error to nonsuit plaintiff.—(Killen vs. Brooklyn Heights R. Co., 62 N. Y. Suppl., 927.)

NEW YORK.—Injuries—Defective Track—Proof. Where the complaint, in an action against a street railway company for an injury resulting from the defective condition of a certain part of its track, alleges that such road was operated by the defendant company, and the answer admitted the operation thereof, it was error to dismiss the complaint because the evidence failed to show that defendant was prima facie liable for the defective condition of the track.—(Schnell vs. Metropolitan St. Ry. Co., 64 N. Y. Suppl., 67.)

The International Tramways and Light Railways Exhibition

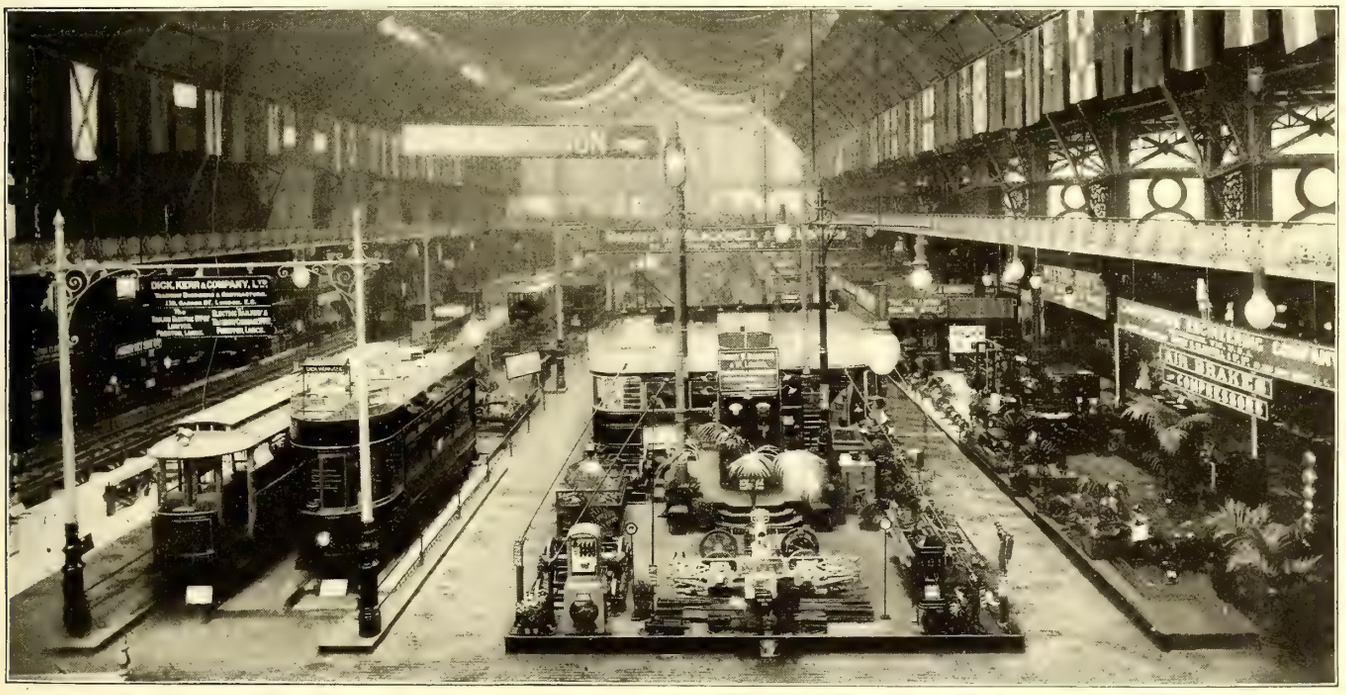
(From Our Own Correspondent.)

The opening of the International Tramways and Light Railways Exhibition at Agricultural Hall, London, on June 27, has already been chronicled in these columns, but the lateness in the month of the opening date prevented the publication in the July issue of any of the papers presented, or of any views of the exhibits. The exhibition, which was under the patronage of many prominent railway managers and municipal corporation officials in the United Kingdom, was the largest and most successful event of the kind ever held in Great Britain, and great interest was taken in it, as the large attendance testified.

THE EXHIBITS

From the different views of the exhibition which are published it will be seen that the large hall was amply filled with exhibits of cars, overhead-line equipment, track, generators, motors, etc.; in fact, all that goes to make a successful tramway installation.

THE BRITISH WESTINGHOUSE ELECTRIC MANUFACTURING COMPANY, LTD., had a space which extended the whole length of the hall, a little more than 300 ft., in which the company had erected a perfectly equipped conduit system, on



GENERAL VIEW OF EXHIBITION FROM ENTRANCE

which was a very handsome car, built to the company's designs, by George T. Milner & Company, of Birkenhead. The conduit was all above the floor, and its working parts were readily examined by those interested. The power for operating the car was furnished by a Westinghouse three-cylinder gas engine, rated at 112 B. H. P., direct coupled to a 75-kw, 500-volt Westinghouse generator. A fine panel switchboard, fitted with the usual switches, circuit workers and instruments controlled the circuits. The car was equipped with two No. 49 multipolar motors, fitted with the usual Westinghouse controller. The car was also equipped with an electromagnetic brake (Newell patents), which, in addition to braking the wheels, also magnetically grips the rail, and by an interesting system of levers, the effect on the wheel rims is not changed by the application of the track brake. The car was a handsome example of the most modern British pattern, constructed by George T. Milner & Company, and was mounted on Brill trucks. It was double-decked and could seat twenty-eight persons inside and thirty-six outside. The car was equipped with an electric-bell system for the passengers, inside and outside, and was equipped also with electric heaters. The working of the electric brake was also shown on other models exhibited, and there were also Baldwin trucks for light railway work. The Westinghouse electro-pneumatic control system for trains of cars was also shown by a full size working model of two cars equipped with complete apparatus, showing in train work the advantages of distributing the power among several motors throughout the train. It only remains to say that the car on the conduit system made regular trips during the whole period of the exhibition without mishap, and was generously patronized, nearly all visitors having a ride on it before leaving the hall.

DICK, KERR & COMPANY, THE ENGLISH ELECTRIC MANUFACTURING COMPANY, AND THE ELECTRIC RAILWAY & TRAMWAY CARRIAGE WORKS, LTD.—Moving to the right the next exhibit was that of the three companies mentioned, which was in the nature of combined exhibit, Dick, Kerr & Company acting as selling agents for the other two, and showing a most comprehensive collection of examples of permanent way construction and electric tramway rolling stock and accessories. Cars naturally formed a large part of the exhibit, four different types being shown, as follows: 1. Bogie vestibuled top seat for heavy city service, fitted with a Bellamy reversed staircase, and capable of seating sixty-four passengers. The car was mounted on Brill maximum traction trucks, and the motors and controllers were by the English Electric Manufacturing Company. 2. Bogie cross-bench car for high-speed summer suburban service, with a seating capacity of fifty-five passengers, mounted on equal wheel bogies, and with four-motor equipments, and equipped with air brakes and axle-driven compressors. 3. Four-wheel top-seat car of the improved Preston type, fitted with Bellamy reversed stairway, with a seating capacity of fifty-six passengers. 4. Four-wheel single-deck car, equipped with air brakes, with axle-driven compressor, and having a capacity of twenty-six passengers. Needless to say all these cars were built by the Electric Railway & Tramway Carriage Works, of Preston, and the whole electric equipment was supplied by the English Electric Manufacturing Company, of Preston. All were extremely well finished and thoroughly handsome samples of what the company is daily doing at its extensive Preston works. In addition to the cars a truck was shown fully equipped with motors and air brakes, the motors, controllers, etc., being of the Short system, and the brakes and the compressors being on the standard air-brake system. A number of samples of tramway permanent way was shown, varying from rails weighing 96 lbs. to the yard, with Dicker patent continuous joints, to rails weighing only 65 lbs. to the yard, spiked to 9 ft. x 9 ins. x 4½ ins. timber ties. Special truck work was also shown with points 7 ft. 6 ins. long, built from rails weighing 83 lbs. per yard, and various rail sections and rail joints added to the completeness of the exhibit. Finally the company showed a number of standard designs of poles, brackets, and all the necessary details for overhead erection, making a most complete and artistically arranged exhibit.

ROBERT W. BLACKWELL & COMPANY, LTD.—In designing their exhibit Blackwell & Company evidently intended to show a sample of every device which enters into the construction of an electric tramway, only omitting engines and power houses, these being substituted, however, by admirable photographs and working drawings. Commencing with the permanent way, they

showed some samples of manganese steel frogs, switches and crossings, this metal being chosen on account of its extraordinary toughness and hardness, being particularly suitable for this class of work, which is subjected to excessive tear and wear. The "Chicago" rail bond was also shown in profusion, and also the "Crown" bond, which, it is claimed, is an improvement on the other. The Edison-Brown plastic bonds were also shown in an exhibit by themselves, with Harold P. Brown in attendance. Four trucks of the Peckham type were shown, namely, the "Standard" for heavy 18-ft. to 20-ft. cars; an "Extra Long" truck, with 30-in. wheels, the whole designed specially for long heavy cars; a swing bolster "Maximum Traction" truck, fitted with the latest pattern side frames, and a short wheel-base swing bolster truck, designed to take successively curves of 30-ft. radius or less. On this last truck was displayed the Price momentum friction brake, which is so constructed that it utilizes the energy of the moving car for power. A very complete exhibit of air brakes was also shown on the adjoining stand of the Christensen Engineering Company, of Milwaukee. The Hipwood-Barrett fender attracted a good deal of attention, though it failed to secure the prize offered by the association, who awarded it to an ordinary life guard. Four poles were erected at corners of the exhibit, each being different, one being a center pole and bracket for flexible suspension, a side pole and bracket for flexible suspension, an ordinary side pole and bracket, and Blackwell's standard pole and bracket. Samples of trolley wire and Ætna insulators were shown, as also two samples of conduits, one being of historic interest, having been laid by Mr. Blackwell in Allegheny City, Pa., in 1887. Various trolleys were shown, including the "Pivotal" Boston trolley, the Standard trolley, the Dwarf trolley, the Winslow trolley, and also the "Southampton" and "Dublin" types of inclosed spring trolleys. Switches and circuit breakers, junction boxes, P. & B. electrical compound incandescent lamps, and a trolley wagon took up most of the remaining part of the exhibit, though mention should also be made of the various steam devices shown, including the Bundy oil separator, patent steam traps, Siegrist lubricators, and a large number of specialties useful in electric power houses.

THE BRITISH THOMSON-HOUSTON COMPANY, LTD.—An excellent display of electric cars and various tramway devices was also shown by this company, who had an extensive space well located in the center of the hall. They showed a fully equipped car built by Hurst, Nelson & Company, of Motherwell, mounted on two Brill maximum traction bogie trucks, and equipped with two standard G. E. double motor rheostatic brake equipment. The car is fitted with the Hurst-Nelson reversed stairway, and with its open iron grill surrounding the outside seats, presented a very handsome appearance, as well as giving it the air of coolness. The other car was also built by Hurst, Nelson & Company, to the designs of J. Clifton Robinson, and was exhibited by the kind permission of the directors of the London United Tramways, Ltd., for which company the car was built. It had accommodation for thirty inside passengers and thirty-nine outside, and its interior was lavishly and luxuriously fitted up. The ventilators extend the whole length of the car, and electric push buttons are provided for the use of the passengers for communicating with the conductor. For the purpose of showing the electric equipment in detail, a standard Hurst-Nelson truck with extension springs was exhibited, on the axles of which were mounted two G. E. 58 motors, with inclosed gear cases, so arranged that the wheels were free to revolve, illustrating the complete control of the driving mechanism by the motorman. The motors were connected to a series parallel magnetic blow-out controller of the rheostatic-brake type, and showed the effectiveness of this method of electric braking. A number of automatic circuit breakers were also shown, as also resistance boxes, various trolleys, tramway recording wattmeter, electric heaters, feeder pillars, overhead material, magnetic blow-out lightning arresters, etc., etc. The company also showed a section of an underground conduit system, on which was mounted a truck equipped with contact plow, showing the method of raising and lowering the same in and out of the conduit. Altogether the exhibit was a most complete one, and showed in a clear manner the advances made in electric traction in the past few years. That it was appreciated was evidenced by the interest shown by the large number of visitors in constant attendance.

EXHIBIT OF THE BRITISH THOMSON-HOUSTON CO.

A. & F. MANUELLE, of London, showed a varied assortment of granites from their quarries at Aberdeen, Guernsey, Norway and Leicestershire, for paving purposes.

ALBION CLAY COMPANY, LTD., of Burton-on-Trent, showed some admirable samples of its stoneware conduits, arranged with circular ducts, provided with spigot and socket, and fitted with Stanford joints. The company also showed samples of its troughing for its solid system of laying cables, which is also made of stoneware, and formed with spigot and socket ends, and has, in addition, a longitudinal socket to admit of a cover being formed.

E. S. HINDEY, of London, showed some specialties in vertical boilers, horizontal steam engines, dynamos and pumps.

CHARLES CHURCHILL & COMPANY, of London, showed a most interesting and comprehensive collection of high-class American machine tools, weighing in all about 30 tons. These comprised planers, shapers, lathes, turret lathes, screwing machines, radial drills, boring mills, key-way cutters, universal milling machine, universal cutter grinder, track drills, track jacks, rail saws, rail benders, etc., etc.

ESTLER BROTHERS, of London, had a tastefully arranged booth in which they displayed hundreds of various samples of the well-known insulating material, "Ambroin." This material does not absorb moisture, nor does it deteriorate on exposure, and can be molded into any desired shape. It is used in all the overhead fittings exhibited by this company, which comprised a variety

of appliances used in the overhead construction for electric tramways. It has a very large use also in sparking shields and other insulating parts of controllers, controller handles, and, in fact, in almost any place where insulating material is used. They also showed some new forms of trolley standards for center or side running, and for top-seat or single deck cars. They showed, also, a trolley head of the swiveling type, fitted with a ball-bearing turntable, and also a number of samples of the Garton lightning arrester. A model of a conduit and surface contact system (Steudebach's combined) was also exhibited.

THE ROLLER BEARINGS COMPANY exhibited samples of roller bearings, as adapted to Peckham and Brill trucks, shafting bearings, trolley bearings, etc.

FREDERICK LELL exhibited some samples of steam separators, grease extractors, automatic exhaust valves, jet condensers, as well as a "Bemis" truck. He also showed some handsome photographs of the Ball & Wood engine.

EDWARD BENNIS & COMPANY, of Bolton, showed an interesting machine stoker and self-cleaning furnace at work. This furnace has been adopted by many of the tramway companies, as it raises steam rapidly, and any class of coal can be used.

VIEW OF EXHIBITION FROM REAR OF HALL

G. F. ZIMMER, of London, had on exhibition models of the Kreiss patent swinging conveyor, which, by means of vibrations, conveys coal or other material with a very small expenditure in power.

DOCKER BROTHERS, of Birmingham, showed some samples of varnishes and paints suitable for tramway cars.

THE KLEIN ENGINEERING COMPANY, of Manchester, exhibited models of its patent water coolers, used in conjunction with condensing engines at power plants. Oil separators were also shown, and a number of interesting photographs, showing Klein's counter-current jet condensers in course of erection at the Liverpool Corporation's new electric power house at Lister Drive.

LE CARBONE showed samples of carbon brushes, which are the principal specialty of this firm, as well as carbon-contact pieces, carbons for arc lamps, crucibles, primary batteries and a number of articles in use where carbon is a necessity.

THE OHMER SYNDICATE, LTD., exhibited a ticket-recording machine, which is 5¾ ins. square by 1¾ ins. deep, and weighs about the same as the ordinary ticket punch. It is intended to be worn by the conductor on a belt, is loaded with a roll of blank paper, has a time clock on its face, and can issue up to 3000 tickets if necessary. It adds the cash taken, records the number of passengers carried, and exposes the figures to the conductor and passengers.

TANGYES LIMITED, exhibited a portable hydraulic wheel press, tested to 50 tons, for putting on and taking off one railway wagon or tramcar wheel at a time, taking solid wheels up to 27 ins. diameter, and spoke wheels up to 36 ins. diameter. They also showed a hydraulic rail bender, manufactured by themselves, a gas engine, an oil engine and a steam engine, all in operation, and also showed a quick-speed governor for steam engines, and a useful lifting tackle.

THE JOSEPH DIXON CRUCIBLE COMPANY made an exhibit of graphite for lubrication, graphite pipe-joint compound, silica graphite paint, graphite greases, graphite resistance rods and graphite dynamo brushes.

THE ST. HELENS CABLE COMPANY, of Warrington, had a booth tastefully ornamented with samples of its various cables and insulated wires for traction and lighting purposes.

BABCOCK & WILCOX, LTD., of London, exhibited a handsome model of their well-known boiler to a scale of one-eighth. To describe this exhibit would be, therefore, simply to describe the B. & W. boiler, the model being complete in the smallest detail, and being one of a number which the company is now making for its numerous branch offices. The model also showed a Babcock & Wilcox patent superheater, consisting of solid drawn-steel tubes, expanded at the ends into wrought steel cross-boxes.

JOSEPH OWEN & SON, LTD., of Liverpool, had a unique exhibit, comprising samples of every variety of English and foreign timber used in the bodies of tramcars and other vehicles, of which this company makes a special feature.

THE WORTHINGTON PUMPING ENGINE COMPANY, LTD., of London, showed a small compound pressure feed pump, a type largely used in power stations where high pressure is carried. The company also showed a number of photographs and white prints of Worthington pumps, heaters, and of various types of its self-cooling condenser.

S. Z. DE FERRANTI, LTD., of Hollinwood, Manchester, showed, in a neatly decorated space in the entrance to the hall, and not in the main hall proper, one of their well-known 50-light rectifiers, and a number of their high-tension oil fuses. They also showed a number of extremely handsome photographs, beautifully executed, of their engine and dynamo combination, both vertical and horizontal, central station switchgear, high-tension switchgear, high-tension dynamo switchgear, high-tension oil break switch, maximum capacity 500 amps. at 2000 volts, high-tension plug fuses and blocks, open type rheostats, and a number of other specialties. These photographs were of large size and well arranged, and made quite an interesting exhibit.

THE VACUUM OIL COMPANY, of Rochester, had an elaborate exhibit, under the management of its London office, of its specialties, such as cylinder and valve oils, engine, dynamo and shafting oils, and patent automatic sight-feed lubricators.

THE LORAIN STEEL COMPANY showed some interesting samples of track construction, such as has been used in Newcastle-on-Tyne, Liverpool, and many other cities. The exhibit comprised a number of rail joints, electric-welded joints, portable cross-overs. The company also exhibited a Dupont truck having a wheel base of 5 ft. 6 ins., and a length over all of 13 ft. 4 ins.

THE ELECTRO MAGNETIC TRACTION COMPANY, LTD., showed a working model of a new system of electrical traction constructed under closed conduit surface contact system. The system is yet in its experimental stage, and no actual work has yet been done.

MOSSBERG ROLLER BEARINGS, LTD., had a neat little exhibit showing the application of roller bearings in various ways. They showed a pair of carriage wheels fitted with their patent roller bearings, one motor, car and wheel similarly fitted, and a tramway car axle box, and a various selection of small straight and end-thrust roller bearings.

W. F. DENNIS & COMPANY, sole agents in the United Kingdom for Felten & Guilleaume, of Germany, had a very attractive exhibit in which they showed the "Neptune" type of rail bonds in various lengths, both solid and flexible. They also showed trolley wire of the highest quality, in long lengths, weighing over 500 lbs., with specially soldered joints of a strength equal to the wires before drawing. Paper insulated cables for feeders, with single concentric, bi-concentric and stranded conductors for

low and high tension, were also shown in various forms, and guard wires, span wires, commutator bars and various covered wires, and bronze wires of all description were exhibited.

THE CHLORIDE ELECTRICAL STORAGE SYNDICATE, LTD., of Clifton Junction, Manchester, utilized its space to the very best advantage possible, by arranging in a very attractive manner numerous samples of storage batteries, as used for pressure regulation on numerous electric tramways and railways throughout the world. The various examples of different sized cells at present working in connection with electric tramway systems in Great Britain were easily identified by the printed cards attached to each. It was evident from the thoroughness of this exhibit that the storage battery is now forming an important part in central-station equipment, both for lighting and power work, affording an excellent means of allowing the steam engines to work during a large part of the time at their most economical load. The steam plant in stations which are thus equipped requires only to be sufficiently large to develop the average load, the storage battery supplying anything in excess and storing up any surplus. Samples were also exhibited of small batteries for the

VIEW OF THE WESTINGHOUSE EXHIBIT

automatic lighting of carriages on electric railways in the event of a breakdown at the power station, and batteries for self-contained cars, auto-cars, etc.

THE BRITISH INSULATED WIRE COMPANY, of Prescott, Lancashire, had a very tastefully decorated booth, in which were mounted samples of B. I. W. patent paper-insulated cables, as used for tramways in Aberdeen, Glasgow, Manchester and many other important cities. The company also showed a sample of a three-phase cable, as made for the Isle of Thanet tramways. This cable is being used as a three-phase feeder to the sub-transforming stations, with rotatory transformers transmitting power over 10 miles, the continuous low-tension current being supplied from the sub-stations through ordinary tramway feeders. The three conductors are separately insulated with impregnated paper, then stranded up together, and finally lead-sheathed under a hydraulic pressure of 3 tons to the square inch. This cable is made for a working pressure of 2500 volts, and is tested up to 10,000 volts. Samples of the company's well-known solid system, disconnecting joint boxes, etc., were also exhibited, while its standard section pillars in use at St. Helens, Blackpool and other towns were also shown, these having mounted on them switches of the duplex-knife type, four-line plug fuses with shield, lightning arresters, etc., etc. All these devices are carefully insulated from the slate with ebonite bushes, as is also the slate from the cast-iron pillar, and each pillar is equipped with a telephone set and board of trade terminals.

THE ELECTRIC TRAMWAYS EQUIPMENT COMPANY, of Birmingham, had erected a most practical exhibition of all its British-made overhead line material, and had a large sign over its stand with the words, "British-Made Overhead Line Material," which attracted considerable attention, as it is practically the only house in Great Britain which is manufacturing such material exclusively. In the company's booth, which was tastefully decorated, were shown samples of the company's insulators of the following types: Straight-line suspenders, single and double pull-offs, car-house suspenders, bridge suspenders, and bracket arm suspenders. A sample of the flexible bracket arm suspender was also exhibited, and a number of cap and cone insulators in straight line, single and double pull-offs, etc. A large assortment of the various forms of strain insulators was also shown, made of the "Verus" insulation, which the company claims is the first, and so far the only, insulation for trolley lines made in England. These comprise Globe strains, Brooklyn strains, Globe terminals, Globe turnbuckles, etc., and, in addition, a number of bronze ears for straight work and for curves, the latter being of a heavy section, and arranged for suspending by two insulators, this company being the first to introduce this principle. In addition the company had various samples of anchor ears, splicing ears, feeder ears, and a large number of section insulators, frogs and switches, car-house frogs with movable tongues, and all kinds of overhead crossings fixed and adjustable, and, in fact, every piece of apparatus necessary for the complete equipment of overhead-line construction.

MILLER & COMPANY, LTD., of the London Road Foundry, Edinburgh, had W. Gordon, one of its directors, in constant attendance, who succeeded most admirably in making a very attractive exhibit out of its car-wheel specialties. An exhibit of such material is hard to describe, as it only showed chilled car wheels and chilled iron points, but these were arranged in such a manner as to give an admirable appearance, and evidently attracted a great amount of attention from the electrical engineers and representatives of the various authorities and corporations who were present. The exhibit of chilled car wheels was interesting, as showing a sample of some wheels which have run over 100,000 miles with horse cars. With electric motor car wheels, in which it is now doing a large business, its wheels compete with any wheel which is made either in this country or America. It also showed a working model of a system of chilled iron double shifting points, as supplied to the Naples Electric Tramways, a system which has proved thoroughly efficient in service, and which has no spring to be clogged or get out of order. It also showed a wheel press, designed to work either by belt or hand—or fitted with both systems—up to 150 tons total pressure. Another design was also shown which is supplied for specially heavy work, capable of a total pressure of 250 tons. These are designed for pressing on or off the wheels on to shafts, and have been supplied to a great number of tramway companies in this country, on the Continent and in the colonies. The machines are of simple design, made of specially strong material, and every press is thoroughly tested before it is dispatched from the workshops.

THE J. G. BRILL COMPANY.—In addition to the Brill truck, which this company presented for view under a number of cars in the exhibition, the company had at the exposition its very latest and most complete type of convertible car—that is a car which can be made either a closed car or an open car at will. The windows and sides of the car, when open, are carried into the roof and can be lowered or raised at will. The company also showed samples of its 27-G pivotal truck, the 21-E truck, and a maximum traction truck. Most of these trucks are in extensive use in Paris and Great Britain, and are being widely adopted for the new work which is being done; also some handsome bronze models of these trucks which attracted a great deal of attention, and which, being mounted on tables, were readily accessible and could be examined carefully with ease. The company also exhibited a sample of its "Dedenda" gong, fitted on a stand ready for operation, and a number of brake handles were also shown in different patterns.

THE BRUSH ELECTRICAL ENGINEERING COMPANY contented itself with exhibiting one large car fully equipped. It was a bogie vestibule car, arranged to seat forty-four passengers in two compartments, divided into two classes if desired, or into smoking and non-smoking, the entrance being in the middle. The car was mounted on bogie maximum traction trucks, and its principal dimensions were: 39 ft. 6 ins. long, 6 ft. 10 ins. wide, and 4 ft. 8½ ins. gage. Each truck was equipped with a four-pole iron-clad motor, with ventilated armature and laminated pole

pieces, and was rated at 25 hp. The field coils are wound on brass spools, are of easy renewal, and the bottom half of the motor is made to hinge downward, either with or without the armature bearings. A series panel controller with emergency electrical brake and interlocking handles was also shown, and the company's regenerative tramway controller was attached, by means of which the weight of a car descending a gradient can be utilized to generate the current and return the energy to the line. The company also had on exhibition its type H. D. 2 of controller with electrical service brake, on which is a series parallel con-

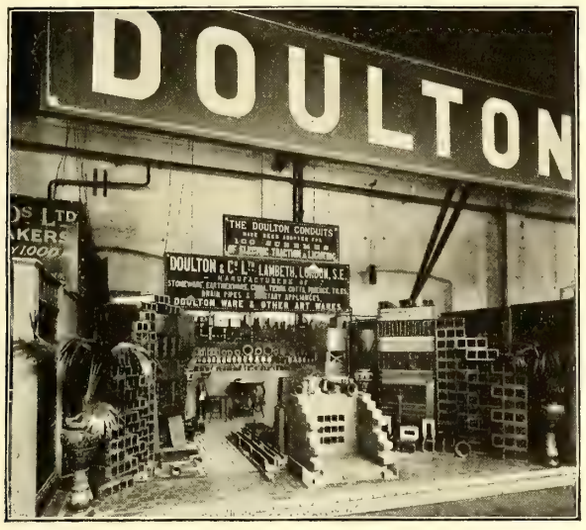


EXHIBIT OF DOULTON & CO.

troller with rheostatic brake, by means of which the speed of a car can be easily reduced, either gradually or suddenly, in case of emergency. The car, which was not equipped with top seats, attracted a lot of attention, and was favorably commented upon.

DOULTON & COMPANY, LTD., had an interesting exhibit tastefully arranged of its various manufactures in glazed stoneware conduits for electrical purposes. It also showed insulators and all kinds of stoneware and porcelain for electrical purposes, crucibles for electro-chemical manufacturing purposes, and a large assortment of tiles and faience now being extensively used in the walls and floors of power stations, where their cleanliness and durability render them particularly suitable. In addition, it exhibited also Doulton's patent water softeners and filters, which are now in successful operation in a large number of electric light and power stations.

CROSSLEY BROTHERS, LTD., had in operation two types of its well-known gas engines, viz.: Type S, giving 19 actual hp, and type O E, arranged for driving a dynamo for electric lighting without accumulators. Its latest type of oil engine, known as L L, was also shown, giving 2½ actual hp on a constant working load, and being equipped with all the latest improvements.

THE OHIO BRASS COMPANY, under the charge of A. G. Harwood, who has recently come across to represent the company in Europe, had a very handsome exhibit in the shape of a pyramid, displaying all the various insulators which it makes, such as trolley wire hangers and ears, strain insulators, section insulators, etc., etc. Surrounding the space was a brass railing, at the corners of which wood and iron poles were arranged, equipped with its well-known types of flexible pole brackets, one pole being equipped with a flexible bracket on which a suspension yoke was fitted for supporting two parallel trolley wires. The company also showed a great variety of section insulators, cross-overs of various styles and design for both round and figure 8 wire, and, in addition to the overhead material displayed, a variety of motor and car supplies, as well as a complete line of track bonding material, such as steel and copper bonding caps, channel pins and various styles of rail bonds. A number of adjustable track brush holders with steel wire track brooms and a Monarch track cleaner for the removal of snow, ice and dirt from tramway tracks also formed part of the company's exhibit.

MELDRUM BROTHERS, LTD., of Manchester, had an attractive space containing a sample of their well-known "Koker" mechanical stoker of the coking type, in combination with the well-known forced draft. They also exhibited the Meldrum "Simplex" destructor, as working in connection with the Darwen Electric Supply Station, where the town's refuse supplies all the power for the works. There was also shown a Beaman & Deas' destructor used for steam raising, and an econometer, an instrument for testing chimney gases, and thus readily discovering and remedying defective combustion.

ELLIOTT BROTHERS, of London, had an attractively fitted up booth in which they displayed a Board of Trade panel, with all the instruments for carrying out the tests required by the Board of Trade in connection with electric tramway undertakings. This board was complete with all the instruments mounted on it, and is similar to a number of such boards which have been built by Elliott Brothers to form part of traction switchboards. They also had a galvanometer and battery for testing the difference of potential existing between insulated returns and water pipes, and a number of Weston electrical measuring instruments of various designs and for various purposes. The exhibit also included a line of their various forms of recording wattmeter suitable for testing the current on motor cars, and showing in a graphic manner the amount of current taken at starting and when going on level, uphill or downhill. These instruments keep careful record of the fluctuations of the current, and are made also for recording volts. The paper speed in these instruments can also be regulated to be run out at 6 ins. per minute or 6 ins. per hour, and a large number of other useful instruments were shown, making a most handsome and interesting display.

HAROLD P. BROWN, of New York, exhibited the Edison-Brown plastic rail bonds, which seemed to attract a great deal of attention among the electrical engineers present. Mr. Brown himself attended to the exhibit, which, though really part of R. W. Blackwell's business, was of sufficient importance and interest to warrant a special space. He showed grooved rail joints and T-rail joints, all equipped with the plastic bonds, and a portable grinder and flexible shaft for applying rail bonds without drilling holes or weakening rails. He also showed a complete electrical testing apparatus for determining the conductivity of the rail bonds, rail joints, etc., the whole exhibit being most complete in every detail.

SMITH OF NEW YORK showed a complete line of headlights for electric and cable tramway carriages. Some of these were designed for the use of oil, though the majority were designed for electric lamps. He also had on exhibition incandescent clusters and combination center car lamps, many of these being of neat design and extremely useful, being adapted either for electric light or oil. He showed also a number of signal lamps and illuminating torches, self-contained and capable of giving a light equal

EXHIBIT OF THE ELECTRIC CONSTRUCTION CO.

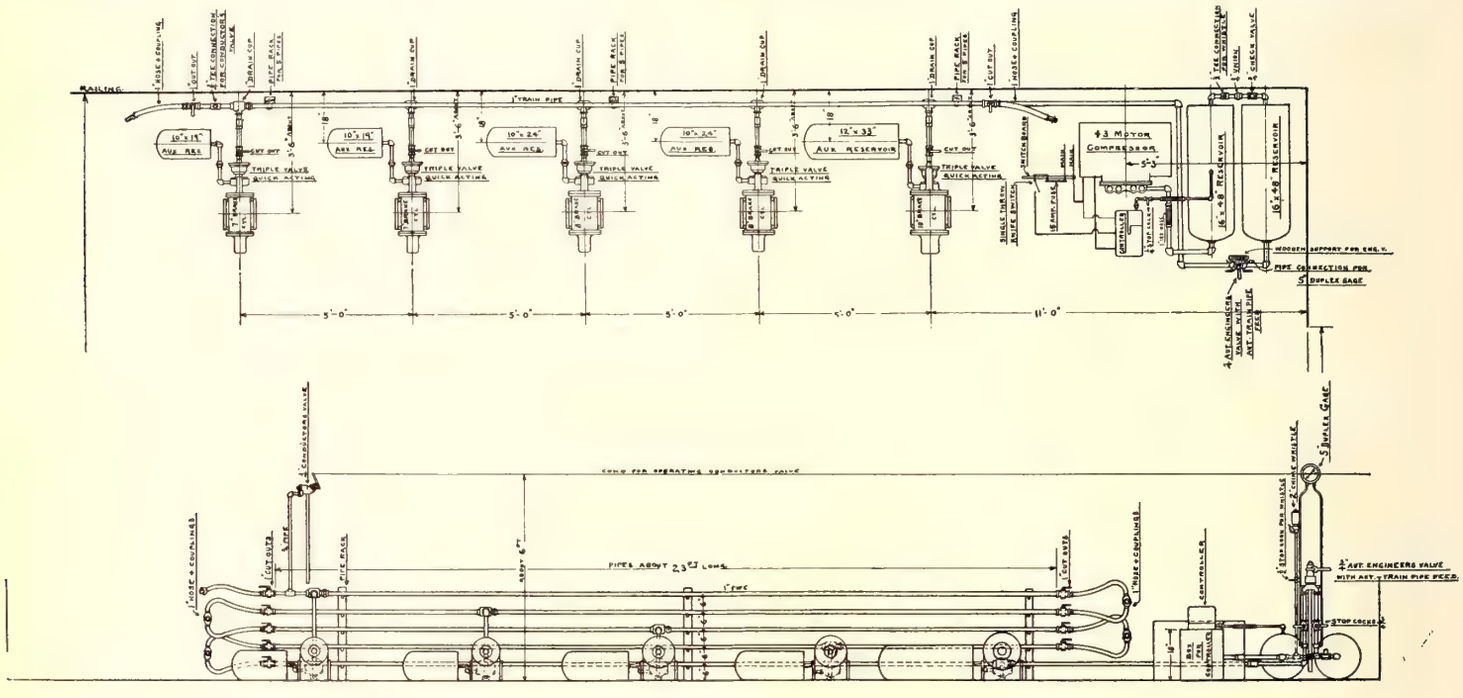
to 5000 cp, being specially interesting to railway and tramway engineers and contractors.

THE BRITISH GRIFFIN CHILLED IRON & STEEL COMPANY, LTD., had a handsome exhibit of chilled iron wheels, arranged in the shape of a pyramid, weighing 1 ton, and suspended from the center of a cast-iron test bar 12 ins. long by 1 in. square. In this company's space was also a pair of electric motor wheels which had been in service nineteen months and had run nearly 53,000 miles. One of these wheels was broken to show the fracture of the white hard iron of the chilled parts, changing very gradually into the tough gray iron of the body of the wheel. The company also showed standard motor wheels mounted on Griffin cold-compressed axles, center flange with double-tread wheel, American interurban type of wheels, Indian railway wheels

and a number of cold-finished axles in various stages of progress from the rolling mill to the finished axles.

THE BRITISH MANNESMANN TUBE COMPANY, LTD., showed a collection of standard poles as supplied by it for traction work. They are made from weldless steel tubing, and are supplied with scroll work or plain. They are made in one part or pieces, as required. The company also exhibited some samples of arc-lamp tests, as well as trolley poles, which are made of special steel with a very high elastic limit.

THE ELECTRIC CONSTRUCTION COMPANY, LTD., exhibited a 70-kw variable ratio transformer, now largely employed in the distribution of current on the Oxford system. Machines of similar construction are employed on the City & South London Railway, as reducers on the E. C. C. patented arrangement in which the high-tension pressure supplied is 1000 volts and the working conductors are 500 volts on the three-wire system. The arrangement of double field enables the ratio of the primary and secondary voltage to be varied within any desired limits, giving a high efficiency of conversion and compensation for line drop. The company also had on exhibition a tramcar motor of 30 hp, a good example of what British manufacturers can do in this line.



PLAN AND ELEVATION OF CHRISTENSEN EXHIBIT NO. 1

Stationary motors were also shown, capable of running continuously at a low temperature rise and of ability to withstand upward of 100 per cent overload for short periods. The company's exhibit also included an example of the company's trolley for side suspension, which is specially constructed for durability, lightness and the least possible risk of leaving the trolley wire or fouling the suspension brackets. Its regular switchboard apparatus was also exhibited, and the whole was supplemented by a fine series of photographs which conveyed an idea of the work which its shops are so well equipped for turning out.

THE ELECTRICAL POWER STORAGE COMPANY, LTD., showed various types of its well-known storage batteries and cells. First of all was the E. P. S. type, which is so thoroughly well known that it needs no description. Adjoining this were samples of the company's Faure King cells, specially adapted for traction work, and as used with the electric cabs in London and Paris. The company's "E" type is largely used for electric launches and also for train lighting in connection with Stone's system. The exhibit also included various types for stationary cells, which are largely used in Great Britain for railway and tramway generating stations. In addition the company showed a number of portable cells and batteries used chiefly for telephone, Roentgen ray, medical and dental work.

ASKHAM BROTHERS & WILSON, LTD., of Sheffield, had a most practical exhibition of its specialties for track construction, showing first of all a large show case containing assorted tool steel and also platelayers' tools of all kinds, such as picks, wedges, chisels, crowbars, hammers, etc. The company also showed some rail carts for the use of transportation of rails which are now a necessity with the long lengths and heavy sections which are now in use. It showed samples of its patent automatic spring points made of crucible cast steel, as supplied to Nottingham, Manchester and many other cities, as shown by a large map which it displayed. Adjoining these were movable points for junctions and cross-over roads, and crucible cast-steel crossings of various angles and sections. In another corner were also right-angle crossings, portable cross-overs for temporary track, while reconstructing, drain rails, drain boxes, springs, tires, wheels and axles and various types of joint plates and heel plates. Many samples of its special crucible steel castings for various purposes were also exhibited, as well as tiebars and fishbolts of wrought iron and mild steel. Another conspicuous feature was its patent points for cross-over roads on double lines of tramway, and, in fact, every possible piece of apparatus necessary for the complete equipment of track construction was included in the exhibit. Some very interesting protographs were also exhibited of special work which this firm has done in Sheffield, Leeds and other cities where complicated crossings have been constructed and work peculiarly difficult has been accomplished.

FRANK SUTER & COMPANY, LTD., sole agent in the United Kingdom for the Helios Electrical Construction Company, Ltd., has on exhibition some interesting samples of this well-known firm's construction. Firstly it exhibited a truck having a wheel base of 4 ft. 9 ins., the truck frame being supported on the axle boxes by means of spiral springs, and the car body being supported also on spiral and laminated springs on the frame, thus assuring quiet and easy running. Near these was also its car motor, the frame of which is cast in two pieces and arranged to open. Its controller was also exhibited, the contact cylinder of which rotates within a powerful magnetic field, which causes immediate extinction of all sparks. Its automatic maximum cut-out was also shown, and its overhead sliding contact gear which, owing to its great width, insures a reliable contact with the overhead wire. The reversing of the trolley rod is also saved, as by its elastic construction the gear changes its position automatically according to the direction in which the car is running. It also showed a complete line of overhead material with "Dirigo" insulation.

CHRISTENSEN ENGINEERING COMPANY, Milwaukee, had an exhibit of its own, although it was also represented by R. W. Blackwell & Co. It showed five different types of brakes. Exhibit No. 1 consisted of a motor-car equipment and train of four trailers with the Christensen quick-acting automatic air brake, with compressor type No. 3, provided with automatic controller, automatic engineer's valve and with automatic train pipe feed mechanism. Exhibit No. 2 represented a motor car and one trailer, with plain automatic air brake, motor compressor type AA1, with automatic governor and plain automatic engineer's valve. This exhibit was a duplicate of the equipment furnished the Cie. Générale de Traction, Paris, with the exception that the latter company is furnished with the axle-driven compressor in-

stead of the motor-driven. Exhibit No. 3 comprised one complete instruction stand representing the straight air-brake apparatus applied to a motor car. The compressor of this exhibit was also of type AA1. All the above exhibits were shown in complete operation. Exhibit No. 4 consisted of one portable air-compressor apparatus for furnishing compressed air for sand blast, air tools, air hoists, chippers, etc., etc. Exhibit No. 5 comprised various axle-compressor apparatus with governors, reservoirs and other air-brake apparatus, such as engineer's valve, triple valves, etc., which were arranged on tables for convenient inspection. Sectional parts of apparatus were also exhibited, showing the working of the parts clearly. The exhibit was in charge of the company's new European manager, W. A. Parker.

WITTING BROTHERS, LTD., of London, showed a very complete exhibit of the system as manufactured by the Electricité et Hydraulique Cie., of Belgium, and had at the exhibition standard trucks for light railways and tramways equipped with two standard tramway motors of 30 B. H. P., 500 volts, and 550 r. p. m. In this form of truck the end platforms are entirely independent of the car body. A Peckham truck was also shown equipped with similar motors. The exhibit also included a com-

VIEW OF ONE SIDE OF HALL

plete set of car fittings and electrical apparatus for handling cars, such as controllers, resistances, lightning arresters, canopy switches, etc., and various types of tramway motors of different horse-power and for operating at different voltages; also stationary motors of different sizes, both of the inclosed and semi-inclosed type, which are designed to operate at slow speed, having four poles with slotted drum armatures, with form-wound coils. The field-magnet coils are wound on bobbins, from which they are highly insulated by special waterproof and fireproof insulation; the complete coils are then slipped over the poles and kept in place by the extended pole shoes and by means of special bronze cheeks. It showed also various sizes of three-phase motors and single-phase Heyland motors, a 50-kw motor-generator, consisting of a 100-volt continuous current motor, driving a continuous current dynamo generating current at 500 volts. The two machines were rigidly coupled and mounted on the same bed-plate, and supplied power to various exhibits in the hall. It also exhibited a switchboard and various samples of cables manufactured by this company, and in addition it had an interesting collection of three-phase transformers of standard pattern, an electric percussion rock drill, automatic circuit breakers, arc lamps, switches and fuses, manufactured by the Electricité et Hydraulique Cie.

THE CONSOLIDATED CAR HEATING COMPANY, of Albany, showed an interesting collection of its various types of electric heating apparatus for tramway work, together with special switches and fuses, and special devices for work in connection therewith. The company drew particular attention to its temperature regulating switch, a device which allows the current to pass through either or both of the sets of the coils in its heater, thereby regulating the heat.

BERGTHEIL & YOUNG, of London, showed a complete line of trolley line insulators of the J. P. type, manufactured by the Johns-Pratt Company, of Hartford, Conn., the insulation being of molded mica. The company also showed samples of the Johns type of electrical heater, which provides a large radiating surface for the heat generated. It also had on exhibition a quantity of the "Noark" fuses of the inclosed type, capable of opening an electrical circuit at any of the various alternating or direct-service voltages in common use, without arc or flash, and at the same time of visibly indicating its condition.

WILKINS & COMPANY, of London, showed some interesting samples of wire ropes for various purposes. Chiefly interesting in this exhibit, however, were the ropes which it supplied for cable tramways.

HOLDEN & BROOKE, LTD., of Manchester, exhibited its specialties in steam separators, grease extraction, exhaust heads, steam injectors and other special steam and feed-water devices.

W. T. GLOVER & COMPANY, LTD., of Trafford Park, Manchester, exhibited a case of handsome samples of various kinds of its well-known cable, together with several large drums of lead-covered and steel-armored three-core cable for high-tension substation feeders, for polyphase systems, for either tramways or town lighting, and a large drum of single lead-covered cable for tramway feeders. It also showed a most interesting collection of joint boxes for single concentric, triple concentric, twin and three-core cable of all sizes, including patent closing connector to make T joint on to single cable without cutting the cable or using screw-fixed clamps. Various disconnecting, straight through and T boxes for single concentric and multi-core cables up to 1.5 sq. in. sectional area, with patent flexible links, were exhibited, together with other fittings used in cable connections. Samples also of patent solid ended flexible rail bonds with round and compressed strands were shown, and the whole exhibit was arranged in a most tasteful manner, some one of the company's engineers being in constant attendance.

FINALE

In addition to the exhibits already described, there were a number of other exhibitors of other machinery and machine tools and various appliances more or less applicable to tramway work, but which the space at our disposal prevents us from treating in detail. In the lesser hall were shown, also, a large number of novel seats designed for the tops of tramcars and omnibuses for the avowed purpose of keeping the seats dry in wet weather. It is impossible to describe them all, so that, perhaps, it will be sufficient to say that many were good, many were impracticable, but that nearly all had some points of merit. We have tried to give our readers a fairly accurate description of the chief exhibits, and if any of the exhibitors have been neglected, it is not from any desire on our part, but that they have been overlooked in the large number that were there. The exhibition, as a whole, was an immense success, reflecting the greatest credit on James W. Courtenay, the managing director, and A. M. Wilcox, the untiring secretary, and also on the exhibitors, who used the utmost diligence in getting their exhibits ready in time, and afterward keeping them in good order.

The World's Copper Output

The accompanying statement of the copper production of the world has recently been forwarded to the State Department by Vice-Consul Monaghan, at Chemnitz:

OUTPUT

Country	1898 Tons	1899 Tons	Increase P. Ct.	Decrease P. Ct.
Algeria	50	....	....	100.0
Argentine Republic	125	65	....	48.0
Australasia	18,000	20,750	15.3	....

The London Firm of J. G. White & Co.

Announcement is made in London of the organization of J. G. White & Company, Ltd., as electrical, mechanical and civil engineers and contractors, with a capital of £100,000, divided into 5000—6 per cent cumulative preference shares of £10 each, and 50,000 ordinary shares of £1 each.

The directors of the company are: Chairman, J. G. White, Ph.D., president, J. G. White & Company, New York; managing director, O. H. Baldwin, M. E.; A. N. Connett, C. E., chief engineer; E. B. Wyman, director Deep Leads Electric Transmission Company; W. C. Burton, E. E., electrical engineer. The secretary and treasurer of the company is A. H. Beatty.

This company has been formed to take over the foreign business (i. e., all the present business outside of North America) of J. G. White & Company, Inc., of New York, and to carry on a general electrical, mechanical, and civil engineering and contracting business throughout Great Britain, the Continent of Europe and other parts of the world, excepting North America. No manufacturing business will be done by the company, so that its business will not compete in any way with existing manufacturing companies. By carrying out an independent policy, it is believed that the confidence of financiers, manufacturers and engineers generally can be secured and a very large business developed.

The company will have an unusually competent and experienced staff, not only of electrical, but mechanical and civil engineers as well, as will be seen below.

The company's chairman, J. G. White, was graduated Bachelor of Arts at Pennsylvania State College, 1882, and after three years' post-graduate work, largely in electrical engineering, was graduated Doctor of Philosophy at Cornell University in 1885. After two years in charge of the Department of Physics in the University of Nebraska, Mr. White formed a company to do electrical engineering and contracting, and has since been the controlling spirit and active head of the business. This business has been conducted throughout the United States under his present management and control continuously for thirteen years. During that period a large and growing business has been developed. The work done has included the partial or complete equipment of many electric railways, among the number being those in the following cities and towns: Baltimore, Md. (about 200 miles); Buffalo and Niagara Falls, N. Y.; Washington, Charleston, Asheville, New Orleans, Nashville, Omaha, St. Joseph, St. Louis, Kansas City, Salt Lake City, Spokane, etc. The business has also included the designing and installation of a number of electric plants for lighting, and the installation of, or consulting engineering work for, a large number of electric power plants. Among the latter were the Niagara Power Company, complete designing and building of transmission line; subways for the Cataract Power & Conduit Company, Buffalo General Electric Company and city of Baltimore, and transmission plants in Helena and Cripple Creek. The work now being carried out by J. G. White & Company includes the following: Washington, D. C., equipment of about 60 miles of electric road; Toledo, Ohio, to Detroit, Mich. (54 miles), complete engineering and construction of electric railway; Perth, Western Australia, consulting engineering and furnishing plant for tramways; San Juan, Porto Rico, complete engineering and installation of tramways and lighting plant; Alton, Ill., consulting engineering Alton Railway, Gas & Electric Company; Winston-Salem, N. C., consulting engineering Fries Manufacturing & Power Company, rebuilding and extending railway, etc.; Colorado Springs, Col., consulting engineering, rebuilding and extending railway, electric light plant and large new electric power plant; Victoria, Australia, consulting engineering Deep Leads Electric Transmission Company (3000 hp); Kalgoorlie, Western Australia, consulting engineering Kalgoorlie Electric Power & Lighting Corporation; State of New York, consulting engineering and valuation of properties for State Board of Tax Commissioners; St. Louis, Mo., consulting engineering Imperial Electric Light, Heat & Power Company, extension of plant, etc. During the past five years the company has also done a constantly increasing business in the forming of underwriting syndicates to finance electrical properties, all of which have shown most gratifying results. The properties financed in whole or in part included the following: Buffalo & Niagara Falls Electric Railway Company; New York Electric Heat, Light & Power Company, New York City; Helena Water & Electric Power Company, Helena, Mont.; Colorado Electric Power Company, Canyon City, Col.; Alton Railway, Gas & Electric Company, Alton, Ill.

The company's managing director, O. H. Baldwin, received the two degrees of Mechanical Engineer and Electrical Engineer in 1885 from Stevens Institute of Technology, since when he has had the following experience: In the employ of the Pennsylvania Railroad Company, maintenance of way department and motive power departments until March, 1886. With the Westinghouse Electric & Manufacturing Company from March, 1886, until September, 1889, on general construction work and operation of electric lighting and power plants. In 1889 he was sent from Pittsburgh to London to serve as engineer to the Westinghouse Electric Company, Ltd., and also to superintend the running of the Sardina Street station of the Metropolitan Electric Supply Company, Ltd. While serving in this capacity, Mr. Baldwin drew up the plans for the boilers and piping work for the extension of this station, superintended its erection, and operated the extended plant for one year. In 1892 he was appointed chief engineer of the Westinghouse Electric Company, Ltd., London. In 1894 he was appointed managing director of the company. Some time since Mr. Baldwin was given the additional appointment of assistant manager to the British Westinghouse Electric & Manufacturing Company, Ltd., and has been acting manager of the business of this large company, no manager having been officially appointed. Since 1890 Mr. Baldwin has had general charge of all the engineering work of both the Westinghouse Electric Company, Ltd., and the British Westinghouse Electric & Manufacturing Company, Ltd.

J G. WHITE

A. N. CONNETT

A. N. Connett, chief engineer of J. G. White & Company, Ltd., was graduated in 1880 as civil engineer, at Rensselaer Polytechnic Institute, Troy, N. Y. From Jan. 25 to July 3, 1881, he was in charge of the survey at St. Charles, Mo., for the river improvement works of the United States Government. From July 4 to Sept. 7, 1881, he was resident engineer at Cowden, Ill., for the construction of the Toledo, Cincinnati & St. Louis Railroad. From Sept. 12 to Dec. 3, 1881, he was assistant engineer Union Pacific Railway, in charge of division of construction work on the Oregon Short Line in Idaho. From Feb. 20, 1882, to March 30, 1884, he was principal assistant engineer to William E. Northern (deceased), a very well-known engineer and a president of the American Society of Civil Engineers. From April 1, 1888, to Sept. 12, 1888, he was assistant engineer, with Knight & Bontecin, at Kansas City, Mo., on the plans of the Twelfth Street cable line at Kansas City. From Sept. 14, 1888, to May 10, 1889, he was assistant engineer with the Bentley-Knight Company on the construction of conduit electric tramways at Boston and New York. From May 14, 1889, to March 1, 1890, he was principal assistant engineer on the plans and construction of the Seventh Street cable line, Washington, D. C., for the Washington & Georgetown Railway Company, and from March 1, 1890, to March 25, 1891, principal assistant engineer with the Baltimore Traction Company on the construction of the Druid Hill Avenue cable line. From March 25, 1891, to July 10, 1891, he was divisional engineer, Broadway Cable Railway, New York, in charge of construction of division from Fourteenth Street to Thirty-seventh Street. From July 13, 1891, to Sept. 15, 1896, he was chief engineer, Baltimore City Passenger Railway Company; built and designed for the company 21 miles cable road, including three power houses and two car houses, also 20 miles electric railway with one power house and two car houses. The last year with this company Mr. Connett acted as general manager in addition to his duties as chief engineer. From Sept. 15, 1894, to Sept. 15, 1896, he acted as chief engineer, Metropolitan Street Railway Company, Washington, D. C., designed and built 21 miles conduit electric railway with two power houses and one car house. From Oct. 1, 1896, to the present time, he has been chief engineer of the Compagnie Francaise Thomson-Houston. While in Paris Mr. Connett has had charge of the numerous and large installations which have been made by his company. These have included the surface contact tramway

at Monte Carlo, which has operated quite successfully, and was the first commercially successful tramway of this type in the world. Among his other installations the tramways at Nice, described last month, are of particular interest. In the central portion of the city the tramways are operated by conduit, while in the more outlying and suburban districts the overhead trolley furnishes power to the cars. This entire system is operated from a station some 22 miles distant, which is driven by water power. One of his most noted installations is the tramway of Paris, described in December, 1899, and which is an unusual and improved type of conduit, and which is now operating very successfully. His work in France has included other tramway installations, most of which have been built on the overhead trolley system, and his work has also included electric light and power installations.

E. P. Jones, mechanical engineer of the company, has had twenty years practical experience in mechanical engineering work, a large part of it having been in connection with mining machinery of various kinds. He was for seven years with the Union Iron Works, of San Francisco, the largest builders of mining machinery west of Chicago. Of this time he was draftsman for three years, chief draftsman for two years, and assistant superintendent for two years. He was later mechanical engineer of the Anaconda Mines, in Montana, for one year, and still later, chief draftsman of the Risdon Iron Works, of San Francisco, for nearly three years, this firm being the second largest manufacturer of machinery in the United States west of Chicago. In addition to the above, Mr. Jones spent four years in general construction, erection and operation of mining machinery, and had also two years commercial experience in manufacturing and selling machinery. All of the above experience was in the United States, and after this Mr. Jones went to Western Australia to enter the employ of Bewick, Moreing & Company, having been selected to carry out important mechanical work for this firm by its San Francisco correspondents. Mr. Jones remained with this firm for some fifteen months, and then established himself very successfully as consulting mechanical engineer in Western Australia, from which place he has just returned.

A. H. Beatty, secretary of the company, entered the services of Monkhouse, Goddard & Company, chartered accountants, of London and Newcastle-on-Tyne, in the year 1885, as junior clerk, and remained in the services of that firm until 1892. During the above period Mr. Beatty rose from the position of junior to that of senior clerk, and in this capacity was intrusted with many investigations, comprising auditing accounts, and examining into the financial position of various firms and companies, both in England and abroad. Since leaving that firm Mr. Beatty has acted as accountant in a number of important transactions involving not only commercial management, but also practically the superintendence of the mining, engineering and electrical work.

The company has certainly started under the most favorable auspices, and should secure a large amount of work in its chosen field.

Car Body Specifications

The cars used on the Southwest Missouri Electric Railway are described and illustrated elsewhere in this issue. As they possess a number of interesting features the full specifications are given herewith:

DIMENSIONS

	Feet	Inches
Length of car body over corner posts	30	6
Length of car over vestibules	40	2
Length of car over bumpers	41	2
Width of car body at sill, over plates	8	3½
Width of car body at belt rails	8	3½
Width of car body over water drip rails	8	4½
Height of car body from underside of sills to top of roof, not including trolley board	9	0
Height inside, from floor to top plate	6	3
Height inside, from top of floor to underside of upper deck ceiling	8	2
Height from track to underside of sills when car body is mounted on trucks	3	1

BOTTOM FRAMING

Side sills of very best quality long leaf yellow pine, size 4½ ins. x 7¾ ins. finished, re-enforced on the outer sides with steel plates; plates to be ⅝ in. thick, 7 ins. wide, extending full length of car body and around corners to door posts on ends in one continuous piece, and securely bolted to sills with oval head carriage bolts.

End sills of oak, size 7¾ ins. x 4⅞ ins. finished.

Cross sills of oak, size 6⅞ ins. x 2¾ ins. finished.

Diagonal braces of oak, size 4 ins. x 1¼ ins. finished.

Trapdoor framing to be arranged to meet the requirements of the ———— motor, for ———— two motors to each car, of type No. ———— and of ———— hp each.

Bottom framing to be also arranged to meet the requirements of the ———— double trucks, with wheels 33 ins. in diameter; wheel base of trucks ———— distance between centers of truck bearings ————; bolsters to be set back ———— from end of car body.

Gage of track 4 ft. 8½ ins.:

Bottom framing to be tied together with ⅝ in. round refined iron rods, one for each through cross sill, extending across the whole width of bottom frame and through side sills and plates, with thread and nut at each end.

Short framing and trapdoor framing to be also tied together with ⅝-in. round refined iron rods and plated where necessary.

Body bolsters to be made of 9 ins. x ⅞ in. and 9 ins. x ⅝ in. iron filled with oak, made to suit the requirements of the trucks and securely bolted to car body.

Truss Rods: Inside trusses to be made of 2 ins. x ½ in. refined iron, with 1-in. round ends with thread and nut. These trusses to be placed as high as possible and out into posts, and securely fastened to posts and sills.

Also truss rods of 1-in. round iron to be placed underneath side sills to support center of car, with turnbuckle in the center, and securely bolted to sills at ends.

Floor to be of best quality quarter-sawed yellow pine, ⅞ in. thick with 2⅛-in. face, tongued and grooved, closely laid longitudinally with car and securely nailed to bottom framing. Floor to be of two thicknesses, the lower layers being laid crosswise and the top floor to be laid longitudinally with car.

Trapdoors to be fitted with large wrought-iron handles, countersunk into trapdoors and bolted through.

All parts of bottom framing and under side of floor to be painted with brown oxide of iron paint, and all mortises and tenons to be thoroughly white-leaded when being put together.

BODY FRAMING

All posts, rails and other parts of body framing to be of best quality tough ash. Ventilator rails to be faced with oak on the inside and moulded.

Side of car to be framed for eleven windows on each side with straight siding below windows.

Ends of car to be framed for double doors, and one window at each side of door opening.

Posts to be well braced diagonal cross bracing between posts, made of oak ⅞ in. x 3½ ins. and tightly fitted. Outside of car below window to be sheathed with matched poplar sheathing vertically and well nailed to body framing, sheathing to be ¾ in. thick and 2 ins. wide on face.

Inner side of sheathing to be backed with best quality linen scrim well glued to sheathing, posts and bracing, and when the glue has become hardened the scrim to be painted with brown oxide of iron paint.

The joint between sill plate and sheathing to be covered with 1¼-in. x ¼-in. half oval moulding extending full length of body at sides, also on ends.

The joint between arm and rail and top edge of sheathing to be covered with 1¼-in. x ¼-in. half oval iron moulding extending full length of body and around corners to door posts on ends in one continuous piece.

Posts to be secured at bottom with strap bolts made of 1¼-in. x 5-16 in. iron, extending through sill with thread and nut at bottom. Strap bolts to have heel bent over on top and cut carefully into posts, and to be securely screwed to posts.

Posts to be tenoned, and sills and top plates to be mortised, drawbored and pinned, and all pinning to be done in such a manner that pins will draw tenons into mortises.

Top of posts to be provided with wrought-iron T-plates securely fastened to posts and top rails.

Side top rails to be of best quality yellow pine, size 4¾ ins. x 3 ins. finished, strengthened by a heavy letter panel made of ash 1⅛ ins. thick and 7 ins. wide, which is gained into top rail as well as posts.

Under drip rail to be 2¼ ins. x 2¼ ins. x ¼ in. angle iron, extending from corner post to corner post in one continuous piece and securely screwed to posts and letter panel.

Arm rail of ash, size 1¾ ins. x 4⅛ ins. finished.

Side posts of ash, 2¼ ins. thick, cut to pattern.

Corner posts of ash, 4 ins. thick, cut to pattern.

Diagonal bracing between posts of oak, size ⅞ in. x 3½ ins.

Truss plank at bottom, inside, of ash, size 1¼ ins. x 9 ins.

Door posts of ash, size 2½ ins. x 2¼ ins. Each door post shall be provided with one ⅜-in. round iron rod, extending from top of headpiece through to bottom of end sill, screwed to headpiece and let into door posts, and to have thread and nut at bottom.

ROOF

To be of the monitor-deck pattern full length of car. All parts of roof framing to be of best quality tough ash. Ventilator rails to be faced with oak inside and molded.

Lower ventilator rail of ash faced with oak, 2½ ins. x 4½ ins.

Upper ventilator rail of ash, size 2¼ ins. x 3¼ ins.

Ventilator munions of ash or oak, size 1⅜ ins. x 2¼ ins.

Side of lower deck carlines of ash, size 1⅛ ins. x 2 ins., cut to pattern, glued and tenoned into lower ventilator rail, and shouldered, glued and screwed to side top rail.

Center of upper deck carlines of ash, 1⅛ ins. x 1¾ ins., cut to pattern, glued and screwed to top ventilator rails.

Roof to be further supported by ten steel carlines, one over each intermediate side post, made of 1¼-in. x ⅜-in. steel, forged to shape of roof in one continuous piece and extending from side top rail to side top rail, with a foot at each end, which is securely screwed to side top rails. Steel carlines to be securely bolted to wood carlines.

Roof framing to be covered with matched poplar sheathing ½ in. thick and 3 ins. wide, closely laid and securely nailed to roof framing.

Outside of roof sheathing to be painted with brown oxide of iron paint, and then covered with No. 8 cotton duck, and outside of duck covering to be painted three coats of lead and oil paint before trolley board is placed in position.

Inner side of roof sheathing to be painted with brown oxide of iron paint.

The entire upper deck of roof to be covered with roof mats made of ash slats, placed on ash cleats laid in white lead, and securely screwed to roof framing.

TROLLEY BOARD

To be of best quality of white pine, made of two boards 1¾ ins. thick, 6 ins. wide and 11 ft. long, placed 4 ins. apart on center of roof, placed on ash cleats laid in white lead and securely screwed to roof.

All parts of trolley board and roof mats to be well painted with lead and oil paint.

Bolts to be provided for securing trolley pole base of stand, and to be located to suit the ———— base.

Roof mats to be placed on lower decks at diagonally opposite corners of car, also black steps on corner posts and grab handles on roof at same corners, of black.

PLATFORMS AND VESTIBULES

Platform outside knees of oak, 3½ ins. thick, 8 ins. wide.

Platform inside knees of oak, 3¾ ins. thick, 8 ins. wide.

Platform inside knees of oak, 2¾ ins. thick, 8 ins. wide.

All platform knees to be re-enforced with 5-in. x ⅝-in. iron plates extending full length of knees and securely bolted to same. Platform floor to be of best quality quarter-sawed yellow pine ⅞ in. thick with 2½-in. face, laid crosswise and securely nailed to platform framing.

Distance from top of car floor to top of platform floor 6⅞ ins. Platforms to be 4 ft. 10 ins. long from end of car body to outside of vestibule front at center of car, enclosed at front by stationary vestibule, with folding doors at both sides hung to vestibule corner posts, also folding gates for summer use. Vestibule to have three sash at front, the sash in center opening to drop, and all other sash to be stationary.

All framing parts of vestibules to be of best quality tough ash. Lower part of vestibule fronts to be sheathed with matched poplar sheathing, placed vertically same as on sides of cars, sheathing to be ⅝ in. thick and 2 ins. wide on face, and securely nailed to vestibule framing. Inner side of sheathing to be backed with linen scrim and painted same as on sides of car.

Inner side of vestibules to be finished in oak throughout, finish at bottom to be panel work, all finished in the natural color of the wood and varnish.

HOODS

To be of the street-car pattern. The bow to be of oak 1⅛ ins. x 1⅝ ins. steamed and bent to shape. The carlines to be of ash ⅞ in. x 1¼ ins. steamed and bent to shape, shouldered, glued and securely screwed to bow. Hood carlines against end of car to be of ash, 1¼ ins. x 1½ ins.

Hoods to be covered with matched poplar sheathing ⅜ in. thick and 2½ ins. wide, bent to shape and securely nailed to bow and carlines.

Outside of sheathing to be painted and covered with cotton duck, and outside of duck covering to be painted three coats of lead and oil paints.

Inner side of hoods to be painted same color as outside of car body.

Outer edge of hoods to be provided with an iron guard to prevent trolley pole from wearing out canvas covering.

SMOKING COMPARTMENT

Each car to have a smoking compartment at one end, 7 ft. 8¼ ins. long between end linings, with longitudinal side seats made of oak and varnished.

Partition between smoking compartment and balance of car to have a single sliding door, 25-in. opening.

Windows at each side of door opening in partition to be glazed with clear glass; also glass in door to be clear.

WINDOWS

Eleven on each side of car, and two at each end. Each window opening to have two sash, the upper one to be stationary and the lower one to drop flush with arm rail. All window openings at sides of car to be provided with a hinged casing covering space between sash and inside lining, which will close the opening both when sash are up and down. The lower outside end sash to be made to drop, and the inside end sash to be hinged and fitted with brass wire cloth.

INTERIOR FINISH

Interior finish of car body and vestibules to be of quartered oak throughout, of modern design and secured in place with solid black overhead screws.

End and side linings of oak, ¾ in. thick, with raised panels 9-16 in. thick.

Doors—
- Center rails of oak, 6½ ins. x 1 5-16 ins.
- Lower rails of oak, 8¼ ins. x 1 5-16 ins.
- Upper rails of oak, 4½ ins. x 1 5-16 ins.
- Side door stiles of oak, 4½ ins. x 1 5-16 ins.
- Center door stiles of oak, 4 ins. x 1 5-16 ins.
- Panel mutins of oak, 2 ins. x 1 5-16 ins.
- Raised panels of oak, 7-16 ins. thick both sides.

Sash—
- Bottom rail of oak, 3½ ins. x ¾ in.
- Top rail of oak, 3⅞ ins. x ¾ in.
- Side stile of oak, 2 1-16 ins. x ¾ in.

Deck sash—
- Lower rail of oak, 1½ ins. x ¾ in.
- Upper rail of oak, 1 3-16 ins. x ¾ in.
- Side stiles of oak, 1 5-16 ins. x ¾ in.

Transom sash in ends—
- Lower rail of oak, cut to pattern, 1¼ ins. x ¾ in.
- Upper rail of oak, 1 in. x ¾ in.
- Side stiles of oak, 1⅛ in. x ¾ in.

CEILING

Of three-ply birch veneer, plainly decorated and varnished. ceiling and ceiling moldings to be secured in place with screws, and ceiling moldings to be grooved on back to receive the lamp wires. Back of ceiling to be painted with brown oxide of iron paint.

DOORS

Automatic double doors at each end of car, made of oak with oak panels, hung at top with contra-twist door fixtures. Door in partition to be hung with hangers and track. Door openings at ends of car to be 40 ins. wide and 6 ft. 3 ins. high, and door opening in partition to be 25 ins. wide and 6 ft. 3 ins. high. All doors to have stationary glass.

SASH

All sash to be ¾ in. thick and made of oak.

DECK SASH

Eleven on each side of car, pivoted and made of oak. The ends of ventilator or monitor deck to be divided into three spaces, with pivoted sash in center opening and stationary glass in side openings.

GLASS

The glass in all windows and doors to be first quality double thick American window glass, imbedded in molded rubber on all edges to prevent rattling. Glass in deck sash to be double thick white chipped, with 1 in. clear edge and imitation bevel.

CURTAINS

All side and end windows, also outside of end door openings to be provided with curtains. Curtains to be made of Pantasote material, pattern "H" color 74, mounted on Hartshorn 1-in. spring rollers and fitted with the Burrowes No. 83 fixture at the bottom.

Curtains on outside of end doors to be made up in same manner as the other curtains, to be placed in a neat oak box over door opening with side pieces extending down to arm rail to form guides for curtain fixtures.

SEATS

There are to be eight (8) on each side of car in large compartment, six of which are to be of Hale & Kilburn's No. 80½ Walk-over pattern, and four stationary seats; the two stationary seats at end next to vestibule to be placed longitudinal with car, and the two stationary seats next to partition to be placed crosswise.

Cushions of all reversible and the two longitudinal stationary seats to be 33 ins. long and the two stationary seats next to partition to be 31 ins. long. Backs of all cross seats to be 22 ins. high, and those of the longitudinal seats to be of same height as side lining (13 ins.). All reversible cross seats to have grab handles on corner of back at aisle end, also movable foot rest and thumb latch on seat back levers. All seat cushions to be 18 ins. wide. All seat and back cushions to be covered with canvas-lined rattan with hard enamel finish. Space between center of stationary cross seat and the first reversible seat to be 37 ins. Reversible seats to be spaced 17 ins. between edges of seat cushions when passengers are facing each other, and 16½ ins. between edges of seat cushions when backs are all turned same way.

Aisle through center of car to be 20 ins. wide.

HAND RAILS

To be placed in smoking compartment only, supported by black ornamental brackets. Rails to be made of oak 1⅛ ins. diameter, with polished black ends. Each rail to be supplied with six (6) padded hand straps made of fancy leather and fitted with black buckle.

FLOOR MATS

Everett pattern, made of ash slats ⅝ in. thick, ¾ in. wide, placed ¾ in. apart, extending longitudinally in aisle full length of car and sunk flush with the floor.

TRIMMINGS

Of very best quality black metal, dead finish and secured in place with solid black screws.

GRAB HANDLES

Long vertical grab handles to be placed on posts at each side of each vestibule entrance, made of 1-in. steel-lined black tubing fitted into black end sockets, 36 ins. long, and securely screwed to posts with solid black oval head screws.

WINDOW GUARDS

Three bar window guards to be placed on outside of all end windows, made of ½-in. heavy black tubing filled with hardwood and secured in place with solid black screws.

SIGNAL BELLS

Two 6-in. steel conductor's signal bells to be supplied with each car, with necessary cords of 5-16-in. round oak tan leather extending through center of car suspended from ceiling with suitable black hangers with 13-in. drop.

REGISTER

One Meaker fare register of latest pattern to be furnished with each car, with necessary cords of 5-16-in. round oak-tan leather extending along ventilator rail at each side full length of car and onto both platforms, suspended by suitable brackets or guides.

WIRING

Car bodies to be wired for light and trolley circuits. Light circuits to be arranged for four single lights on each ventilator rail in large compartment, and two single lights in upper deck of smoking compartment.

All wiring material, sockets and switches to be furnished by the railway company.

HEADLIGHT

Each car to be equipped with one Wagenhals' electric arc headlight complete, arranged to hang on front of vestibule.

HEATERS

Each car to be equipped with sixteen electric heaters, type to be selected by the railway company.

SAND BOXES

Each car to be equipped with two (2) sand boxes—one at each end at diagonally opposite corners of car, placed under seats, arranged to operate by foot lever, and supplied with removable hose.

GONGS

Two 14-in. steel foot alarm gongs to be supplied with each car, one under each platform.

BRAKE STAFFS

One on each platform, 1¾ ins. round at the bottom, forged tapering to 1 in. round at the top, well braced, fitted with 12½-in. black ratchet brake handle and ⅜-in. twist-link Norway iron brake chain.

PLAFORM STEPS

Double steps at each platform entrance, sides of steps to be made of steel plate ¼ in. thick, with treads of ash ⅞ in. thick and 8½ ins. wide. Distance between end of car body and inside of platform crownpiece 38 ins. Distance from outside of car side to outside of platform knee 13 ins. Distance from top of platform to first step 11 ins., and from top of upper step to top of lower step 10½ ins. Distance from top of platform floor to underside of bottom step 24 ins. Distance from top of platform floor to top of car floor 6⅞ ins. Edge of bottom step to project 1½ ins. beyond side of car. Outer edge of step treads to be covered with iron molding.

DRAW-BARS

Extra heavy radiating spring draw-bar at each end of car, with necessary slides, all securely bolted to car body. Height from track to center of draw-bars when car body is mounted on trucks to be 22½ ins.

BUMPERS

Angle iron bumpers to be placed on front of vestibules, made of 6 ins. x 3½ ins. x ⅜ in. angle iron bent to same shape as vestibule front, and extending full width of same, projecting 6 ins. beyond front of vestibule and securely bolted to platform knees, which project out for that purpose. Height from track to center of bumpers to be 33½ ins.

MATERIAL AND WORKMANSHIP

All material entering into the construction and finish of these car bodies to be of the very best quality; all sills to be full length without splicing; mortises and tenons to fit each other tightly without false filling, and to be thoroughly white-leaded when being put together; all lumber to be of the very best quality and thoroughly well seasoned and dried; and all work to be done on a strictly first-class workmanlike manner.

CORNER POSTS AND HEADPIECE

To be securely tied together with an angle iron brace let into top of headpiece, corner post and side top plates. Outside of corner post, where it joins plate and headpiece, to be protected by a heavy iron plate.

Corner iron to be placed in corners of hoods where the bow joins the rear carline.

PAINTING

These car bodies to be painted in the best possible manner, lettered, ornamented and striped as desired by the railway company, and varnished throughout with Nobles & Hoare's railway varnish.

Outside of car to be painted in the following manner:

Two coats of pure white lead and linseed oil.

After second coat cars to be puttied and plastered where necessary.

Car to be rubbed with pumice stone and water until a perfectly smooth surface is obtained.

Two coats of flat body color, and if necessary an additional coat will be put on, depending on color used.

One coat color and varnish, on which striping and lettering will be done.

Two coats Nobles & Hoare's rubbing varnish, second coat to be rubbed with pulverized pumice stone and water.

Two coats Nobles & Hoare's railway body varnish. All striping to be done in gold. Lettering and numbering to be of same size and style as shown by photograph to be sent by railway company.

Roof of cars to be painted three coats of lead and oil paint, each coat to be allowed to dry before the succeeding coat is applied.

Inside work to be finished in the following manner:

All parts of inside woodwork of car and vestibule to receive one coat of oil filler, one coat of pure linseed oil, and three coats of Nobles & Hoare's rubbing varnish, last coat of varnish to be rubbed to a cabinet finish. No shellac to be used on any part of the cars.

INSPECTION

The railway company shall have the privilege of sending a representative to the shops of the car builders to inspect and examine the cars while being built.

TRUCKS, MOUNTING MOTORS AND INSTALLING ELECTRICAL EQUIPMENT

The Southwest Missouri Electric Railway Company to furnish and deliver free of any expense at the works of the car builders all necessary trucks, motors, wire, switches, sockets and all other electrical equipment for these cars, and the car builders to install same without any extra charge.

TIME OF DELIVERY

These car bodies to be delivered complete, f. o. b. cars Webb City, Mo., on or before ————, 1900, subject to delays caused by fire, labor trouble or any other cause beyond the control of the car builders.

The Adrian (Mich.) Street Railway is to be completely overhauled and reconstructed. A. P. Southworth, owner of the property, has succeeded in floating a bond issue of $25,000, and the company has received a new and favorable franchise from the city.

The Worcester Consolidated Street Railway Company has about completed the extension of its Market Street car house. The new addition will accommodate about sixty cars.

The J. G. Brill Company's Exhibit at the Paris Exposition

The J. G. Brill Company, of Philadelphia, has an exhibit of cars and trucks at Vincennes, and an exhibit of models and photographs in the American section of the Transportation Building on the Champ de Mars.

In the Transportation Building at Vincennes this company shows four types of trucks, a type of convertible summer and winter car, and a standard sweeper for meter-gage roads. One of the trucks is a No. 21-E truck of the company's standard pattern, mounted on 33-in. wheels, and having a 6-ft. wheel base and 3½-in. journals. The spring base of the truck is 14 ft. 6 ins. A No. 27 truck of standard type is also shown. It has 33-in. steel-tired wheels, and was built for standard gage, and for a car body having a weight of about 22,500 lbs. The truck itself weighs 9450 lbs., and is fitted with G. E. 55 motors. This is the type of truck specially recommended by the Brill Company for the very heaviest service.

There is also shown a No. 27-G truck, with a 4-ft. wheel base, and built for a gage of 4 ft. 8½ ins. The width in this case was restricted, so that it measured no more than 2 m at any point. The truck has 30-in. wheels, and is intended for a car body of sufficient size to carry eighty passengers.

A maximum traction, or No. 22 truck, fitted with 30-in. and 22-in. wheels, completes the exhibit of trucks at Vincennes. This maximum traction truck has a 4-in. wheel base, and is equipped with G. E. 52 motors. It is built for standard-gage tracks. The special feature of this truck, which attracts considerable attention from engineers, is the side pieces of the frame, which are solid forgings. These forgings, although an extremely difficult and intricate piece of work, have come out with perfect success, and are specimens of a high grade of workmanship. A number of these forgings are also shown unassembled. The maximum traction truck is also intended for a car body accommodating eighty passengers.

The greatest novelty of the Brill exhibit, to foreign managers, is a convertible car of standard type, mounted on a No. 21-E truck, with 33-in. wheels. The truck has a 7-in. wheel base, but is intended for meter gage. The spring base is 15 ft. 6 ins. The car has metal panels, both sash and panels sliding into the roof and making the car, when they are up, as completely open as the standard pattern.

The Brill Company also exhibits one of its standard sweepers for meter-gage roads. This sweeper, which was illustrated last month, has a 6-ft. wheel base, and is mounted on 33-in. wheels. The sweeper is arranged with two brooms and a scraper, to clean the track in front of the trail broom. It also has the usual wings for increasing the width of the space cleared. Aprons are dropped over the brooms to prevent the snow from being thrown on the sidewalk. Two motors are provided for propulsion, and one for driving the brooms. All the machinery, and what would ordinarily be the platforms, are inclosed so as to protect the men.

A swinging easel contains photographs of Brill cars and trucks in use in the United States, England, France and Germany, and a framed photograph gives a view of the company's works.

The Brill exhibit at the Champ de Mars is located in the American section of the Transportation Building, on the first main aisle when entering from the Avenue Suffren. The exhibit consists of four truck models in bronze, a swinging easel with photographs of the company's types of trucks and cars, and a photograph of the works. The four models, which are made to scale, comprise a No. 27 truck, a No. 27-G truck, a No. 21-E truck and a pair of maximum traction trucks, with frame mounted upon them, representing the floor frame of a car, and illustrating the working features of the trucks.

The photographs illustrate nearly every type of car used in America, and are of such size as to clearly show the peculiarities of American construction. There are shown, also, views of Brill cars and trucks in use in many foreign cities, which would indicate that the Brill Company does business in nearly all of the countries which have reached the state of civilization marked by the use of trolley cars. It will, therefore, not be a surprise when it is stated that in a number of the foreign sections in the Transportation Buildings at Vincennes and at the Champ de Mars are shown cars mounted on Brill trucks. In the city of Paris, Brill work is especially in evidence. In going to the Annex of the Exposition at Vincennes, for instance, one rides on Brill trucks, whether starting from the Bastille or from the boat landing at the Pont National, and when passing the Madeleine Church on one of the large double truck cars, one is carried on trucks from the same shops. It would lead too far, however, to mention all of the tram lines in Paris on which Brill trucks are used.

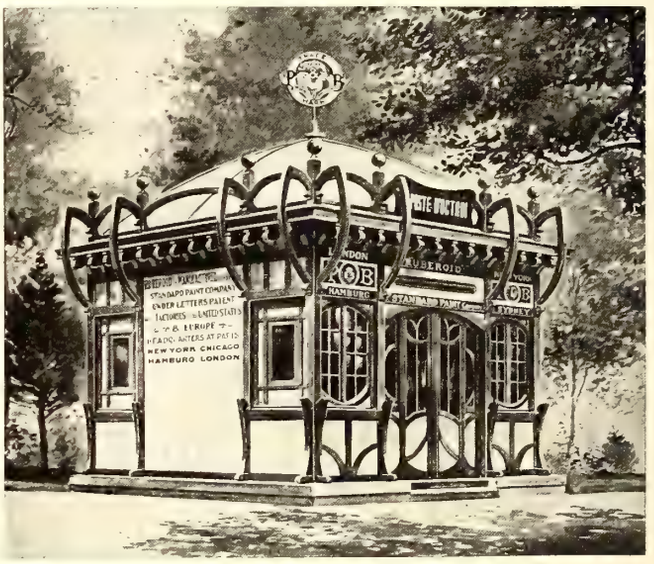
In a pamphlet prepared for the jury of the Exposition, it is stated that the Brill Works were founded in 1859, and that the beginning was on a very small scale, not more than four or five workmen having been employed, while the present number is 1400. The company manufactures annually 2000 electric cars and 9000 trucks, and the export business in 1899 exceeded f.5,200,000.

In England and on the Continent the Brill Company is represented by Maskell E. Curwen, whose headquarters are at 17 Victoria Street, Westminster, London, S. W. Mr. Mueller, the Exposition representative, has his headquarters at Vincennes.

The "P. & B." Paris Exhibit

Among the most novel of the American exhibits at the Paris Exposition is a pavilion erected by the Standard Paint Company, of New York. It is unique in construction and in its location at the Avenue d'Jena entrance. The inscription "Standard Paint Company," the American and European trade-marks and the various head offices—New York, London, Paris, Hamburg, Berlin and Sydney—appear on the front of the pavilion, while, surmounting the roof as a weather-vane, is the well-known "P. & B.," with the rooster trade-mark in gold. The trade-mark seems peculiarly fitting in a place so entirely Gallic in character, as the building itself is occupied by the officers of the Paris customs, which is indicated by the legend "Poste d'Octroi."

By special concession, after the French architects had themselves made successful use of P. & B. Ruberoid in the hallways and on the stairways of the chief operating building of the Expo-



P. & B. PAVILION AT PARIS

sition commissioners at No. 2 Avenue Rapp for more than a year before the Exposition opened, it was arranged that an ornamental pavilion, to be constructed inside and out, flooring, sides, ceiling and roof, of Ruberoid, should be erected for the use of French authorities in the Colonial section. Thus, a building purely American in material is being actually used during the term of the Exposition by the French Government. It is classified in the section of Architecture.

The Ruberoid covering the exterior is decorated in imitation of gray birch, with pilasters in oak. The roof is Ruberoid undecorated. The interior walls, above the base of imitation wood, are tastefully painted in floral designs on a delicate background, as in fresco. The ceiling is panelled and the Ruberoid elaborately decorated in allegorical design, emblematic of the American, European, Asiatic and African continents. The flooring bears a tastefully colored border in Grecian design. Though Ruberoid was in service as a decorated flooring at the recent Brussels, Sydney and other expositions, the Paris decorations are of a higher artistic grade than has heretofore been attempted. The roofs of the exposition warehouses in the Rue Javelle are also covered with Ruberoid.

In the American section (Machinery and Electricity Department) the P. & B. electrical compounds, insulating varnish and tape are shown; in the Civil Engineering and Transportation Department are the well-known P. & B. insulating papers, roofing and other products of the Standard Paint Company.

The Neal-Jupiter Brake

James H. Neal, who is connected with the Boston Elevated Railway Company, and has already made several inventions, including the Neal electric headlight, has recently brought out another invention, which is claimed to answer all the requirements of an efficient and reliable brake. The United States Steel Company, of Boston and Everett, Mass., has acquired the right of manufacture, and is now making one of these Neal-Jupiter brakes—so called after the inventor and after the brand of steel manufactured by this company. A car of the Boston Elevated Railway Company will be fitted up and in running order before the middle of August.

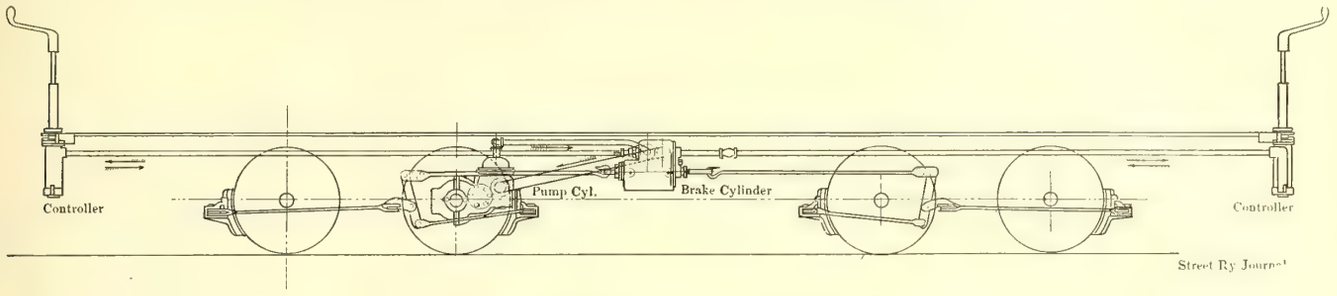


DIAGRAM SHOWING ARRANGEMENT OF BRAKE

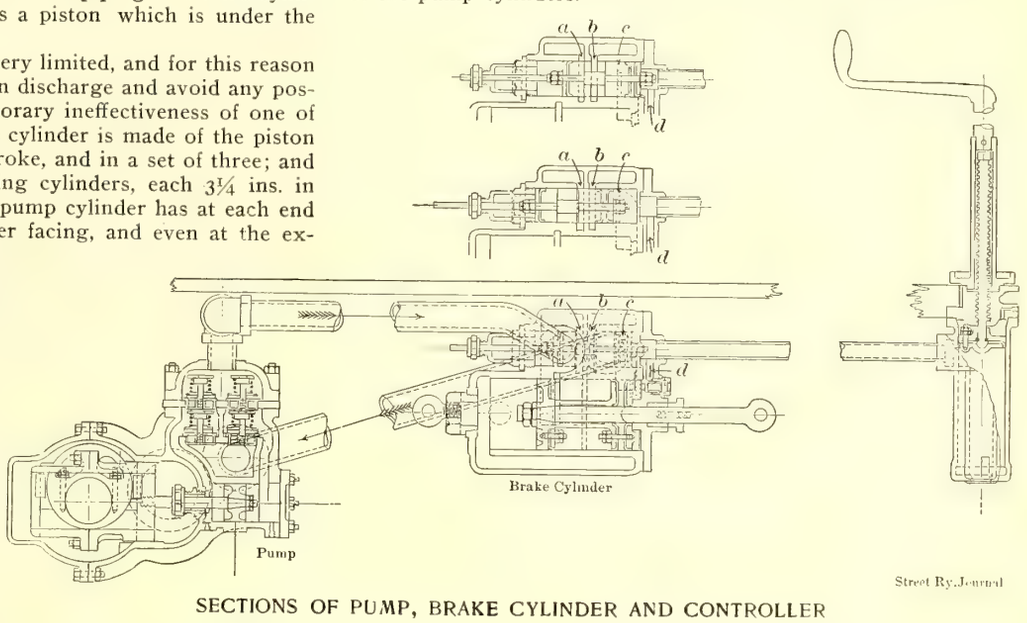
Before mentioning the advantages claimed for this new brake, it will be well to refer to the drawings here given, and to give a description of it first.

The device consists essentially of a pump, or set of pumps, placed underneath the car platform, and operated continually by one of the car axles, to which they are attached. These pumps discharge into another cylinder, which actuates the brakes. The latter, called the brake cylinder, is connected by flexible piping to a third cylinder called the controller which has a piston which is under the direct control of the motorman.

The space underneath the car is very limited, and for this reason and also in order to get a more even discharge and avoid any possible trouble arising from the temporary ineffectiveness of one of the valves or other parts, the pump cylinder is made of the piston type—small in diameter, of short stroke, and in a set of three; and hence consists of three double-acting cylinders, each 3¼ ins. in diameter and 2½-in. stroke. Each pump cylinder has at each end one 2¾-in. metal valve, with leather facing, and even at the extremely high speed of 280 r. p. m., which corresponds to a car speed of 25 miles per hour, the velocity of the fluid through the valve seats is not excessive.

When the brakes are off, there is no pressure in the pump cylinders except that due to the friction of the fluid in passing through the valve seats and pipes; and for this reason the latter are also made large so as to reduce this friction to a minimum. When, however, the brakes are put on, the pressure rises perhaps 50 lbs., but the pump cylinders are made strong enough for 100 lbs. or more.



SECTIONS OF PUMP, BRAKE CYLINDER AND CONTROLLER

By reason of the same lack of room as mentioned before, there is not length enough under the car to operate the pump pistons by the usual crank, connecting rod and cross-head, and therefore the action is obtained by means of an eccentric of hard steel secured to the axle and pressing on slides, also of hard steel or bronze, which work in a cross-head, fastened to the piston rod; the whole being immersed in ordinary lubricating oil and contained in a closed tank.

To avoid freezing in cold weather, the working fluid selected is also oil, and a very limpid and white variety has been secured—free from any risk of fire.

From the pumps the oil passes into the brake cylinder, which is the effective part of the whole device, and consists of a lower cylinder, suspended to the bottom of the car by links and containing the brake pistons, and an upper cylinder containing a piston valve. The lower cylinder has two leather-packed pistons, one of which is connected to one brake rod, the other brake rod being fastened to the opposite end of the cylinder itself. The second, or loose piston so-called, is free, and in the ordinary action of the brake is inoperative, being held against the cylinder head by the pressure on the opposite face of this piston.

The brake cylinder has a port in about the middle of its length and extending half way around its circumference, and when the brakes are put on in the regular way, the oil, under pressure, comes in through this port and moves the brake piston, and so brings the brake shoes against the wheels by means of the same levers and rods as are now used in the ordinary hand-brake.

If, however, any accident happens to the pump and the brake piston fails to act, the motorman can force oil from the controller between the loose piston and the cylinder head, in a way to be hereafter described, and so bring the loose piston against the brake piston and put on the brakes by hand.

When the brakes are off the oil from the pumps does not enter the brake cylinder at all, but goes into the upper cylinder instead by one port and passes out of the same by another port, and so goes back to the pump. The upper or valve cylinder has really four ports, viz.:

1. In or about the middle of its length an entrance port *a* from the pump cylinder.

2. At one end an outlet port *c* leading into the brake cylinder between the cylinder head and the loose piston.

3. Between these two an outlet port *b* leading back to the suction of the pump cylinders.

4. In the cylinder head a port *d*, controlled by a check valve, which permits the passage of oil in one direction only. By this port, after the brakes have been put on by hand, the oil is brought back from the brake cylinder to the controller.

When the brakes are off, *a* and *b* are open and *c* is closed. When, on the other hand, the brakes are to be put on in the regular way, *a* is still open, but *b* is partly or wholly closed, *c* also being still closed. Oil is then forced by the axle-pumps into the brake cylinder and pressure is brought on to the fixed piston to move the brakes. If, however, for any reason, the pumps do not act, the motorman can move the piston valve over far enough to open *c*, *a* being still wholly or partly open and *b* still closed. He can thus force oil between the loose piston and the cylinder head and put the brake on by hand in this way, as before stated.

On the other hand, if any accident happens to the controller, or all the oil leaks out of the same, the valve cylinder is provided with a spring, which will force the piston valve back so as to close the port *a*, and the pumps will then force oil into the brake cylinder, and so move the fixed piston, and, in this way again, the car will be stopped automatically.

If for any reason the regular method of putting on the brake is only partially effective, the motorman can assist it more or less

by the hand-power. There are, in fact, four ways of applying the brake without recourse to anything except the single handle or lever in the grasp of the motorman.

1. The regular method, which requires only about one-eighth of a turn of the brake handle.

2. The direct hand-power method, which requires not over four turns of the brake handle to obtain the whole stroke of brake piston, and is likely to be used but rarely, if ever.

3. A combination of the first method with the second to a slight degree.

4. The safety method, which is instantaneous and also of very improbable occurrence.

The controller consists simply of a single-acting cylinder filled with oil and containing a piston fastened to the same rod to which the brake handle is attached. By means of the oil the motorman has a direct connection with the piston valve, and can move the latter, as before mentioned. The parts are so proportioned that the motorman has to exert a force of about 25 lbs. only on the brake handle in order to apply the brake by hand with a force of 50 lbs. per square inch on the brake piston; and in doing this he will have to take not over four turns of the brake handle to obtain the whole stroke of the brake piston; while it will take only one-eighth of a turn to close port *b* and put on the brake in the regular way, as before stated; and this with 5 lbs. only on the brake handle.

The principal advantages claimed for this brake are: The wheels are automatically kept from skidding, thus securing the maximum braking power. As soon as the wheels begin to skid the axle pumps will stop. Oil will then leak out of the brake cylinder through *b* into a reservoir provided. The pressure on the brake shoes will thus be reduced and the wheels started again by the momentum of the car; hence the pumps will start again, and pressure again be brought upon the brake blocks. So long, therefore, as the car moves at all, there will be a pressure upon the brakes.

If the pumps should fail to act, the motorman is still able to apply the brake by exerting his own strength on the brake handle in a way similar to and no more difficult than the present one.

If anything happens to the brake controller, so that the motorman has no command at all over the brake, the latter will be put on automatically and the car can be brought to a stop.

The mechanical and hand-power methods of working the brake are both operated by means of the same hand lever, so that in case of an emergency the motorman is not compelled to turn from his usual appliance to an unaccustomed one in order to stop the car.

The brake can be operated in four different ways, as stated above, and from either end of the car, so that, if the brake controller mechanism gives out at one end, that end can be shut off, leaving the car to be stopped from the other end.

It costs nothing to operate the brake, since there is practically no load on the pumps when the brakes are off, and when they are on the momentum of the car does the work of stopping it.

Test of an "L Special" Truck

A careful test of a Peckham "Elevated Special" double truck was made at the works of the Peckham Motor Truck & Wheel Company, Kingston, N. Y., on June 23, under the supervision of J. F. Morrison, superintendent and engineer of the South Side Elevated Railroad Company, Chicago, Ill.

The test made was of one truck frame, and resulted as follows:

Power applied,	20	tons,	1-8	in. deflection.
" "	30	"	3-16	in. "
" "	35	"	1-4	in. "
" "	40	"	7-16	in. "
" "	45	"	5-8	in. "
" "	50	"	15-16	in. "
" "	55	"	broke in yoke.	

Upon examination of the yoke it was found to be uniformly malleableized throughout, and contained no flaws.

The above test applied to one-side frames would be equivalent to a breaking strain of 110 tons for two-side frames used in the construction of each truck, or 220 tons for one car equipment of two trucks. This test shows that the trucks will safely carry from eight to ten times the maximum weight of the car and load for which they were designed.

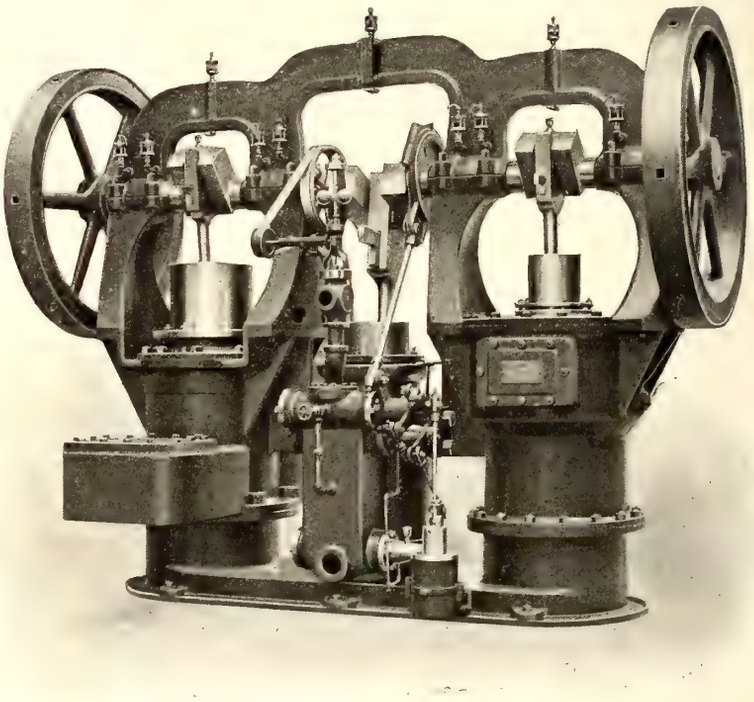
Consolidation of Supply Companies

The charter of the Miller-Knoblock Company, South Bend, Ind., being about to expire, the company has reorganized under the name of the Miller-Knoblock Electric Manufacturing Company, and will continue to make and sell commutators and armature coils.

The company has also consolidated with the Northwestern Electric Manufacturing Company, of Chicago, makers of insulated wire and the plant of the latter company has been moved to South Bend and installed in the commodious plant of the old Miller-Knoblock Company. The new company will, therefore, also produce all sizes of silk and cotton-covered magnet wire, and will make a specialty of coarse sizes of single and double cotton-covered wire for armature winding and field coils.

Combined Air and Circulating Pump

A description was published in the last monthly issue of this paper of the new combined air and circulating pump, recently brought out by the Conover Manufacturing Company, of New York. The accompanying engraving shows a general view of this pump, from which, with the sectional views published last month, a good idea of the arrangement of the various parts can be secured.



COMBINED AIR AND CIRCULATING PUMP

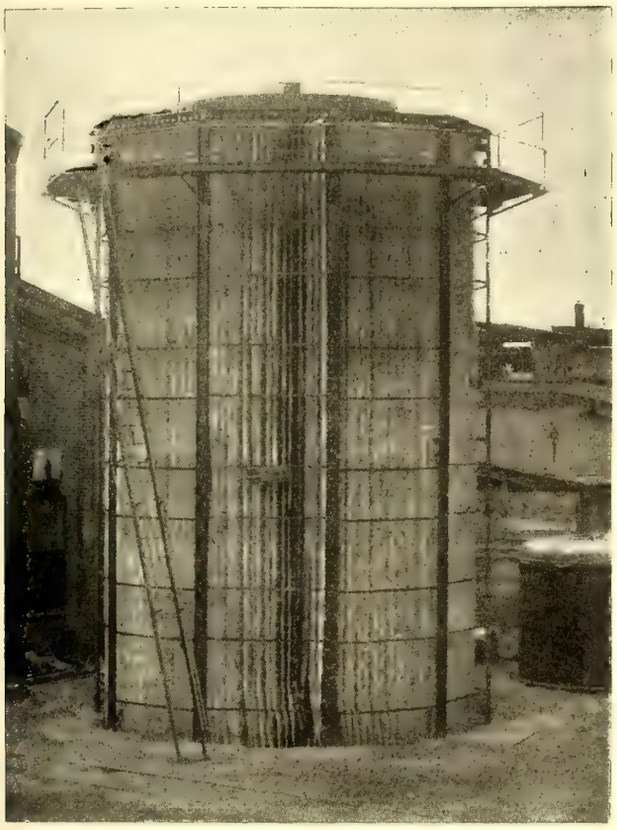
Electric Headlights

The use of electric headlights is growing so rapidly that the accompanying engraving showing the standard type of electric headlight, manufactured by the Dressel Railway Lamp Works, of New York, is of interest. This headlight is made of malleable iron, and is arranged to screw to the front of the dash, in which no hole cutting is necessary. The frame is so designed that the lamp can be easily cleaned or replaced, and is generally furnished with an 8-in. reflector, although it can be supplied with a 10-in. reflector if desired.

The Dressel Railway Lamp Works are one of the oldest manufacturing plants in this country, and have done a very large business in the steam railway field. The locomotive headlights made by this company are very extensively used, and many have adopted the headlight cases as their standard in connection with the Pyle National Electric Equipment. The Dressel Company manufactures nearly all varieties of headlights, signal lights and electroliers used by street railways, and has enjoyed an extensive reputation for the superior quality of its headlights, of which it makes a full line for both electric and kerosene service.

Fanless Cooling Tower

The wide adoption of cooling towers for condensing at points where a large supply of cool water is not available for this purpose has induced the Wheeler Condenser & Engineering Company, of New York, to give special study to the question whether a tower of this kind could not be devised to operate without an artificial draft. As a result of a long series of experiments, the company has finally



FANLESS COOLING TOWER

brought out the tower illustrated herewith, which is capable of giving practically the same result, without motive power, as the company's well-known Barnard inclosed fan-driven system.

The principle involved is the same as in the Barnard inclosed tower (which has been described in these columns), having the same wire cloth mats on which the water to be cooled is sprayed by means of perforated and slotted pipes. The outside shell, peculiar to the fan tower, has been entirely removed, thus leaving the mats exposed to the atmosphere on all sides. The tower is circular in form, with the mats radiating from the center; this arrangements utilizes all the natural air currents, and also those established within the tower itself.

All the mechanical means necessary to circulate air for cooling the water have been dispensed with, thus avoiding wear and tear—always associated with moving or operating parts. The great advantage of this type of tower is the absence of any motive-power requirements, which in turn increases the economy, as well as the general efficiency of the condensing plant.

The water distribution system is so designed that when a varying load is encountered, such as the operating day and night conditions of an electric station, one or more sections of the tower may be shut off. This feature is especially valuable, as any portion may be cut out and repaired or cleansed without interrupting the operation of the balance of the tower.

A gallery surrounds the upper works to facilitate inspection and cleaning when required, every portion of the water distribution system is accessible, and can easily be cleared of foreign matter.

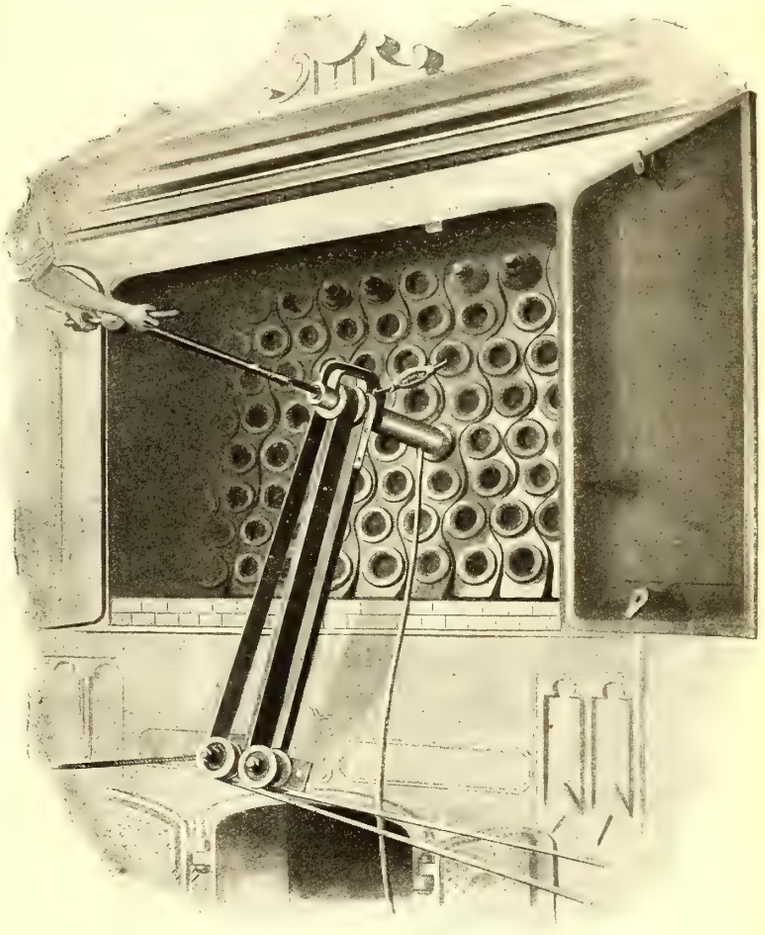
Particular attention has been given to the bracing of the whole structure, to provide against strains or exposure to wind pressures, all parts being of ample dimensions to insure great strength and durability. The fact that the average height of the tower is but 30 ft. recommends itself, especially when the tower must be located upon a roof structure, or in localities subject to high winds. When considering the question of a roof tower, it will be found that the weight per square foot of roof area is very low.

In extreme cases, such as great reductions in temperatures, or with very limited space, the company still recommends the Barnard inclosed fan tower, of which there is some 250,000 hp in use. The tower illustrated has a capacity of about 1000 hp.

Economy in Boiler Cleaning

The Weiland boiler tube cleaner, which is made by the Lagonda Manufacturing Company, of Springfield, Ohio, has been adopted in a number of steam plants with excellent results. A view of the cleaner is shown herewith, and illustrates very clearly the extremely simple manner of attaching and removing it from tube to tube or from one row of tubes to another. The machine itself is driven by either an electric motor, steam, gas or gasoline engine or any suitable power, and the manufacturers recommend about 5 hp, although they have driven it successfully with a 3-hp motor.

In preparing for its use it is only necessary to open the doors and remove the caps from the tubes, as with any cleaner. A platform is built in front of the boiler on which the operator stands. Attached to the cleaner is a swinging board with flange pulleys,



BOILER CLEANER

over which the belt runs, fitted to the bottom of it, and the belt, when the machine is in motion, is held tight. This board swings perfectly free, and it can be drawn down so that the belt is securely tightened when the machine is in motion, and loosened again when the operator desires to change from one tube to another. One man can readily handle it, and the time saved in getting ready to clean boilers is as much almost as is required in cleaning with some other devices.

A series of effective cleaner heads are used, by means of which the scale can be quickly and thoroughly removed from all the tubes, and the manufacturers state they are willing to undertake to remove with this machine the very heaviest scale that can be found in any water-tube boilers, having recently done very successful and satisfactory cleaning where the scale was so thick that only about 1 in. of opening remained. These machines are sold direct to users, or the manufacturers will take contracts for cleaning boilers of any style.

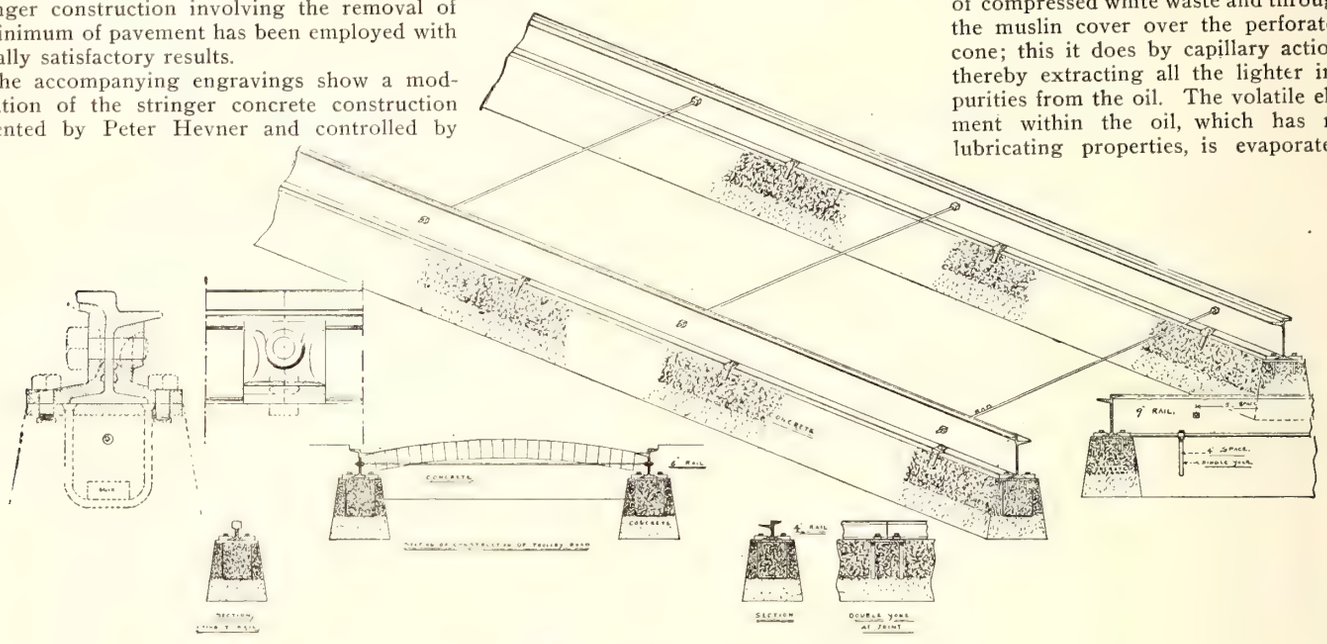
The Meriden, Southington & Compounce Tramway Company, of Meriden, Conn., has recently published a tasteful pamphlet containing views and descriptions of some of the most interesting points along its picturesque line.

Concrete Stringer Construction

The use of concrete without ties in track construction is one of the radical changes in that department of street railway work which have been accomplished since the introduction of electric traction. Concrete sub-construction has been adopted by railways in many of the principal cities of this country, and has proved perfectly satisfactory. In some cases, as is well known, the concrete is carried entirely across the roadbed, but in other cases a stringer construction involving the removal of a minimum of pavement has been employed with equally satisfactory results.

The accompanying engravings show a modification of the stringer concrete construction invented by Peter Hevner and controlled by the Indestructible Roadbed Company, of Philadelphia. As will be seen, the rails rest directly on a concrete prism, the depth of which depends upon the weight of rail, traffic to be carried, etc., and which can be laid in a narrow trench without interfering with the rest of the roadway. The rails are held to gage by tie rods every 4 ft. to 5 ft., as usual. The characteristic feature of the system, however, consists in the employment of U-shaped bolts, which are buried in the concrete when the latter is tamped in the trench, and are fitted with clips which fit over the base of the rail, holding the latter in position. The advantages of this construction over the ordinary construction in which the rail is set in concrete is claimed to be that it is much more easy to replace the rails. To do this it is necessary only to remove the nuts from the ends of the bolts and take out the tie rods, after which the rail can be replaced by an unworn section. The construction has been employed in Syracuse and elsewhere.

If desired, feeder conduits can be laid in the concrete stringer, which is usually 9 ins. wide on top, 13 ins. deep, and 13 ins. in width at the base.



CONCRETE STRINGER CONSTRUCTION

The Famous Oil Purifier

The rights to the Famous oil purifier, which has been employed in many power stations, have recently been secured by the Chicago Boiler Cleaner Company, of Chicago, which is now placing this device on the market. The filter is illustrated in section herewith, and depends for its operation on the use of a low initial heat by means of the air jacket and steam jacket combination embodied in this apparatus.

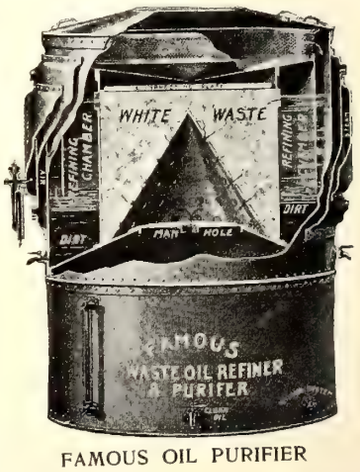
Exhaust or live steam is admitted into the steam jacket at the left-hand side, see engraving. The amount of steam admission is regulated by a globe valve placed in the inlet pipe in a convenient position close to the apparatus. In the drain or outlet of the steam jacket is interposed a water trap, to check the outflow, to insure a positive filling of the steam jacket with steam in the most economical manner. The relief valve prevents injury to the jacket by over pressure, as it opens at less than 1-lb. pressure.

The dirty waste oil is poured or led into the removable strainer, which retains all the coarser impurities; the oil then passes through the large area of fine straining surface (around the removable strainer), then down toward the bottom of the settling and refining chamber; the unsettled oil is always kept away from the filtering material by the deflecting shield which hangs in this chamber.

The proper waste oil refining and purifying temperature is safely and gradually communicated to the oil in the refining chamber by the steam jacket through the air jacket, thereby thinning the oil and making it bright and clear, and all the entrained water, carbon and suspended impurities are separated from the oil and precipitated on the bottom of the settling chamber, when they are readily withdrawn through the dirt faucets. In this manner the waste oil is first thoroughly strained, then positively settled and refined, and fully 90 per cent, it is claimed, of the impurities are extracted from the oil before it overflows into the filtering chamber. The oil then gradually filters through the large area of compressed white waste and through the muslin cover over the perforated cone; this it does by capillary action, thereby extracting all the lighter impurities from the oil. The volatile element within the oil, which has no lubricating properties, is evaporated, thereby refining the oil and making it a higher grade lubricant.

In the jacket system embodied in the Famous the settled and precipitated impurities are not stirred up by circulation, as no heat is applied under, or even near, the bottom.

As the cubic contents of the refining chamber are comparatively small, on account of the displacement by the filtering chamber, and also because the jacket prevents radiation, the initial heat communicated to the dirty oil by the extra large area of low heating surface presented by the jacket is so low that the proper refining and purifying temperature is obtained without injury to the lubricating properities of even the lowest grade of oil, and regardless of cold and hot-water changes.



FAMOUS OIL PURIFIER

The perforated cone presents a large area of filtering surface. The purified oil is delivered cold at the clean oil faucet.

Lifting out the removable strainer by the handles opens the entire refining chamber and filtering chamber, and the filtering material may be inspected or renewed without drawing off any oil or disturbing any part of the apparatus. The straining surface being placed around the side, and not on the bottom of the removable strainer, prevents clogging by the heavy and coarse impurities.

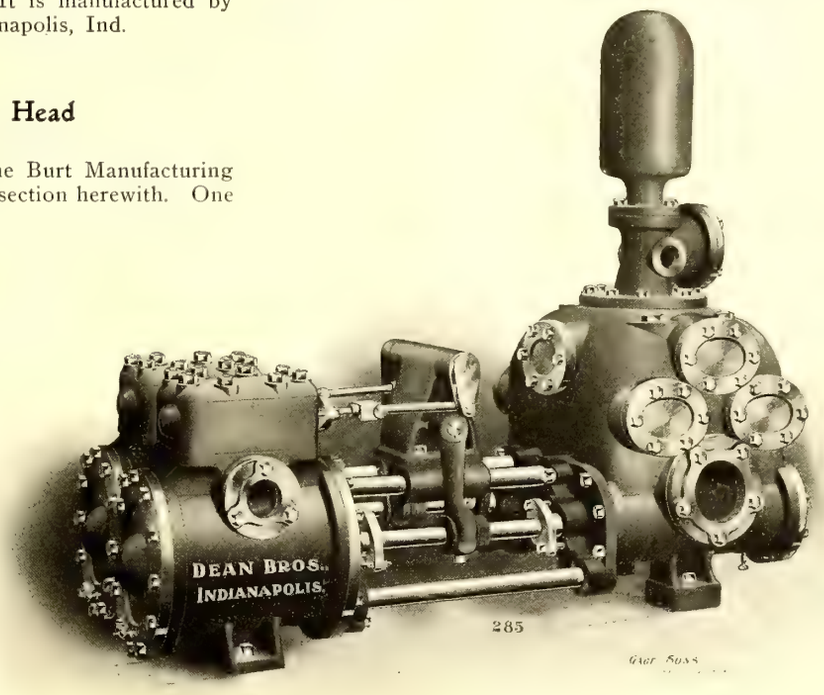
For use where steam is not available, as in rotary sub-stations, a modified form of filter is manufactured, in which the heat is secured by means of electricity. The Chicago Boiler Cleaner Company also supplies, without charge, an oil microscope by which the engineer can determine for himself whether the oil he is using is free from impurities or not.

A meeting of the stockholders of the Cleveland Electric Railway Company will be held on Aug. 9, when a proposition to increase the capital stock of the company from $12,000,000 to $13,000,000 will be voted upon.

A Modern Duplex Pump

The duplex pump has been in use so long that its principles are well understood by most engineers. The accompanying engraving shows the latest development of this type of pumps for heavy pressure and hard service. As will be seen, the steam cylinders and steam chests are heavy and strongly bolted. The frame is made with heavy polished steel stretcher rods. The water cylinders are extra heavy, and are cast in one piece. The hand-holes are large and valves are of moderate size.

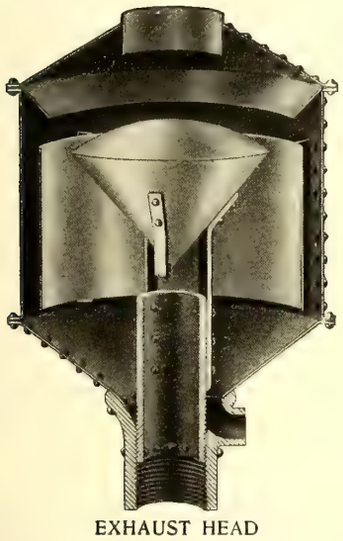
By skillful designing and careful workmanship a pump has been produced that will run under heavy pressure for a long period of time without repairs. The pump shown has 12-in. steam cylinders, 7-in. water cylinders, and 10-in. stroke. It is manufactured by Dean Bros. Steam Pump Works, of Indianapolis, Ind.



DUPLEX PUMP

New Type of Exhaust Head

A new type of exhaust head, built by the Burt Manufacturing Company, of Akron, Ohio, is illustrated in section herewith. One



EXHAUST HEAD

chief feature of the head is the absence of baffle plates. The exhaust steam, after coming in through the pipe, strikes the cone immediately over the inlet. This cone separates the steam into fine particles, condensing some of the vapor. The greater volume of steam rises up to the small projection extending around the top of the head, and is held there for an instant, causing the particles of water and oil to drop by force of gravity down between the double walls on the side and out through the drip below. The use of perpendicular sides gives the maximum cooling surface for the exhaust steam, while nothing but dry steam escapes from the outlet.

The Burt exhaust head is made from extra heavy iron, lapped and riveted.

Convenient Curtain Holder

The Quaker City Car Curtain Supply Company, Ltd., of Philadelphia, has recently brought out a new pinch-handle cable holder for car curtains, which is illustrated herewith, and which is called the Victor holder. The chief claims made for the holder are that it holds the cable tightly and does not slip up, and that it does not wear out. The handle is very easily operated and kept in repair.

The Quaker City Car Curtain Supply Company is a new corporation, having been incorporated May 31, 1900, with Benjamin Conner as president, A. G. Shellenberger as secretary and treasurer, and William Daut as general manager. The company also manufactures curtains of all descriptions.

An Improved Fare Register

The accompanying illustration gives a general view of a register which has lately been designed. It is claimed for this register that it not only contains all the advantages found in similar appliances, together with many more that are peculiarly its own, but that it can be supplied to railway companies at a cost much below the present price of first-class registers. It has been called the "Monarch," and is made both single and double. The appearance of the round bronze case is handsome, and the workmanship of the mechanism within is of the best, although a specially designed bolt prevents the inspection of this latter feature by anyone but the proper authorities. Various ingenious interlocking devices in the trip-register mechanism prevent tampering with the number of fares already rung up, and a perfected "flag" device and catch prevent the bell from ringing except when both trip register and totalizer record. In the double form each register is independent, there being two separate bells of different tone. The case of the double is the same size as the single. Both trip registers count up to 1000 and the totalizer to 100,000. No seal is

NEW FARE REGISTER

used on the case, as the precautions taken to prevent opening, turning back or in any way tampering with the mechanism have been thought sufficient guard against theft. The manufacturers of this new register are Neilsen & Bentson, New York. A. E. Neilsen, of the firm, has had many years' experience with some of the best makers of fare registers in the country, and is, therefore,

able to employ the very best practise in making the Monarch. The Morris Electric Company, 15 Cortlandt Street, New York, controls the device, which is sold only through that company.

The New Works of the Jewett Car Co.

The Jewett Car Company, on March 1, 1900, moved from Jewett to Newark, Ohio, where the company has now almost completed the erection of one of the largest street car manufacturing plants in this country. The buildings and yards are shown on the accompanying diagram, and cover about 10 acres of ground. Seven large buildings are now completed, and a drying kiln and a number of smaller buildings are under construction.

A side track from the Baltimore & Ohio and P. C. C. & St. L. railroads brings lumber to the yards, and gives the best facilities for making shipments of finished cars. At the west of the side track where the car timber is unloaded, is now being erected a very large drying kiln 40 ft. x 100 ft., and near this, on the opposite side of the track, stands a large building for storing dry lumber. Near the dry-lumber building is the machine shop, which is built in "U" shape, fronting 136 ft. on the transfer track. The south wing running back 176 ft. x 48 ft. wide, is equipped with modern heavy car-building machinery. This part of the machine shop is used principally for the heavy work. The north wing extends back 144 ft. x 48 ft., and is equipped with the most modern machinery for getting out interior finish. The rear end of this wing is used as a cabinet room.

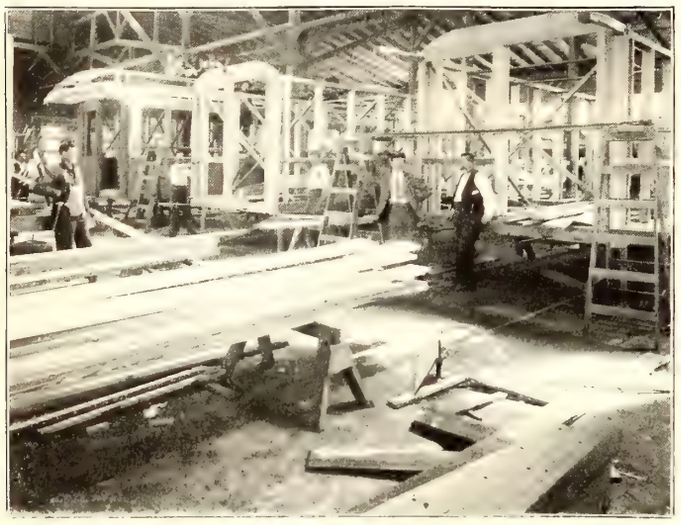
It will be noted that the above arrangement is such as to facilitate the handling of material. Cabinet work is in these departments prepared complete for erection. Between the two wings of this building is a dry kiln used for drying lumber for interior finish. This arrangement brings the finished lumber the nearest possible to the point where it is worked up.

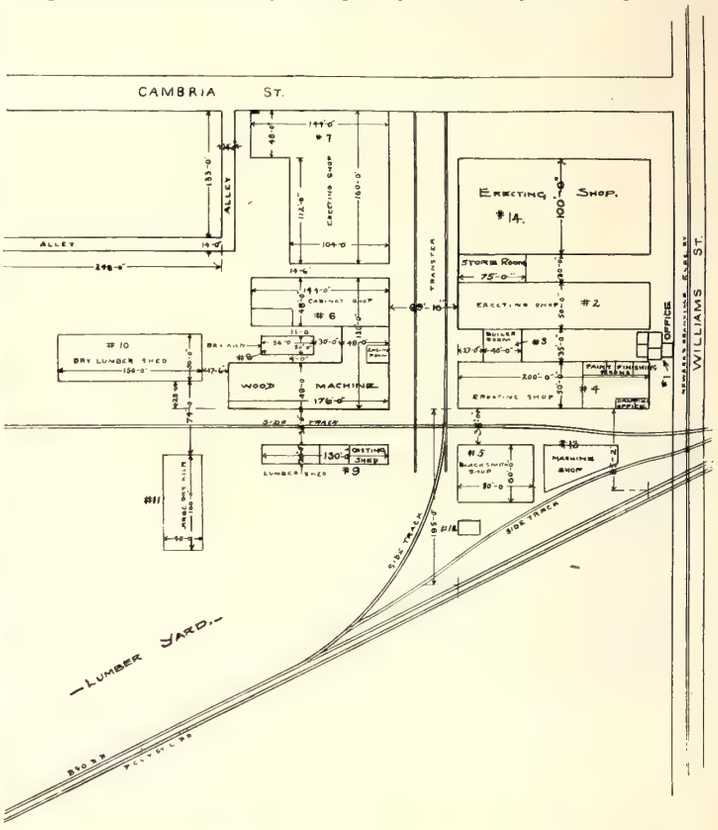
North and in line with the machine and cabinet shop is one of the erecting shops 160 ft. x 104 ft. with a wing 48 ft. square. This building has ten tracks laid in a cement floor. Here the cars are erected and painted ready for varnishing.

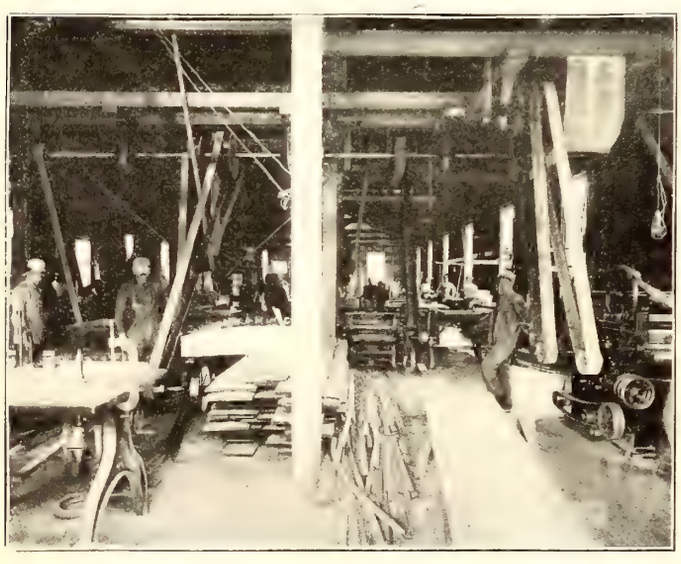
Along the front of the buildings named runs a 70-ft. electric transfer table, which is equipped with electric motor, and so arranged that cars are easily and quickly handled by electric power, either from one department to another or on to trains for shipment. Connecting with the transfer table on the east are two brick buildings, each of which is 50 ft. x 200 ft., roofed with slate. The north brick building is equipped with tracks and has a cement floor, making it practically dust-proof. The cars are transferred into this building for finishing and varnishing.

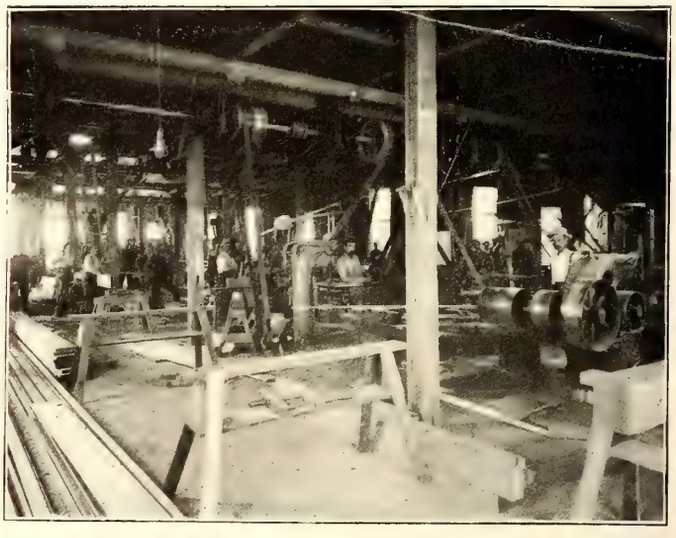
The south brick building is partitioned, half being used for a varnish room, where head linings, sash, etc., are finished. The remaining half of this building, being directly across from the machine shop where the body material is milled out, the lighter parts of the body material are taken to this department to be cleaned up, assembled and stored ready for transferring to the different erecting shops as needed.

At the northeast corner of one of the last-named shops is the









PLAN OF WORKS AND VIEWS IN THE SHOPS OF THE JEWETT CAR CO.

building used for storing bronze trimmings, screws, bolts, nails and other hardware for use in the construction of cars.

Plans are now being completed for another large erecting shop 100 ft. x 200 ft. This will be constructed of pressed brick, with self-supporting roof, covered with slate; it will have seven tracks; four of these will have pits for mounting motors and equipping cars ready for service. This shop will be equipped with an overhead traveling crane.

To the south of the buildings last named is the blacksmith shop 60 ft. x 80 ft., and there is now in course of construction an addition to be used for machinery purposes.

These buildings are so situated, being surrounded by three side tracks, as to make easy the handling and unloading of heavy material from the cars. The blacksmith and machine shop are equipped with the latest improved machinery, such as steam hammers, punches, shears, drill presses, bull dozers, bolt machines, lathes, forges, blowers, traveling crane, and pneumatic hoists.

The plant is complete in every respect. The shops are lighted throughout with electricity, and a complete system of water mains and sewers is now going in, affording ample fire protection, etc. The lumber yards and general yards are equipped with tracks and turn-tables to facilitate the handling of lumber.

The Jewett Car Company has long had an enviable reputation for turning out one of the best-built cars on the market. Now that its plant has grown to be one of the largest in the country, this reputation, backed by the facilities for turning out large orders rapidly, will be of great value. The symmetrical outlines of the company's cars, as illustrated herewith, will suggest to the reader the modeling after steam-coach designs.

The JOURNAL's correspondent found the company's shops crowded with work. Some 400 men are employed, and the force is rapidly being increased.

Among the orders on hand are thirty cars for the Alley L in Chicago, cars for the Steubenville, Mingo & Ohio Valley Traction Company; for Wichita, Kan.; Cincinnati, Lawrenceburg & Aurora; Detroit, Monroe & Toledo; Buffalo & Hamburg, and elsewhere.

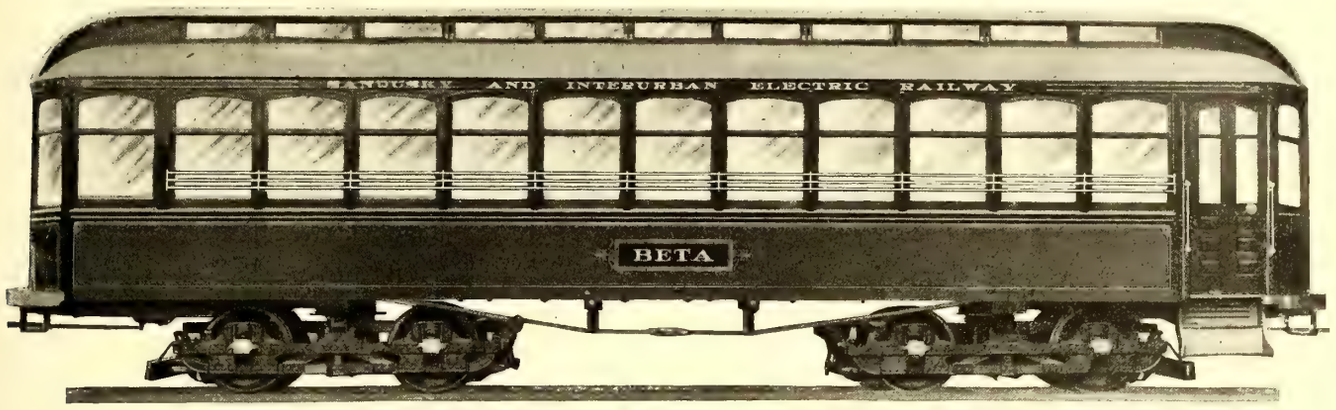
The officers of the Jewett Car Company are: W. S. Wright, president, Wheeling, W. Va.; H. S. Sands, secretary, Wheeling, W. Va.; A. H. Sisson, manager and treasurer; Neil Paulson, superintendent.

Large New Car Wheel Works

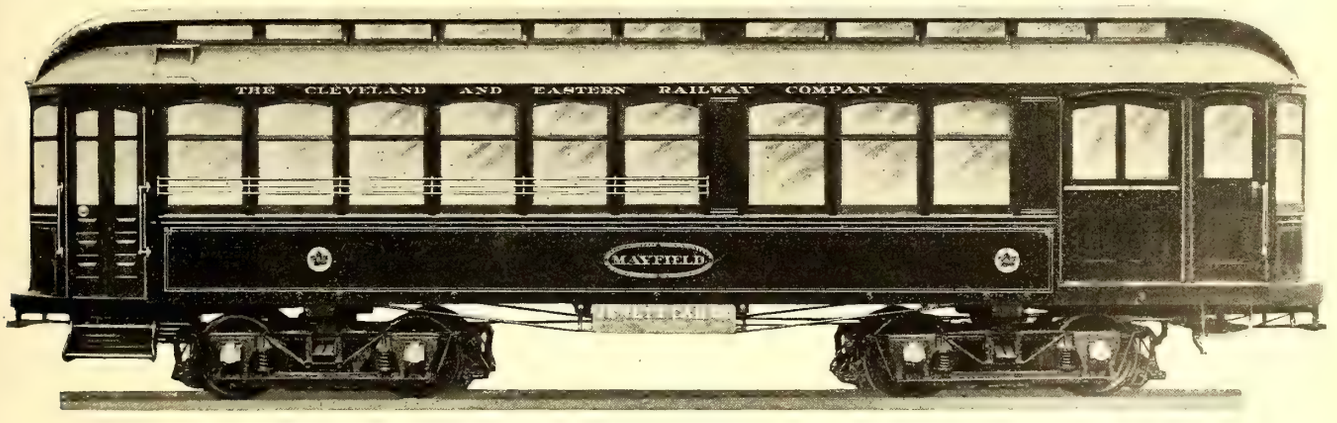
The Keystone Car Wheel Company has been incorporated under most promising conditions, and the works are now in process of construction. The capital of the company is $200,000, and the proposed plant will have a capacity of from 300 to 350 wheels per day. Extensions to the plant, however, can be made with little inconvenience and moderate outlay, as it is confidently expected that the output will soon reach 600 wheels a day. The present plans provide for a foundry and shop containing all the modern labor-saving devices, such as pneumatic hoists, automatic carriers, etc., to be erected near Homestead, Pa. The company has bought an exceptionally fine site of 10 acres on the Monongahela river adjoining the new works of the Haribson-Walker Company. The railroad facilities are extremely good, direct connection being had with the Baltimore & Ohio, Pittsburgh & Lake Erie, Pittsburgh, Virginia & Charleston, and the Union Terminal of the Pittsburg, Bessemer & Lake Erie Railroad. The works will also be within convenient distance of electric lines to Pittsburgh. The main building will be of brick 300 ft. long by 110 ft. wide, so arranged that longitudinal extensions may be made by merely removing the end walls.

The organizers and directors of the company are: Charles V. Slocum, formerly treasurer and manager of the Pennsylvania Car Wheel Company; William L. Elkins, assistant treasurer of the Consolidated Traction Company, Pittsburgh; William W. Lobdell, president of the Lobdell Car Wheel Company, of Wilmington, Del.; Louis B. Whitney, formerly of A. Whitney & Sons, of Philadelphia, the oldest car wheel manufacturers in the United States; Charles A. Otis, Jr., of Otis, Hough & Co., iron and steel merchants, of Cleveland, and son of the former president of the Otis Steel Company.

The officers are: President and general manager, Charles V. Slocum; vice-president, William W. Lobdell; treasurer, Louis B. Whitney, and secretary, John Howard Yardley, formerly vice-president of the Philadelphia Car Wheel Company and one of the organizers of the Pennsylvania Car Wheel Company. The new company has first-class financial backing, and its technical strength is assured by the personnel of the organization. The very best work will be turned out for both steam and electric



LONG CAR FOR SANDUSKY AND INTERURBAN RAILWAY CO.

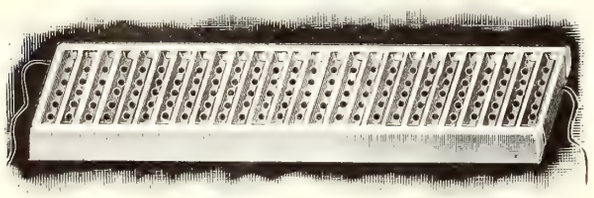


LONG CAR FOR CLEVELAND AND EASTERN ELECTRIC RAILWAY CO.

service, but a specialty will be made of street railway car wheels. President Slocum has always had remarkable success in the car-wheel business. At twenty-five he was business manager for Frederick Stearns & Company, Detroit, leaving that position to become treasurer of the New York Car Wheel Company, Buffalo. He resigned in 1898 to take an active part in the organization of the Pennsylvania Car Wheel Company, with which company he remained until last November. His brother, A. W. Slocum, who has been associated with him in most of his car-wheel ventures, will probably be connected with the new company.

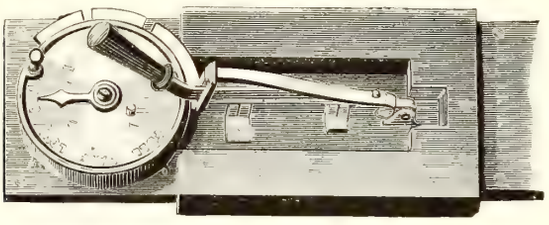
Electric Car Heaters

About this time of year the managers of street railways are looking around for an economical car heater. The National heater, the plate of which is illustrated on this page, is constructed on practical principles, and the manufacturers claim that, although it has a large radiating surface, the space occupied is a minimum.



FRAME OF HEATER

It is made from sheet iron, corrugated, and then heavily coated with white enamel. This assures perfect insulation and prevents deterioration. The heating resistance being imbedded in the enamel, it cannot corrode, or break and ground the heater. The wires are safe from mechanical strain, and as it takes the heater about thirty minutes to cool off after breaking the circuit they are practically under a process of annealing during that period. The



REGULATING SWITCH

heaters are made by the National Electrical Manufacturing Company, which also makes the regulating switch shown in the second cut. This device has a capacity of 25 amps. at 650 volts, and will allow three different degrees of heat to be obtained. Arrangements are made to prevent the operator receiving a shock, and a locking system prevents the changing of the dial until the switch is opened. Both of these specialties are being placed on the market by the Morris Electric Company, New York.

The American Bridge Company

The American Bridge Company has issued the following circular letter to the trade: "As a result of numerous conferences it has been deemed expedient to organize the American Bridge Company, incorporated for the purpose of designing, building and erecting bridges and all classes of metallic structures. The facilities at our disposal are such that we have every confidence that we shall be able to give you the advantage of very favorable quotations, and at the same time be enabled to avoid delays in delivery, which in the past have proved so vexatious in many instances. We solicit your inquiries, which shall have our very best attention."

Below will be found a list of the various bridge companies forming the consolidation, as follows:

American Bridge Works, Chicago, Ill.
Berlin Iron Bridge Company, East Berlin, Conn.
Buffalo Bridge & Iron Works, Buffalo, N. Y.
Carnegie Steel Company (Keystone plant), Pittsburgh, Pa.
Edge Moor Bridge Works, Wilmington, Del.
Elmira Bridge Company, Elmira, N. Y.
Gillette-Herzog Manufacturing Company, Minneapolis, Minn.
Groton Bridge & Manufacturing Company, Groton, N. Y.
Hilton Bridge Construction Company, Albany, N. Y.
Horseheads Bridge Company, Horseheads, N. Y.
Lafayette Bridge Company, Lafayette, Ind.
Lassig Bridge & Iron Works, Chicago, Ill.
New Jersey Steel & Iron Company, Trenton, N. J.
New Columbus Bridge Company, Columbus, Ohio.
Pittsburgh Bridge Company, Pittsburgh, Pa.
A. & P. Roberts Company (Pencoyd Iron Works), Pencoyd, Pa.
Post & McCord, Brooklyn, N. Y.
Rochester Bridge & Iron Works, Rochester, N. Y.
Schultz Bridge & Iron Works, Pittsburgh, Pa.
Shiffler Bridge & Iron Company, Pittsburgh, Pa.
Union Bridge Company, Athens, Pa.
Milwaukee Bridge Company, Milwaukee, Wis.
Wrought Iron Bridge Company, Canton, Ohio.
Youngstown Bridge Company, Youngstown, Ohio.

This list contains all the leading companies that manufacture bridge and structural work in this country, with the combined capacity of 600,000 tons per annum. The Pencoyd plant, of the A. & P. Roberts Company, also comprises one of the best and most complete rolling mills for structural material in existence, with a capacity of 200,000 tons per annum. This puts the American Bridge Company in a position to furnish all classes of bridge and structural work at an absolute minimum of cost, and in the very shortest possible time, and this has already been announced as the future policy of the company. No advance in prices will be made, but the cost of production will be reduced to an absolute minimum, and, judging from the known facilities of the various plants, the facts would seem to justify the statement.

The directors of the company are as follows: Percival Roberts, Jr., A. & P. Roberts Company (Pencoyd Iron Works),Pencoyd, Pa.; Alfred C. Case, Carnegie Steel Company, Pittsburgh, Pa.; William H. McCord, Post & McCord, Brooklyn, N. Y.; Charles M. Jarvis, Berlin Iron Bridge Company, East Berlin, Conn.; William H. Connell, Edge Moor Bridge Works, Wilmington, Del.;Walter Hawxhurst, Elmira Bridge Company, Elmira, N. Y.; Charles Macdonald, Union Bridge Company, Athens, Pa.; Frank Conger, Groton Bridge Company, Groton, N. Y.; James P. Kennedy, Youngstown Bridge Company, Youngstown, Ohio; Lewis S. Gillette, Gillette-Herzog Manufacturing Company, Minneapolis, Minn.; John F. Alden, Rochester Bridge & Iron Works, Rochester, N. Y.; Walter G. Oakman, Guarantee Trust Company, New York, N. Y.; J. P. Ord, General Electric Company, Schenectady, N. Y.; Robert Winsor, Kidder, Peabody & Co., Boston, Mass.; Robert Bacon, J. P. Morgan & Co., New York, N. Y.; Charles Steele, J. P. Morgan & Co., New York, N. Y.; Paul E. De Fere, 40 Wall Street, New York, N. Y.; Robert S. Green, 1 Montgomery Street, Jersey City, N. J.; J. W. Walker, Shiffler Bridge Company, Pittsburgh, Pa.; Abram S. Hewitt, Cooper, Hewitt & Co., New York, N. Y.; August Belmont, August Belmont & Co., New York, N. Y.

The majority of this board are practical bridge men who have in years past made a success of their individual companies. The financial end is unusually strong, being represented by firms and institutions of world-wide financial strength, thus forming a combination of practical and successful bridge men, backed by the strongest of financial resources.

The executive organization is made up entirely of men of large practical experience, headed by Percival Roberts, Jr., one of the leading rolling mill managers of the country. Joshua A. Hatfield has been appointed as assistant to the president, and will also have charge of the sales of the rolling mill products of the Pencoyd plant. The engineering department is in charge of Charles C. Schneider, formerly chief engineer of the Pencoyd Iron Works, of the A. & P. Roberts Company, with the title of vice-president, in charge of engineering.

The operating department is in charge of Charles M. Jarvis, formerly president of the Berlin Iron Bridge Company, with the title of vice-president, in charge of operating. As soon as contracts for any work are taken, they are immediately turned over to this department for execution, and consequently all the plants and erecting forces of the company belong in this department. At each plant is a manager, with full charge over all employees and the operations of that particular plant. All managers are under the direct charge of a general manager, James P. Kennedy, formerly president of the Youngstown Bridge Company. The erecting is also in charge of the operating department, and this is under William Wennas, as superintendent. Mr. Wennas has had full charge of all the Pencoyd erecting for a number of years, and gained a world-wide reputation but a short time ago for the economical and expeditious manner in which he handled the erection of the famous Atbara Bridge.

All the sales of the company are in charge of the contracting department. Railway contracting, highway contracting and structural contracting.

CURRENT NEWS

House Dynamited at St. Louis

A striker or strike sympathizers made a desperate attempt at dynamiting the house at 3750 Evans Avenue, St. Louis, on July 29. No. 3750 Evans Avenue and the adjoining house are conducted as boarding houses for Transit Company employees, and the object of the dynamite thrower was presumably to kill the occupants of the house, as the dastardly act was committed at 2 a. m. Both houses were badly damaged by the explosion, but fortunately none of the inmates was injured. This is one of the most brazen acts of the strike, and was very unexpected, as there have been no serious attempts at violence of late.

Hearing of the Suit of Sutro Brothers Against the Chicago Consolidated Traction Company Adjourned Until September

On July 27 the hearing of the suit instituted by Sutro Brothers, of New York, against the Chicago Consolidated Traction Company, seeking to force an accounting and a cancellation of the $6,750,000 mortgage given by the company on its property, was adjourned by agreement to the September term of the court. It was ordered that in the meantime there should be no transfer of the Chicago Consolidated Traction stock or any action taken effecting the transaction referred to in the bill of complaint.

Mr. Yerkes in London

C. T. Yerkes, of Chicago, has arrived in London, where he has gone to investigate the London transportation question at the request of an English syndicate, which holds franchises under past Parliamentary grants. D. H. Louderbach, of Chicago, representing Mr. Yerkes, is also in London. He arrived there several weeks before Mr. Yerkes, and has been studying the situation, in order to report on the outlook. Mr. Yerkes, in an interview, said: "If London desires a complete system of intramural traffic, I think we can give it. I have come here in an advisory capacity. It may be possible to establish a combination of underground lines in the city connecting with the surface lines outside, and thus afford the traffic facilities so much needed."

Massachusetts Electric Companies Absorb Another Road

At a special meeting of the stockholders of the Massachusetts Electric Companies, held July 30, it was voted to purchase the Lowell & Suburban Railroad and to ratify the purchase of the South Shore & Boston Railway. The basis of exchange of shares of the Lowell & Suburban was two shares preferred and 1½ common of Massachusetts Electric Companies' stock for one share of Lowell & Suburban Railroad. The basis of exchange of the South Shore & Boston was one share preferred and three-quarters of a share of common of Massachusetts Electric for each share of South Shore & Boston. It was also voted to pay the semi-annual dividends in July and January, instead of in June and December, as at present. President Gordon Abbott made the following statement: "The first fiscal year ends Sept. 30, and before the annual meeting on Nov. 7 a full report of the year's operations will be sent in to all the shareholders as follows: Gross earnings, $3,102,518, an increase of $293,053, or 10.4 per cent; operating expenses, $2,132,679, an increase of $44,781, or 2.14 per cent."

Chicago General Railway to the City on Municipal Ownership and Reduced Fares

On July 23, Charles L. Bonney, general counsel of the Chicago General Railway Company, laid before the Street Railway Commission a series of resolutions adopted by the directors of the company relating to the question of municipal ownership, and also to the specific condemnation of tracks owned and operated by the existing companies. One of the main features in Mr. Bonney's communication to the commission was a direct offer by his company to carry passengers between the Illinois Central Depot at Twelfth Street and the Chicago & Northwestern Depot at Wells Street, for 3 cents; also to carry trunks and packages for 20 cents each, on condition that the city authorities aid in securing permission for the Chicago General cars to run between the points named. Mr. Bonney is also authorized to secure legal adjudication of the right of his company to the use of the Chicago City Railway's tracks on Wabash Avenue, from Twenty-Second Street to Madison Street. General Counsel Bonney holds that by the ruling of the Supreme Court the exclusive right of any corporation to maintain ownership in the city's streets can be set aside at the behest of the people's law officers. The Chicago General's ultimate aim is to get terminal facilities in the downtown district.

Electrical Tramways in Barcelona

The United States State Department has received the following communication from Consul-General Lay, of Barcelona, regarding the electric tramways there:

"I give below the names of the directors and chief contractors of a tramway line about to be built between Barcelona and Horta, a distance of 4 miles. The name of the branch line will be the Barcelona & San Andres Railway, work to be commenced in June.

"Builders, Société Anonyme d'Entreprise Générale de Travaux at Liege, Belgium.

"President, Mr. Laloux.

"Director-General, Mr. Thouet.

"The chief contractor is F. H. Bagge, 14 Ronda Universidad, Barcelona, who imports his trucks, tubing for posts, and motors from the United States.

"The wire is to be supplied by Felten & Guilleaume, of Mulheim; rails, from Belgium; car motors, by General Electric Company, Paris; gas engines, Crossley, of Manchester; cars, from Saragossa, Spain; accumulators, Tudor; dynamos, Industrial Electrico, Barcelona.

"I find it very difficult to get any reliable information about projected roads, especially about those for which the equipment is being bought, as the directors, chief engineers and other officials of new tramways are foreigners, and have their headquarters in other cities. I would suggest, therefore, that our manufacturers write the Société Anonyme d'Entreprise Générale de Travaux, Liege, Belgium, in good time before the contracts are let at Brussels. The society is a very large one, and has built many miles of tramways in Europe, and is constructing lines in Russia, I understand, at the present time.

"In connection with the sale of electrical supplies and equipment in Barcelona, I would advise manufacturers of motors not used in connection with tramways and other small electrical appliances that their agents here must keep a certain stock of such articles on hand, as I am informed by several electrical importers of Barcelona that frequently English or German goods are sold because the purchaser cannot wait for better American-made articles, which take so long to come from the United States."

Report of the Interstate Commerce Commission

The Interstate Commerce Commission has just issued its twelfth annual report. This report gives some very interesting statistics of railways in the United States for the year ending June 30, 1899. From these statistics it seems that on June 30, 1899, the total single-track railway mileage in the United States was 189,294.66 miles, an increase during the year of 2,898.34 miles being shown. This increase is greater than for any other year since 1893. Practically all of the railway mileage of the country is covered by reports made to the Commission, the amount not covered being 1,759.98 miles, or 0.93 per cent of the total single-track mileage. The aggregate length of railway mileage, including tracks of all kinds, was 252,364.48 miles.

The number of railway corporations included in the report on the Statistics of Railways in the United States was 2049. Of this number, 1064 maintained operating accounts, 843 being classed as independent operating roads and 221 as subsidiary roads. The operated mileage of roads merged, reorganized, or consolidated during the year was 5846.35 miles. The corresponding figure for 1898 was 7220.42 miles.

EQUIPMENT

There were 36,703 locomotives in the service of the railways on June 30, 1899, or 469 more than the year previous. Of the total number reported, 9894 are classed as passenger locomotives, 20,728 as freight locomotives, 5480 as switching locomotives, and 601 are not classified.

The total number of cars of all classes in the service of the railways on June 30, 1899, was 1,375,916. Of the total number, 33,859

are assigned to the passenger service, 1,295,510 to the freight service, and 46,556 to the direct service of the railways. It should be understood, however, that cars owned by private companies and firms used by railways are not included in the returns made to the Commission. It appears that the railways of the United States used on the average 20 locomotives and 734 cars per 100 miles of line; that 52,878 passengers were carried, and 1,474,765 passenger-miles accomplished, per passenger locomotive; and that 46,303 tons of freight were carried, and 5,966,193 ton-miles accomplished, per freight locomotive. All of these items show an increase when compared with corresponding items for the preceding year ending June 30, 1898.

The number of persons employed by the railways of the United States, as reported on June 30, 1899, was 928,924, or an average of 495 employees per 100 miles of line. As compared with the number employed on June 30, 1898, there was an increase of 54,366, or 21 per 100 miles of line. From the classification of these employees it appears that there were 39,970 enginemen, 41,152 firemen, 28,232 conductors, and 69,497 other trainmen. There were 48,686 switchmen, flagmen and watchmen. The compensation of the employees of railways for 1899 represents 60 per cent of their operating expenses, and 40 per cent of their gross earnings.

The amount of railway capital outstanding on June 30, 1899, was $11,033,954,898. This amount assigned to a mileage basis represents a capitalization of $60,556 per mile of line. Of this amount of capital $5,515,011,726 existed in the form of stock, of which $4,323,300,969 was common stock and $1,191,710,757 preferred stock. The amount which existed in the form of funded debt was $5,518,943,172. This amount of funded debt was classified as mortgage bonds, $4,731,154,376; miscellaneous obligations, $485,781,695; income bonds, $260,048,753, and equipment trust obligations, $42,058,348. The amount of current liabilities not included in the foregoing capital statement was $554,330,022, or $3042 per mile of line.

The amount of capital stock paying no dividend was $3,275,509,181, or 59.39 per cent of the total amount outstanding. The amount of funded debt, excluding equipment trust obligations, which paid no interest, was $572,410,746. Of the stock-paying dividends 11.91 per cent of the total amount outstanding paid from 1 to 4 per cent, 7.84 per cent paid from 4 to 5 per cent, 7.41 per cent paid from 5 to 6 per cent, 4.21 per cent from 6 to 7 per cent, and 5.18 per cent from 7 to 8 per cent. The amount of dividends declared during the year ending June 30, 1899, was $111,009,822, which would be produced by an average rate of 4.96 per cent on the stock on which some dividend was declared. The amount of mortgage bonds paying no interest was $374,460,358, or 7.92 per cent; of miscellaneous obligations, $70,422,403, or 14.50 per cent, and of income bonds, $127,527,985, or 49.04 per cent.

The number of passengers carried during the year ending June 30, 1899, as shown in the annual reports of railways, was 523,176,508, showing an increase for the year of 22,109,827.

The average revenue per passenger per mile for the year ending June 30, 1899, was 1.925 cents. The revenue per ton of freight per mile was .724 cent.

For the year ending June 30, 1899, the gross earnings from the operations of the railways in the United States, covering an operated mileage of 187,534.68 miles, were $1,313,610,118, being $66,284,497 more than for the preceding fiscal year. The operating expenses were $856,968,999, the increase in this item being $38,995,723.

The income from operation, or the amount of gross earnings remaining after the deduction of operating expenses, generally designated as net earnings, was $456,641,119, an increase as compared with the year ending June 30, 1898, of $27,288,774. The average amount per mile of line for 1899 was $2435. The amount of income received from sources other than operation was $148,713,983. This amount covers the following items: Income from lease of road, $96,352,295; dividends on stocks owned, $20,104,521; interest on bonds owned, $11,334,690; miscellaneous income, $20,922,477. The total income of the railways, $605,355,102—that is, the income from operation increased by the income from other sources—is the item from which fixed charges and analogous items are deducted in order to reach the amount available for dividends. Total deductions from income amounted to $441,200,289, leaving $164,154,813 as the net income of the year available for dividends or surplus.

The amount of dividends declared during the year, including $80,114 other payments from net income, was $111,089,936, leaving as the surplus from the operations of the year $53,064,877, the corresponding surplus for the year ending June 30, 1898, being $44,078,557.

The total number of casualties to persons on account of railway accidents during the year ending June 30, 1899, was 51,743. The aggregate number of persons killed as a result of railway accidents during the year was 7123, and the number injured was 44,620. Of railway employees 2210 were killed and 34,923 were injured during the year covered by this report.

Street Railway Legislation in Massachusetts

The Massachusetts Legislature, which has just adjourned, enacted a large number of street railway measures. It may be said, however, that with one or two unimportant exceptions, no legislation was passed which was particularly inimical to the street railway interests of the Commonwealth. The enactment of the street railway act of 1898 has resulted in so much that was laudable that it has been found necessary to make no very serious changes in general laws.

Perhaps the most important bill passed was that requiring all street railway cars, purchased, built or rebuilt, to inclose their platforms during January, February, March, and October, November and December. A provision was added by the street railway committee, which exempts the city of Boston from the operation of the act, unless after a hearing the Railroad Commissioners decide that public safety will not be endangered by the use of vestibule cars.

A bill was passed which permits the Metropolitan Park Commission to grant locations in public reservations for metropolitan boulevards, parkways, etc.

A large number of bills were offered on petition to permit the formation of street railway freight companies. All of these bills were adversely reported by the committee, however, and in their place a bill was reported to provide that all street railway companies might become general carriers of merchandise, baggage and freight, subject to the same liabilities and restictions as pertain to railway corporations. This general bill was not desired by the street railway companies, as a whole, and as a result all attempts to substitute bills for special railway freight companies were defeated and the general bill was itself killed.

A bill was passed to provide that all uniformed letter carriers should be furnished free transportation on street railways.

Another bill passed provided that every street or elevated railway company shall transport scholars of the public schools, traveling to and from school, at a rate not exceeding $2.50 for one hundred rides. The companies now furnish one hundred tickets for $3, and it is proposed to test the constitutionality of this act, by proceedings brought by some bondholder of one of the larger roads against the corporation.

A compulsory bill was enacted to give the new Plymouth & Sandwich Street Railway Company the right to run upon the tracks of the Plymouth & Kingston Company, the Railroad Commissioners to determine the terms, conditions and compensation if the interested corporations fail to agree.

An attempt was made by several municipalities to secure the repeal of the Street Railway Act of 1898, or else the repeal of that portion of it which provides that municipalities must clear snow and ice from the streets through which the tracks run, but all these attempts proved abortive.

A resolution was enacted providing that the Railroad Commissioners shall consider the matter of requiring street railway companies to pay a proportion of the cost of the abolition of grade crossings in certain cases. This resolution was reported as a substitute for a bill which provided that the street railway companies may pay 5 per cent in all cases.

There was a disagreement over permitting the Webster & Worcester Street Railway Company to act as a common carrier of baggage, express and mail in the city of Worcester, in the towns of Auburn, Oxford and Webster. The matter finally went into the hands of a conference committee, which failed to agree, and therefore the bill fell through.

The law in relation to the use of street sprinkling apparatus on electric railways was amended so that the companies themselves can operate these cars in certain cases.

A bill was passed permitting the Amesbury & Hampton Street Railway Company to lease its roads and property to the Exeter, Hampton & Amesbury Street Railway Company, a foreign corporation.

There was a great deal of discussion over the joint use of tracks by railway companies entering Boston, the attempt being to secure compulsory legislation which would permit the new Boston & Worcester road to enter the city of Boston through Brookline. The bill, which was reported, was favored by all the Massachusetts companies, excepting the Boston Elevated, which opposed it on the ground that there would be great congestion in Boston, if outside railways were permitted to come within the 5-cent limit.

The result was that a general bill was passed, applying to all outside cities, but that the city of Boston was exempted.

The West Roxbury & Roslindale Street Railway Company was authorized to purchase the franchise and property of the Hyde Park Electric Light Company. The result of this is to permit this company to go into electric lighting.

A general bill was passed permitting receivers to sell the property, locations and franchises of street railway companies. There was quite an opposition to this measure, on the ground that a franchise was something which should revert to the municipality in case a street railway became insolvent, but the opposition was futile.

The time for building the Boston, Quincy & Fall River Bicycle Railway was extended to Dec. 31, 1901. If 20 miles are built by that time, all rights of the company shall be extended for one year more, in order that the full line may be completed.

The Lexington & Boston Street Railway Company was given permission to operate over private property in Billerica, Bedford and Lexington.

The Greenfield & Deerfield Street Railway Company was incorporated, notwithstanding the very earnest protest against such action by sentimentalists, who feared that the beauty of the main street of Deerfield would be effected by the location of a street railway through it.

A bill was passed which permits the Boston Elevated Company to have the right of appeal if dissatisfied with the estimate of the County Commissioners or the Aldermen of Boston as to damages for takings in constructing their road.

Among the street railway companies incorporated were the Phillipston Street Railway Company, to operate in Athol, Phillipston and Templeton; the Worcester & Gardner Street Railway Company, to operate in Worcester, Holden, Rutland, Hubbardston, Gardner, West Boylston and Princeton; the Winchendon Street Railway, to operate in that town only; while the town of Sunderland was permitted to subscribe for capital stock of bonds of the Amherst & Sunderland Street Railway Company, which was given an extension of time in which to construct in Sunderland.

A number of street railway companies were given permission to act as common carriers of parcels, United States mail, etc., among them the Gardner, Westminster & Fitchburg; the Palmer & Monson, the Norton & Taunton, and the Interstate Consolidated.

Patent Decision on Trucks

An important decision was rendered last month in the Circuit Court of the United States for the Southern District of New York in the case of John A. Brill vs. Third Avenue Railroad Company. The suit was brought for the infringment of claims 1, 2, 9, 10, 11, 12, 14, 17 and 27 of letters patent No. 478,218, applied for June 26, 1891, and issued on July 5, 1892, to George Martin Brill for an improvement in car trucks. These claims are as follows:

1. In a motor truck, the combination, with a stationary frame supported upon the running gear, said frame having sections extending outwardly from the axle, of a movable frame supported upon said truck, spiral springs located between the movable and stationary frames, and elliptical springs located between the extended sections of the said rigid frame and movable frame, substantially as described.

2. In a truck, a spring-supporting frame supported upon the running gear by saddles and having sections extending outwardly from the axles, a movable frame having like extensions, spiral springs located between the saddles and movable frame, and elliptical springs located between the spring-supporting frame and the movable frame, substantially as described.

9. In a truck, the combination of two frames, one stationary and supported upon the running gear, the other movable, and a plurality of springs located between the stationary and movable frames, some of said series being adapted to be compressed by the downward movement of said movable frame subsequent to the compression of other of the series, substantially as described.

10. In a truck, the combination of two frames, one stationary and supported upon the running gear of the truck, the other adapted to be moved toward said stationary frame, springs located between the ends of both frames, and springs otherwise disposed between the two frames, the end springs being adapted to be compressed subsequent to the compression of the other springs, substantially as described.

11. In a truck, a stationary spring-supporting frame having at its ends elliptical springs rigidly secured thereto, in combination with a movable frame supported by springs other than said elliptical springs, said movable frame being provided with devices for engaging said elliptical springs, the elliptical springs being adapted to be brought into action subsequent to the springs supporting the movable frame, substantially as described.

12. In a truck, a spring-supporting stationary frame mounted on the running gear of said truck, said frame being composed of a plurality of bars contiguously disposed, a saddle secured to the outer sections of said bars, an elliptical spring, the lower section of which rests upon said saddle, and a second saddle disposed over the first, and the spring secured to the first saddle, a movable frame, spring supported upon the stationary frame and having devices for guiding the upper section of the elliptical spring, substantially as described.

14. A truck having running gear and a frame, and spiral springs for supporting the car body, supplemented by elliptical springs adapted to co-act therewith, the spirals being adapted to be compressed prior to the ellipticals, substantially as described.

17. The upper chord having the depending cap 45, with downwardly extending legs 46, and elliptical springs held on the side beams, adapted to move in said cap, substantially as described.

27. In a truck, a stationary spring-supporting frame mounted on the running gear of said truck, having outwardly extending sections and elliptical springs secured to the stationary frame, and a movable frame, having a device for guiding the upper portion of the elliptical springs, substantially as described.

One hundred and eighty-one infringing trucks were purchased by the defendant from the Bemis Car Box Company, of Springfield, Mass., which, it is admitted, "is defending the present suit for the Third Avenue Railroad Company."

The decision was rendered by Judge Shipman, and is quite an extended one.

After reviewing the difficulties of supporting a long car on a short wheel base, the judge says: "The gist of the invention consisted in combining with frames of the truck and the spiral springs another class of springs, viz., elliptical springs, between the car body and the extensions of the independent frame. The elliptical springs are slower in their action than the spiral springs, and neutralize the longitudinal oscillation of the car body. Mr. Akarman, a practical trolley railway superintendent, stated the result and the reason of it, as follows: 'From a practical observation my opinion is that the combination of an elliptic and spiral spring, as applied in trucks of this type, breaks the rhythm of motion or interrupts it. In trucks with all spiral springs, or, I should think, if it were possible to construct a truck having all elliptic springs, the rhythm of motion is perfect, the springs acting in unison. In the truck, as previously described having the combination of elliptic and spiral springs, the rhythm is broken and the result is that the galloping or rocking motion is done away with.'

"This leading feature of the invention is described in claims 1 and 2, which do not contain the limitations of the invention described in the next paragraph. A second and minor feature of the invention described in claims 9, 10, 11 and 14, is such an arrangement of the elliptical springs with the car body that they 'will not come into play until after the axle-box springs have begun to compress, and the action of the spiral springs in lifting the car body is continued after the elliptical springs have ceased to act.' The elliptical springs are not depressed until the car body or one end of it has become depressed by the weight of the passengers or some other cause, when this slower motion interposes and checks the continuation or increase of oscillation.

"Upon the question of the novelty of the invention described in claims 1, 2, 11, 12 and 14, the defendant's expert puts great stress upon letters patent No. 409,993, dated Aug. 27, 1889, to Benjamin F. Manier. One object of Manier was to prevent oscillation, and to accomplish it he employed an extended spring base and mounted the body springs forward of the axles. He said that oscillation was noticeable in cars mounted on trucks wherein the body springs are on both sides of the axles and near the center of the truck, and that the mounting of the body springs forward of the axles he considered a special feature of his invention. The springs, or the kind of springs, which he was to use, are no part of his invention. He says: 'Preferably I employ spiral springs *G*, as shown in Fig. 1 for supporting caps *I*, but, if desired, the elliptic spring *g* could be employed, as shown in Fig. 3, or other forms of springs may be used as found convenient and desirable, the particular form of spring not forming part of present invention.' Manier's invention was entirely apart from that of Brill, and had no conception of its character. The only ground upon which the expert can place his theory is that in Fig. 3, the two different forms of springs, spiral and elliptic, are shown, and upon this drawing the entire superstructure of anticipation is built. Manier's invention was not designed, nor adopted, nor used for the performance of the function performed by Brill's device, nor was the way to accomplish Brill's result suggested by Manier's invention." —(Topliff vs. Topliff, 145 U. S., 156.)

The judge then refers to earlier patents claimed by the defendants to anticipate the Brill patent, notably the Bird, Diehl, Vose and Peckham patents, but these were held by the judge not to be anticipations. He then concludes:

"The only remaining question is that of patentable novelty. It has already appeared that the gist of the invention is described in claims 1 and 2. The necessity for a remedy against the pounding of the car, the importance of the result, the adoption of the invention by experienced railway superintendents, the number of previous attempts at a remedy and the barrenness of their results go far to show that the work of an inventive mind was required and was active in the invention. The testimony of the defendant's expert itself, as he goes through the history of the art and thereby points out what the patentee's combination did, as compared with previous efforts to do something, shows that the patented improvement was patentable. The result of the minor invention of claims 9, 10, 11 and 14 was important, although upon first inspection its marked importance does not appear, but it perfected the general invention of the first two claims. The combination shown in claims 12 and 27 was patentable. The simple combination in claim 17 of the uppper chord, with its depending cap and down-

wardly extended legs and elliptical springs, does not appear to me to have have been patentable.

"Let there be a decree, with costs, for an injunction against the infringement of claims 1, 2, 9, 10, 11, 12, 14 and 27, and for an accounting if it is asked for."

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED JULY 22, 1900.

654,274. Railway Switch; M. O'Dowd, Chillicothe, Ill. App. filed Oct. 27, 1899. The invention comprises a pitman and tie-bar, the tie-bar being provided with a wrist pin, while the other member is provided with a hole to receive the wrist pin. The pitman is provided with a hooked nose adapted to enter a recess in the tie-bar, the nose and recess being so shaped that the pitman can rotate about the axis of the pin within the required range for the operation of the switch without causing a separation between the nose and the recess. This coupling is intended to dispense with bolts and nuts.

654,327. Automatic Switch; T. S. Savage, Oakland, Cal. App. filed April 19, 1900. The switch point is held in one position by a spring; the car wheel depresses a lever and moves the point against the spring.

654,348. Trolley Harp; E. G. Johnson, Brigantine, N. J. App. filed Feb. 16, 1900. The wheel is mounted on an elongated axle, along which it may assume any position, a tendency to run in the middle of the axle being supplied by springs bearing against each side of the wheel.

654,352. Car Seat; W. M. Norcross, Philadelphia, Pa. App. filed May 6, 1899. The back, seat and a foot rest on each side are connected with each other by a system of levers, which effects the adjustment of each part to its proper position when the back is shifted from one side to the other.

654,448. Trolley Base; H. S. Goughnour, Johnstown, Pa. App. filed Sept. 23, 1899. An arrangement of torsion springs with the base of the pole whereby a "low" base is obtained.

654,452. Railway Frog; C. F. Kress, Jr., Johnstown, Pa. App. filed Dec. 28, 1899. A railway frog composed of girder-rails and a central metal chock cast to said rails, said rails having their head portions fitted and abutted to form the entire wear surface of the frog, and the cast metal chock filling the entire space between the underneath abutted portions of said rails.

655,574. Trolley Track for Electric Railways; V. Koch, Scranton, Pa. App. filed Feb. 24, 1900. A crossing constructed from a circular plate integrally made with projections thereon corresponding to the ends of the rails of the trolley track, and adapted to be joined therewith for the purpose of completing the electrical circuit through the said track.

New Publications

Derrah's Official Street Railway Guide of Eastern New England. 248 pages. Illustrated. Price (by mail), 20 cents. Published by Robert H. Derrah, 53 Devonshire Street, Boston.

The excellent work which Mr. Derrah is doing in developing the trolley excursion business in New England should form a model for similar efforts in other parts of the country. Mr. Derrah has shown how the publication of a well illustrated and excellent guide book, showing how interesting points can be visited by trolley, running times of the cars, fares, etc., will, to use a very old expression, fill a long-felt want. The guide for this year is the fifth annual of its kind to be issued by the publisher, and contains a fine portrait of H. M. Whitney, who, as the author says, is largely responsible for the commercial development of the trolley system. It also contains an excellent map of Eastern New England with the trolley lines. The guide is published with the approval of the street railway managers, whose traffic must undoubtedly be largely stimulated by its publication.

PERSONAL MENTION

MR. W. BARRON, manager and purchasing agent of the Brantford Street Railway Company, of Brantford, Ont., is dead.

MR. ROBERT DUNNING, formerly master mechanic for the Buffalo Railway Company, has been appointed master mechanic for the Washington Traction & Electric Company, of Washington, D. C.

MR. J. J. COLEMAN, formerly general manager of the St. Louis Transit Company, has been appointed assistant to the president of the Washington Traction & Electric Company, of Washington, D. C., to superintend the operation of the lines in the district.

MR. C. O. BRUNNER, treasurer of the Bethlehem Iron Company and Bethlehen Steel Company, completed, on July 12, his fortieth year of service. The occasion was marked by the presentation to Mr. Brunner of a silver pitcher and salver and a handsome cane from his fellow members of the staff of the two companies.

NEWS NOTES

LITTLE ROCK, ARK.—The City Council has adopted the Mayor's recommendation in regard to the operation of the Little Rock Traction & Electric Company, and has also adopted a resolution providing that if the company does not comply with the charter, relative to putting the system in first-class order within ninety days, that the Council will proceed at once to nullify the franchise and declare the property a public nuisance. The Mayor's message to the Council was as follows: "I deem it my duty to urge upon you the necessity of taking some decided action relative to the franchise of the Little Rock Traction & Electric Company. The numerous derailments and the inconvenience to and the hardships imposed on the general public July 4, because of the very poor physical condition of its force and rolling stock, has caused such universal condemnation that it amounts to a demand upon us to take action, inasmuch as all former petitions to this company have been ignored. I would therefore recommend that the city attorney be instructed to apply to the United States Court to have the receiver make the necessary improvements within a reasonable time, and in the event this is not done that he at once take steps as may be necessary looking to the annulment of the contract between the city and said street railway company."

BRIDGEPORT, CONN.—The fare between Bridgeport and New Haven via the Bridgeport Traction Company's and the Winchester Avenue Company's lines is to be reduced to 25 cents. At present it is 35 cents, pay as you go, or 30 cents if you buy your ticket in advance.

BRIDGEPORT, CONN.—The Bridgeport Traction Company is now repainting and overhauling its entire winter rolling stock. A force of forty men are employed on the work, and the work will be completed by the season for the withdrawal of the open cars. The body of the cars being redecorated is painted a medium chrome yellow, while the lower portion under the windows is a cream white. Upon this is inscribed the words "Bridgeport Traction Company." The platform gear and trucks are Venetian red, while the body is finished with heavy stripes of deep orange and narrow lines of Tuscan red and black. The car number is in silver, shaded in Tuscan red.

WASHINGTON, D. C.—A car of the City & Suburban Railway jumped the track at the corner of Second and R Streets northeast on July 21, injuring several persons.

WASHINGTON, D. C.—Since the fatal accident to one of the city firemen, due largely to the electric cars stopping on the far side of crossings, the question of reverting to the old plan of stopping on the near side has been considerably agitated by the local press and the citizens, and there is a strong probability that the District Commissioners will shortly issue a notice to the effect that the electric cars will stop at all street cossings on the near side.

WASHINGTON, D. C.—The District Commissioners lately transmitted to the street railway companies here a list of proposed stopping places for the street cars on certain routes taken by the apparatus of the fire department in answering alarms of fire. The companies have replied to these communications, setting forth their reasons for not stopping at some of the points designated by the Commissioners, and agreeing to stop at the others. The exceptions noted are all based on excellent reasons, and no doubt the Commissioners will agree with the street railway companies and modify their requests accordingly.

ATLANTA, GA.—The Atlanta Railway & Power Company is now giving transfers on its lines up to 11 p. m. Heretofore no transfers have been issued after 8 p. m.

LA SALLE, ILL.—The City Electric Railway Company and the city officials are at loggerheads. The authorities have prevented the company from erecting new poles along its route, and have also tampered with the company in other respects. J. R. Burrows, as receiver for the company, is seeking an injunction to prevent further interference with the operations of the company.

CHICAGO, ILL.—A fire in one of the cars of the South Side Elevated Railroad Company on July 14 came very near causing a serious disaster. Soon after the train, carrying 150 passengers, left Eighteenth Street, fire was discovered in the center of one of the cars, and the passengers immediately became panic stricken, despite the efforts of the guards to quiet their fears by telling them that the fire was nothing more than smoke arising from a blown out fuse. Many passengers attempted to jump from the train, but were restrained by the guards, who assured them that the fire would not get beyond control even if it could not be put out.

Akron Power House Badly Damaged by Fire

The Northern Ohio Traction Company's new Akron power house was badly damaged by fire July 29. The loss will probably exceed $35,000. The fire started in the boiler room, where an exploding flue in one of the boilers scattered live coals about the room. Waste about an oil tank caught fire and an explosion followed. The boiler and engine room was almost totally destroyed and the generators were badly damaged by heat and water. The plant was installed by the Westinghouse company, and had but recently been turned over to the company by them. The fire tied up the Akron city lines and the Akron, Bedford & Cleveland Electric Railway until power could be secured from the Cuyahoga Falls power house.

The Street Car Float Idea Spreading

The street car float idea seems to have taken hold of the managers in the West. Since the inauguration of this idea during the Mardi Gras celebration in New Orleans there has been considerable talk by the Western managers of making this a feature of carnivals, etc., and since that time the float idea has been used to advantage in Milwaukee. Now it is announced that Wichita is planning to surprise its citizens by utilizing the floats in a coming festival in that city, and that President McGowan, of the Indianapolis Street Railway Company, is arranging to make the floats an important feature of the carnival in that city in October. As the ideas of the Wichita and Indianapolis managements are not known in regard to the design and subjects of their floats, it is probable that we may see some radical changes in both design and subjects.

Chicago Street Railway Questions Likely to be Submitted to the People

It is reported from Chicago that the street railway questions now being considered by the Street Railway Commission will be submitted to the people by an informal referendum if a satisfactory method of reaching the public can be devised. One proposed method of securing the suggestions of the people is to ask citizens to appear before the commission with their opinions. For this purpose a number of representative men will be asked, as the traction companies have been asked, to submit statements of their views for the consideration of the commission. To reach the people more directly and to submit propositions which affect them it is proposed that circulars be used. The questions of municipal ownership, long term franchises, and the terms which should be demanded in granting them, can be stated and opportunity for a statement of opinions given. The expressions thus secured will be formulated as a statement of public opinion.

Disappointments in City Census Returns

The citizens of Washington, Cincinnati and Buffalo, of which official returns as to their population have been made by the census officials, are greatly disappointed at the showing made by their respective cities. From all accounts, the citizens of Washington are deepest in their gloom, and the estimates of the local authorities on such subjects have been shattered. All sorts of estimates had been made regarding the wonderful growth of the city, but they were all destroyed by the official returns, which show no perceptible gain. How is this accounted for? This is the question they have asked themselves, and, after careful consideration, have laid the responsibility at the door of the electric railway, which has worked so many other wonders since the compilation of the last census. The suburban development stimulated by the wide and rapid extension of the electric railway is held accountable for the results. The increase in Cincinnati has been but 9.77 per cent for the ten-year period, and at Buffalo only 37.77 per cent for the same period, as against 64.8 for the period of 1880-1890. These are the first returns of the census officers, and as subsequent reports are made the estimates of population in other cities are liable to receive a serious shock. The electric railways have built up that portion of the country surrounding the cities which in the times of the horse car were inaccessible because of that slow mode of locomotion, and yet were not quite distant enough to build up a steam railroad traffic. In all, it has filled a long-felt want, and the latest reports show that it has even exceeded the expectations of its early champions, who predicted relief for the congested city districts on its advent.

Electricity on the Manhattan Elevated Railroad

General Superintendent W. E. Baker, of the Manhattan Elevated Railroad Company, of New York, has announced that the electrical equipment of the company's lines will be completed by Oct. 1, and that at least one trial train will be operated over its Second Avenue line by that date. The company's new power plant will not be sufficiently advanced to furnish power at so early a date, but the Metropolitan Street Railway Company will supply power temporarily from its new plant at Seventy-Fifth Street and the East River. The new electric trains will consist of six cars, instead of five, as at present, and will run on one-minute headway. They will consist of two motor cars, one front and one rear, and four regular passenger cars. The one additional car will permit of the handling of a considerable number of passengers, and will be especially useful in rush hours. The plans for the electrical equipment also call for the substitution of the gas lighting system now in use on the cars and in the stations with electric lights and the installation of a telephone system connecting all stations. Contracts are now being let for the installation of these systems. The motor cars will each be equipped with four 100-hp motors, thus giving a total of 800 hp to each train.

Collecting Fares on the Brooklyn Rapid Transit

The Brooklyn Rapid Transit Company has ordered that its conductors ring up the fare immediately after the passenger boards the car. This system has long been in use on the Coney Island & Brooklyn Railroad, and its adoption by the larger company is largely due to the apparent success there observed. W. W. Wheatley, general superintendent of the Brooklyn Rapid Transit, states that the new arrangement is not made as an experiment, but that after careful investigation the management has decided that without imposing unreasonable annoyance on the conductor it has a decided tendency toward preventing the "skipping" of fares, and for this reason it has been permanently adopted. Mr. Wheatley asserts that the conductors themselves, especially the older men, appreciate the advantages of the system, and are perfectly satisfied with the change. This is probably partly due to the peculiar sense of honesty with which such a large portion of the traveling public is affected. Many passengers who would attempt to ride free if they thought the railway company only would suffer and do not realize the severity with which "skipping" is looked upon, would condemn as the grossest meanness the cheating of a conductor out of a fare. Another advantage of the system is that dishonest conductors cannot fall back on the excuse of not having collected the fares when questioned by an inspector regarding discrepancies in the number of passengers and the register indications. In case a person boards the wrong car the conductor merely makes a note to that effect on the back of his day card, and is thus relieved of all responsibility. By the adoption of this system the former use of double registers has been necessarily discarded, cash fares and transfers being rung up on the same register.

Plans for a Chicago Subway

On July 25 President John M. Roach, of the Union Traction Company, of Chicago, presented the Street Railway Commission with detailed plans for the construction of a downtown subway system in Chicago. The cost of constructing the proposed subway is estimated at $25,000,000. In drawing the plans for the new tunnel careful consideration was made of the underground systems of London, Boston, Buda-Pest and the plans for the New York tunnel. The plan in general provides for the construction of six distinct loops diverging from a transfer point beneath the heart of the city, and include the construction of about 10 miles of underground road.

The following are the routes as proposed:

Dearborn Street Subway—Enter river tunnel at Michigan Street, to Madison Street, to State Street, to Randolph Street, to Dearborn Street.

LaSalle Street Subway—Enter river tunnel at Michigan Street, to Madison Street to Dearborn Street, to Randolph Street, to LaSalle Street.

Washington Street Subway—Enter river tunnel as at present, to Franklin Street, to Monroe Street, to Dearborn Street, to Madison Street, to Franklin Street, to Washington Street.

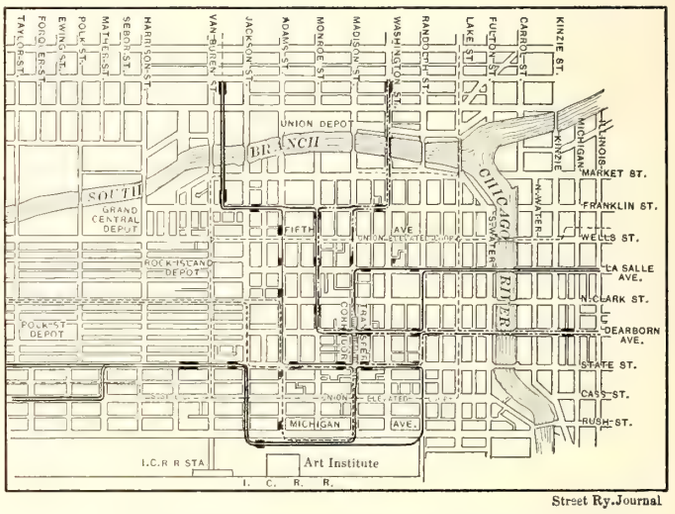
Van Buren Street Subway—Enter river tunnel as at present, to Franklin Street, to Adams Street, to State Street, to Madison Street, to Dearborn Street, to Monroe Street, to Franklin Street, to Van Buren Street.

Clark Street Subway—Enter at Twelfth Street, to Jackson Street, to State Street, to Adams Street, to Michigan Street, to Madison Street, to Dearborn Street, to Adams Street, to Clark Street.

State Street Subway—Enter at Twelfth Street (Wabash Avenue at Hubbard Court), to Jackson Street, to Michigan Street, to Randolph Street, to State Street, to Madison Street, to Michigan Street, to Jackson Street, to State Street.

The plan provides for the issuance of transfers at a station to be located under Madison Street, between Dearborn and State Streets. All loops are to touch this transfer corridor and thus permit of a ready change of cars by passengers.

According to the specifications, the bottom of the tunnel is 32 ft. below the street level. Underground work is provided for, sewer work and gas mains being placed above, instead of below, the



GENERAL PLAN OF CHICAGO SUBWAY

transportation tunnel to prevent the escape of gases into the tunnel proper and lessen the danger in case of explosions.

The tunnel is to be 32 ft. wide and 14 ft. high, separated into two compartments for an up and a down track by a wall of masonry. The tracks are 30 ft. below street level, while the platforms are constructed about 15 ins. higher. Sewage, which in Chicago has proved an obstacle to all subway plans, is cared for by iron pipes on either side of the street, as well as one deeper system below the tunnel proper. Mr. Roach believes the upper sewers will drain surface water from the streets, while the smaller one below will furnish drainage for other wastes.

Between the top of the subway and the street level are conduits for telephone and telegraph wires, electric light cables, all city wires and pneumatic tubes. Compartments 6½ ft. deep and 5½ ft. wide are provided. President Roach has this to say of the plans:

"The plans were drawn hastily and without a study of details, such as I should desire. They embody features that seem to me desirable, and can be used to advantage by the commission. The street railway companies are not ready to make a proposition for the construction of any such system. The Chicago City Railway Company has not worked in the preparation of these plans, and it is likely some outside corporation would like to secure the right."

Special Meeting of the Massachusetts Electric Companies

At a special meeting of the stockholders of the Massachusetts Electric Companies held July 30 it was voted as follows:

"To amend the declaration of trust by changing the dates for the payment of semi-annual dividends of the preferred shares from the first days of June and December to the first days of January and July of each year.

"To approve the purchase of the stock of the Lowell & Suburban (12,000 shares) on the basis of two shares of preferred and one and one-half shares of common stock of the Massachusetts Electric Companies for each share of Lowell & Suburban stock.

"To approve the purchase of the stock of the South Shore & Boston (6900 shares) on the basis of one share of preferred and three-quarters share of common stock of the Massachusetts Electric Companies for each share of South Shore & Boston stock."

At the meeting President Gordon Abbott said in part: "The first fiscal year ends Sept. 30, and before the annual meeting on

Nov. 7 a full report of the year's operations will be sent to all the shareholders; meantime a few figures as of June 30 last may be of interest. When on that date a year ago the trustees organized they received either all or a controlling interest in the shares of thirty-one corporations, two of which were lighting companies. Since then four other companies have been acquired, including the South Shore & Boston and the Lowell & Suburban, whose acquisition you are asked to-day to approve."

He then referred to the consolidation into system of the various roads controlled by the company, and continuing said: "The results of the operation of the companies in which you are interested, excluding as before the Lowell & Suburban and the South Shore & Boston and also the New Bedford, Middleboro & Brockton, which company had not been acquired by the trustees at this time last year, are as follows, comparisons being made with the same period of the fiscal year, 1899:

	1900	1899	Increase	
Gross earnings.....	$3,102,518	$2,809,464	$293,053	10.4%
Operating expenses..	2,132,679	2,087,898	44,781	2.14%

Operating ratio 68.75%.

"For the same period of nine months the net divisible income, after deducting all interest and other charges, has increased by $207,893. These figures do not fully represent in the improvement in the net divisible income, for the following reason: Believing it wise to provide a general fund as an insurance against losses caused by accidents to persons, the companies in which you are interested mutually established such a fund at the beginning of the present fiscal year, and each company now makes quarterly payments of a percentage of its gross earnings. The balance to the credit of this fund on June 30 was $117,000. Inasmuch as damage cases are seldom settled until some months after the accident occurs and inasmuch as only those accidents which happened since the first of last October are properly chargeable to this fund, the companies have been paying a double charge during the last nine months, because while they have been making the payments to the new fund they have been at the same time obliged to settle a number of claims antedating the establishment of that fund; therefore, in making a strict comparison of the results it would be proper to add the balance of this accident fund to the increase in net divisible income, making the total increase $324,893."

The Utilization of Water Power for the Electric Railway System of Minneapolis and St. Paul *

BY EDWARD P. BURCH, CONSULTING ELECTRICAL ENGINEER

It is well known that within a few years a new dam has been constructed in this city across the Mississippi River just below St. Anthony Falls, that electricity has been generated by the power produced at the dam, and that the power has been utilized for the electric railway system of Minneapolis and St. Paul. It is the purpose of the lecture to review the engineering which has recently been accomplished in the utilization of this power.

THE MISSISSIPPI RIVER

The source of power is the upper Mississippi River, a peculiar stream; generally quiet and governable, yet at times of flood apparently beyond control. The flowage characteristics have been averaged year after year until we are certain of the general nature of the annual changes. By providing liberal margins we can predict with fair accuracy the amount of water which can be depended upon. These characteristics are given in Fig. 1, which shows the months of the year along the base line and the flowage in cubic feet per second vertically.

The flowage changes materially during the different seasons. During the first months of the year the lakes and great swamps in the northern part of our State freeze so solid that the flowage is greatly diminished. As warm weather comes on in April, the melting ice and snow invariably produces a flood, so that within a week of a spring break-up the volume may increase ten-fold. The summer flowage is several times greater than the winter flowage. There is commonly a second flood in September, after which the amount of water gradually decreases as cold weather comes on.

These characteristics of flowage are changing quite materially. The United States Government is constructing permanent dams at the outlets of the great swampy lakes on the upper Mississippi, thus forming immense reservoirs. The object of these reservoirs is to collect surplus water, principally in the spring and fall, which may be systematically released, especially in case of drought in midsummer or late in the fall. This storage capacity may ultimately become 100,000,000,000 cu. ft.

* Paper read before the Northwestern Railway Club, April 10.

Not only is the intensity of the spring and fall floods thus reduced, but navigation is facilitated and a more equitable distribution of water for power results. As this immense reservoir system grows, the curves of flowage become more nearly flat. At present the general mean minimum flowage in February is about

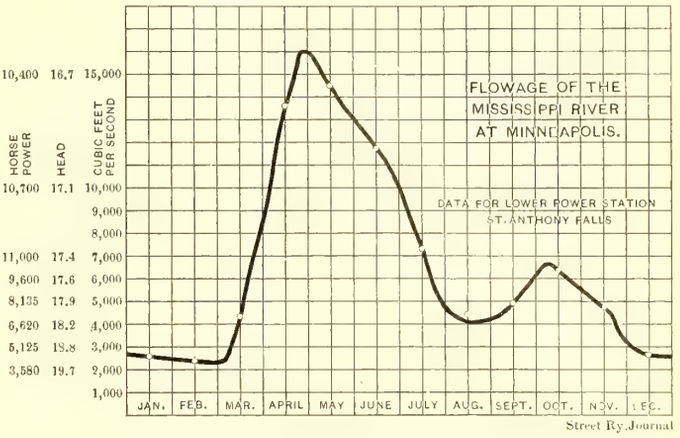


FIG. 1.—FLOWAGE OF RIVER AT MINNEAPOLIS

2500 cu. ft. per second, the spring flood commonly reaches 15,000 cu. ft. per second, and the summer flowage at least 6000 cu. ft. per second. By utilizing local storage the amount of power available may be increased 10 per cent at times of heavy demand.

ST. ANTHONY FALLS

Within the limits of the Twin Cities the Mississippi has a fall of over 110 ft. Just above the city limits there is what is known as Coon Rapids, where there is a fall of 20 ft. This power has not been developed. Between the Minneapolis Western Railroad bridge at Eleventh Avenue South in Minneapolis, and Fort Snelling bridge in St. Paul, there is a fall of 40 ft., along which the government has laid out and is now constructing locks and dams.

The main St. Anthony Falls, with a fall of 50 ft., have been utilized for forty years. With normal summer flowage, 6000 cu. ft. per second, about 25,000 mechanical hp are available and are used, largely for flour manufacturing.

CONSTRUCTION OF THE NEW DAM

St. Anthony Rapids, just below the main falls, has been developed within the last few years. The construction of a dam below what was formerly known as the "rapids" (now known as the lower power) had been in the minds of capitalists and engineers for many years. With normal summer flowage it was estimated that a dam giving a 20-ft. fall could develop 10,000 hp.

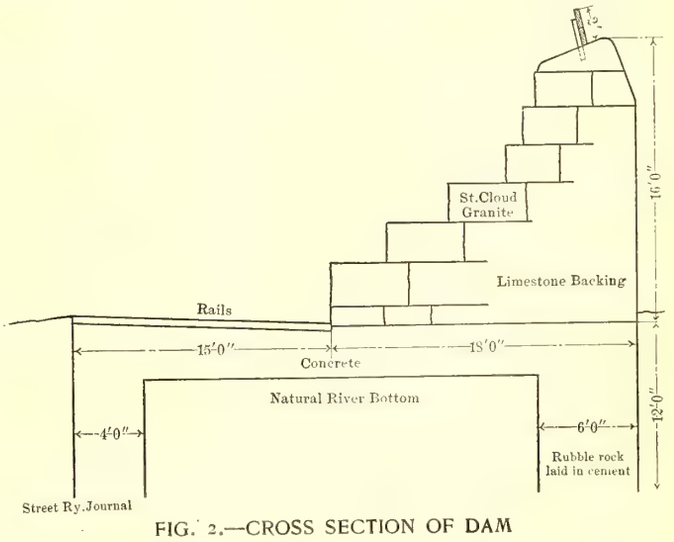

FIG. 2.—CROSS SECTION OF DAM

The riparian owners, St. Anthony Falls Water Power Company, having procured ample English capital, their hydraulic engineer, William de la Barre, started the construction of this new Lower Dam at St. Anthony Falls in May, 1895. The work was finished and turned over to an operating company Jan. 1, 1898. Fig. 2 shows a map of the upper and lower power at St. Anthony Falls.

In the construction of the lower power the general plan carried out was to build a dam directly across about two-thirds of the main river, then making an obtuse angle, run diagonally across toward the east bank to a power station at the foot of the canal or

head race thus formed. This plan of construction was a most advantageous one. The walls of the canal were built first, and on the dry east bank the great waste gates were installed and the power station foundations were completed, all during the first season.

The second year, 1896, the water of the entire river was de-

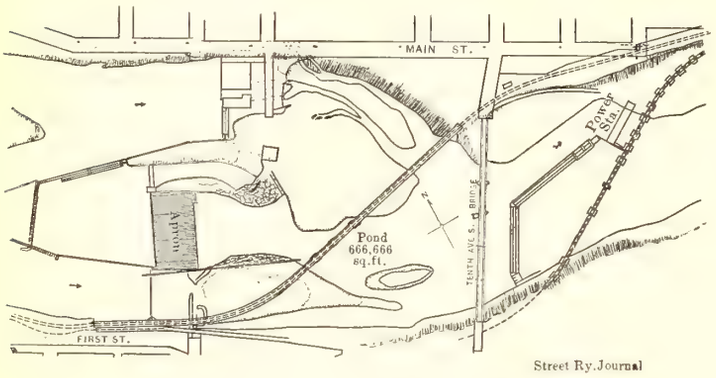

FIG. 3.—MAP OF UPPER AND LOWER DAM

flected from its old bed into the new canal and sent through the waste gates and also under the power station. A coffer-dam was then built across the old bed of the river. The main dam, located 2000 ft. below the upper falls was then started, and was nearly completed during the second year. At the beginning of the third year, the spring of 1897, a most disastrous flood, amounting to 60,000 cu. ft. per second, swept away the coping and other portions of this section. In repairing this break, a rock-filled, timber-framed approach, lined with steel plate was built in front of this section of the main dam, in order to ease the battering which piers, logs and ice give the structure.

Examining the plan as a whole, note that the great length of the dam allows the water to fall over a very long crest of the dam during a flood, thus lessening the wear and tear of the fall by distributing it over a greater surface. A cross-section of the main dam is shown in Fig. 3.

The dams are 1085 ft. long. The height of the dams is from

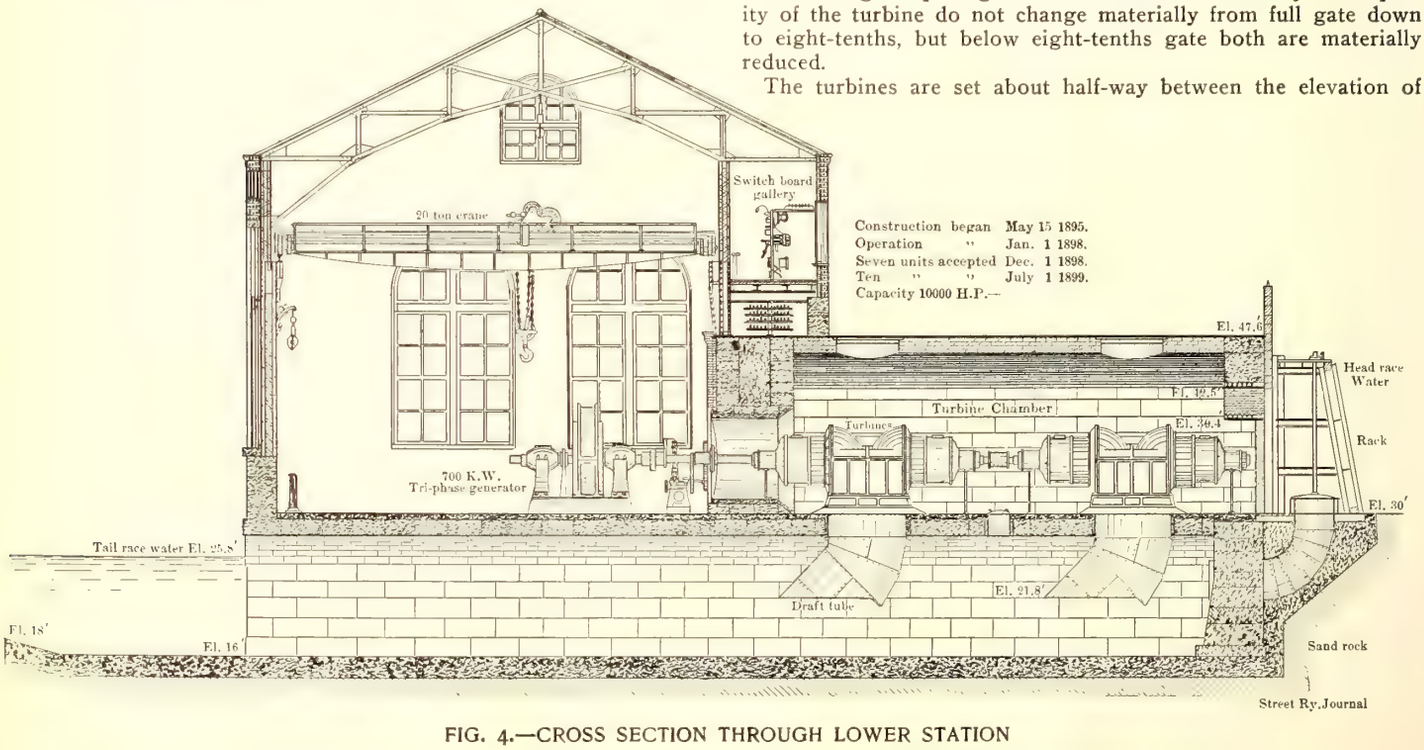

FIG. 4.—CROSS SECTION THROUGH LOWER STATION

14 ft. to 16 ft. above the river bed. Below the superstructure there is a 3-ft. base of concrete, 33 ft. wide. This base is especially well reinforced by a rubble rock and concrete dyke construction in the sand rock below the crest line of the dam and again at the toe of the dam. This will prevent undermining. The face of the dam is perpendicular. The down-stream side is so shaped or sloped as to ease the momentum of the water and discharge it horizontally, thus preventing an undertow which might prove fatal to the structure.

The main structure is of limestone from the quarries on the east bank of the river. The facings are of St. Cloud granite. The coping is lined with skeleton steel plate and the base of the dam with steel rails in 15-ft. lengths laid side by side in cement. These rails are laid with their outer ends 6 ins. higher than the end next to the dam—thus a pool of water is formed which acts as a cushion and protects the concrete work from erosion.

THE STATION

The power station forms 200 ft. of the dam. Inside, it is one large room 250 ft. long, from 45 ft. to 55 ft. wide, and 50 ft. high inside. The station is heated by electric heaters; a 20-ton traveling crane is provided.

The station, shown in section, Fig. 4, is built on solid sand rock. First, a concrete base, the present tail-race floor and foundation for tail-race arches, was laid 2 ft. thick under the power station. The top of ten tail-race arches forms the floor or substructure of the station. The turbine chambers and the tail-race arches are spaced horizontally 20 ft. apart from center to center. Large sulice gates allow a by-pass for the water in front of the chambers to the race below. In front of the entrance to the turbine chambers, a structural steel framework is formed to support the racks—a steel screen of ¼ in. iron, 3½ ins. wide and spaced 1 1-3 ins. apart, to prevent the entrance of floating logs, bark and ice.

THE TURBINES

In the water chambers ten large turbine units were installed. The capacity of each unit is approximately 1150 hp on 20-ft. acting head at 130 r. p. m. The capacity of the turbines varies as the square root of the cube of the acting head. There is one speed on any given head at which they run at highest economy, this speed varying with the square root of the head. Thus, on 17½-ft. head the horse power would be

$$1150 \times \sqrt{\left(\frac{17.5}{20.0}\right)^3} \text{ or } 940,$$

and the most economical speed 121.6. If a higher or lower speed is used on 17½-ft. head, the horse power capacity of the turbine is materially less. At 190 r. p. m. the horse power capacity is naught.

The object of the turbine governor is to provide a speed of 130 revolutions, given any head and any load which may be on the generator. This is done by a centrifugal governor which controls the turbine gate opening or water inlet. The efficiency and capacity of the turbine do not change materially from full gate down to eight-tenths, but below eight-tenths gate both are materially reduced.

The turbines are set about half-way between the elevation of water in the head and tail-race. The pressure above the turbine runner and the suction from the draught tubes together form the head on the turbine. Should the normal elevation of water in the head race increase 2 ft. during a common spring or fall flood the normal elevation of water in the tail-race would make a corresponding increase in elevation of 5 ft., or even above the floor of the power station should the flowage amount to 30,000 cu. ft. per second. The result is that during a flood there is a smaller quantity of water per turbine and a much lower acting head. Therefore, the capacity of each unit and of the power station is

always the least when the quantity of water in the river is greatest and vice versa. Floods as well as droughts are thus undesirable.

The acting head on the turbines is nearly 1 ft. less than the fall of water produced by the dam. This is due to friction losses

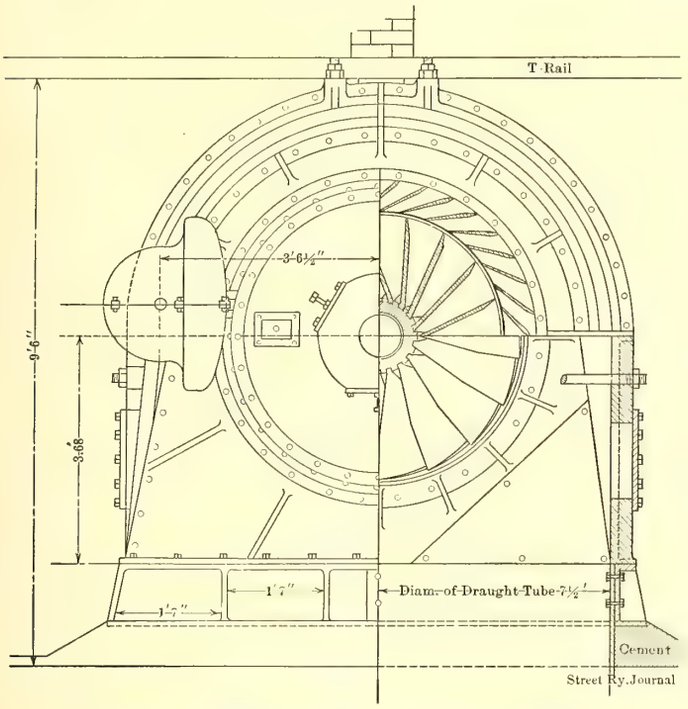

FIG. 5.—CROSS SECTION OF 46-IN. TURBINE

past booms, through racks, eddies in the turbine chamber, and the piling up of the water discharged by the draft tubes.

Drawings of the turbines are given in Figs. 5, 6 and 7.

Each 1150-hp turbine is directly connected to a 1000-hp electric generator, the turbine shaft passing through a water-tight flume cover into the generating room. Ten 1000-hp and two 150-hp

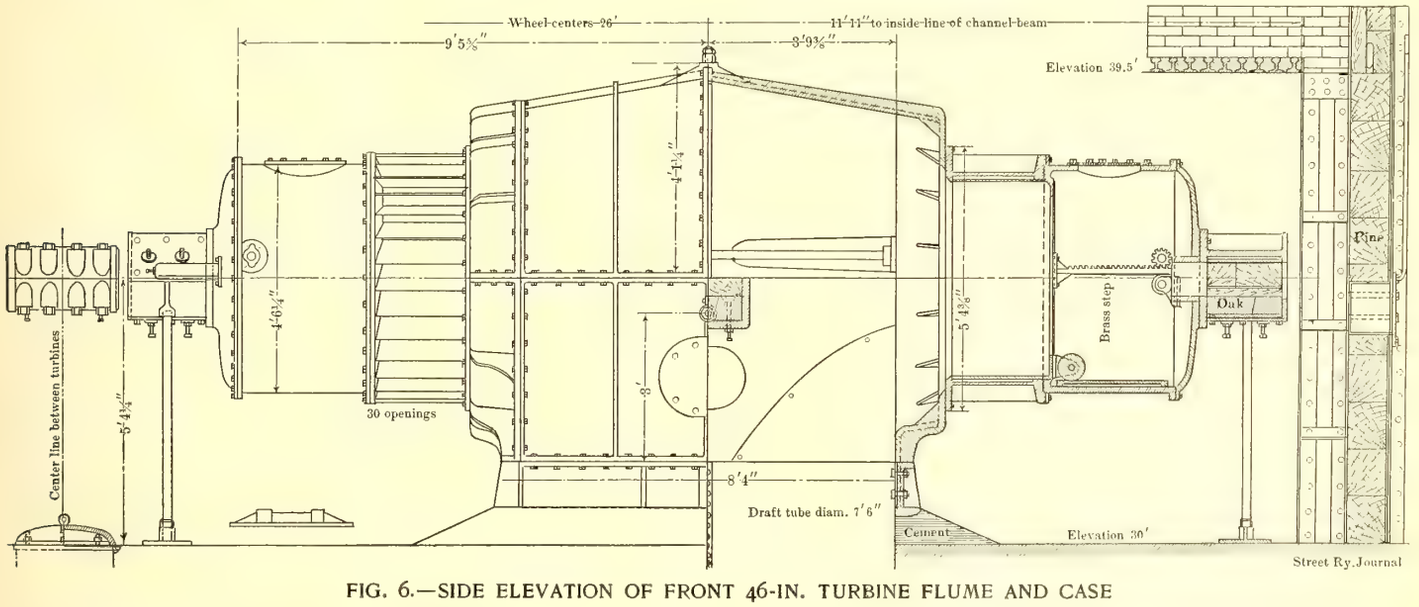

FIG. 6.—SIDE ELEVATION OF FRONT 46-IN. TURBINE FLUME AND CASE

generators have been installed. The generators are of two classes or types, well adapted to the work of distribution to be referred to later. The power, after being converted into electricity, is sent to the switchboard in the gallery, where it may be controlled and distributed.†

THE TWIN CITY RAPID TRANSIT COMPANY'S ELECTRIC RAILWAY SYSTEM

The power service is now ready. One of the corporations to whom propositions were sent on the sale of the power, was the Twin City Rapid Transit Company. This company has an electric railway franchise, owns and operates the entire electric railway system of Minneapolis and St. Paul. It has 240 miles of track in service. Its annual revenue is over $2,500,000, coming nickel by nickel from 50,000,000 passengers. Its annual car mileage is 13,000,000. The maximum number of cars in ordinary daily service is about 400; in maximum service, 550.

From 1891 to 1897 it had four steam plants with a capacity of 11,500 hp, equipped with modern boilers and engines and fairly modern generators. These plants were distributed as shown.

By a consolidation into one large power station, many savings due to the cheap water power, decreased labor, repair expenses and distribution losses were apparent.

A forty-year lease of all the power produced by the dam was effected by the railway company about Jan. 1, 1897. The choice of generating machinery, transmission and distribution plans and equipment was left to the railway company.

TRANSMISSION AND DISTRIBUTION

Without detailing the investigations made by the company, we can say briefly that exhaustive study was made of the most modern electric plants in the country, of most improved methods of transmitting and distributing large blocks of power over long distances.

Given 10,000 hp at the dam, the problem was to convert this power into electrical energy and distribute it to 500 cars scattered over two cities. About sixty of the heavier cars were within a mile of the station. The generation and transmission of 2000 hp for these sixty cars was planned and carried out by using low voltage direct current. This low voltage, 600 volts, is adapted only for short transmissions. It was necessary to send 3000 hp to No. 1 steam station, now known as a sub-station. The distance from the water power station to this sub-station is 1½ miles. For this transmission it was necessary to employ alternating currents and to use a pressure six times as high as that used for the short and ordinary transmission just referred to.

Similarly, 100 hp is sent to No. 2 steam station, now a sub-station. For St. Paul 2000 hp was sent to No. 3 sub-station, formerly the old steam plant, and 2000 to sub-station No. 4, a building and location especially selected for the purpose.

Alternating current apparatus is necessary for economical and structural reasons when we will transmit large blocks of power over long distances. High pressures are necessary in order to reduce the first cost of apparatus and in order to decrease transmission losses.

If you were going to transmit a million gallons of water 1 mile per day, a small-sized pipe and moderate pressure, 60 lbs. per square inch, would be used. If you were to transmit a greater quantity of water and several miles, you *could* increase the size of the main, reducing the friction loss materially. A better plan, however, one involving less first cost, might be to use the small pipe and raise the pressure to, say 1200 lbs., as oil is transmitted in Ohio.

Similarly, in transmitting large blocks of electric power over long distances, good engineering calls for small conductors and high pressure.

The two transmissions to St. Paul were especially long, 7 and 9 miles. It was necessary to use 12,000 volts, an extraordinarily high pressure, in order that the cost of cables and the losses in transmission might be reduced. Twelve thousand volts was the highest pressure heretofore carried for heavy power distribution

† Additional notes on station and other equipments will be found in *American Electrician*, May, 1898; *Street Railway Review*, February, 1899; STREET RAILWAY JOURNAL, June, 1897; *The Electrical World*, Oct. 8, 1898.

in underground cables, and many were the prophecies of failure. One cable, 2 ins. in diameter, was used for each 2000 hp transmitted. Each cable contains three wires, each .4 in. in diameter, separated and insulated from each other and from a lead sheath by common manilla paper impregnated with resin oil, linseed oil and other insulating compounds. The cable is drawn in cement conduit

An attendant is required to supervise the transforming and converting apparatus at the sub-station and to care for the low tension railway distributing switchboards. Copper feeders distribute the power from these switchboards to the different trolley sections. Over 1,200,000 lbs. of copper are required for these local distributions. The current at the car is under the control of the

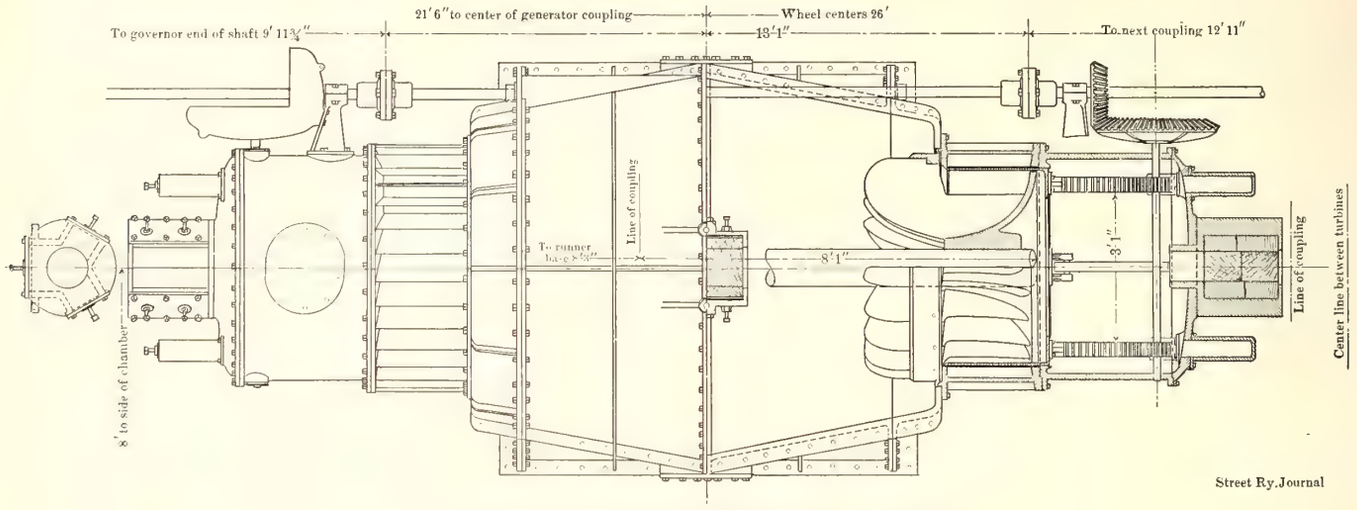

FIG. 7.—REAR 46-IN. TURBINE FLUME AND CASE

ducts 3 ins. in diameter. These ducts are protected by concrete and are laid about 3 ft. below the roadbed. Manholes are located every 500 ft. for the purpose of drawing the cables in the duct, making cable splices and for inspection and repairs. Drawings of cables and splices are reproduced in Fig. 8.

SUMMARY

Reviewing the complete cycle, let us start over again with the water which formerly tumbled down the rapids below St. Anthony Falls. It has been dammed, a pond formed and a fall of 18 ft. produced. The falling water, in passing through the turbines, develops 10,000 hp, which is converted into electric power by the generator attached to the turbine. Direct current of low pressure is provided by two of the 1000-hp generators, while alternating current of moderately high pressure is generated by the remaining eight generators. All the electric power is first carried to a switchboard in the gallery. The operating electrician can start the generation of current, vary the amount, and read from the meters the amount developed. By means of switches, varying amounts are sent to the different sub-stations to meet the changing conditions of load and service. The low voltage direct currents are sent to the nearer lines, especially for the heavy interurban service. Medium pressure alternating currents, at 3500 volts, are sent to the Minneapolis sub-stations, and the extremely high pressures, 12,000 volts, are sent to the St. Paul sub-stations.

It may be interesting to state that the transmission of 2000 hp over 9 miles to the further St. Paul sub-station, at 12,000 volts pressure, is accomplished with a cable loss of but 5 per cent of the power so transmitted.

FIG. 8.—CABLE SPLICE FOR THREE-PHASE 1200-VOLT CABLE

At the sub-station the alternating current is reduced in pressure and converted into direct current, after which the sub-station operator sends the power through his local distributing switchboard.

motorman, who uses it for the motors on the trucks beneath the cars.

In this railway system there are three interurban lines; the longest, 22 miles long, between St. Paul and Stillwater, has on the car equipment air brakes, air whistles and arc-lamp head lights. It makes 44 miles per hour, maximum speed; has a schedule of 22 miles per hour. Each car has a telephone used for dispatching cars. Long 10 per cent grades are mounted. All interurban cars are double truck, 44 ft. long, weigh from 18 to 22 tons, and seat fifty-two passengers.

The efficiency of the whole power system is very low. There is a 5 per cent loss due to booms, racks, eddies, etc., near the station, so that we may say the efficiency of the falls is 95 per cent.

	Maximum per cent	Ordinarily per cent
The efficiency of the turbines	80	78
The efficiency of the generators	95	94
The efficiency of the station distribution	92	90
The efficiency of the conversion to direct current	94	91
The efficiency of the local distribution	90	92
The efficiency of the railway motors	80	70

So that of the 10,000 hp developed by the turbines, the railway motors could not get 5900 mechanical horse-power at highest efficiency and not over 5000 hp during ordinary operation. Moreover, 50 per cent of all the power delivered to the motors is spent in acceleration, only to be destroyed in the same block by braking. The motor tractive effort is very high, 25 lbs. per ton, compared with 5 lbs. per ton in steam railroad service.

The cost of the entire power service on this system is but 14 per cent of the total cost of operation of the system.

In closing the lecture, let us consider for a minute the application of an entirely similar system for *steam* railroad service.

The amount of the steam railroad business in this country is not large. The Twin City Rapid Transit Company's passenger service was $2,500,000 last year, while the entire steam passenger service of the country during 1899 is given by one authority as $330,000,000. A far greater problem for the engineer's consideration is the freight business, amounting to $880,000,000 per annum.

The power might be generated by steam or gas engines if water power was not available, but the general plan of the station, the polyphase generators, the transmission, the sub-station and utilization could be quite similar to the system above described.

Many of the steam railroad systems in and radiating from the Twin Cities present quite favorable conditions for the substitution of electricity for steam. This is particularly true where the public appreciates and will use better transportation facilities. By better, we mean faster service, lower fares and more frequent train service. Where these conditions can be worked out, the motive power can be changed from steam to electricity with a resultant decrease in operating expense per passenger carried.

The heavy service on lines in thickly settled districts and between our cities and towns will adopt electricity first, after which the main trunk lines, with their light passenger service, and later

the heavy freight trains will follow, when the management finds electric service is satisfactory as a motive power and in financial results.

The first few years of the coming century will see rapid progress along these lines. Some of the members of the Railway Club will be found engaged in this development.

DISCUSSION

Prof. G. D. Shepardson—Mr. President, there are about three points that I could speak of in which the Twin City Rapid Transit Company has been one of the pioneers.

One is the general adoption of electricity for power. I believe that when the horse cars were finally dropped in the Twin Cities this was the largest electric street railway system in the world. Since that time some of the Eastern cities have exceeded these cities in the number of cars and number of miles of track. This system also I believe is one of the first of the interurban roads, that is, in connecting neighboring cities. Nowadays it is nothing at all uncommon to find electric railway lines connecting neighboring cities. I think at present the longest continuous line in operation is one between Detroit and Ann Arbor, Mich., where there are 40 miles in one stretch. But at the time the interurban road was put in between Minneapolis and St. Paul I believe that was the longest electric railway line in the world.

The other point in which the Twin City Rapid Transit Company has been a pioneer is in the transmission of power at a high pressure for a considerable distance under ground. The speaker of the evening mentioned to-night the difficulties which were expected to arise, but I believe this is the first case where energy has been transmitted so long a distance, at such a high pressure, under ground.

It is a point of considerable interest to know that the telephone people were terribly disturbed lest the high pressure alternating current which was being sent under ground should be a disturbing factor on their telephone lines. This was the only place in the country where they could examine the matter, and the telephone engineers came here from Boston, New York and other Eastern places to examine the system.

So, in at least three particulars, the Twin City Rapid Transit Company has been a pioneer.

I suppose I might add a fourth way, which is not, perhaps, so favorable to railway people, and that is that the vigorous competition between the trolley roads and the steam roads had its effect, and the short line trains were gradually abandoned. That experience has been duplicated in other places since, but I believe that this is the first place where the trolley cars successfully competed with the short line steam roads.

It is interesting to notice that the steam railroad people have adopted the very means which have taken from them a great deal of business, and in quite a number of cases the steam roads have adopted the practice of trolley service on their short lines, with a marked diminution in running expenses and a marked increase in profits. As the speaker said, when we increase the frequency of the service we increase the amount of travel.

The Twin City Rapid Transit Company has been one of the pioneers in other improvements than those already mentioned. About the first instance where street railway feed wires were placed under ground was on Nicollet and First Avenue South in Minneapolis. The "jumper system" of connecting the different sections of the conductors by means of fuses around the circuit breakers was worked out in Minneapolis, the idea having been proposed, I believe, by Mr. Burch; this plan has since been adopted by many large roads, since it reduces the fluctuations of load on the individual feeders as well as upon the power house; it maintains a better pressure upon the lines and thus enables a higher speed to be secured; it reduces trouble at the switchboard and at the power house as a result of the less fluctuation of current, and it is of especial value in case of congested traffic at unusual points. The series-parallel controller, in universal use at present, is the result of the experience of many roads and many men, and it is a matter of some pride that two members of this club, Mr. Burch and Mr. F. W. Springer, of the University of Minnesota, are entitled to the credit for designing the controller which has been in use for a number of years on the Twin City lines and which was practically the first one that proved to be a really successful device; this effected a saving of fully 20 per cent of the power formerly required for operating the cars. I may be pardoned for mentioning in this connection that I had the honor of being the first to discover the true explanation of the curious phenomenon known as "bucking," in which a car suddenly and violently stops as if by a collision; this had been previously considered as a mysterious visitation of Providence that was inexplicable except in a very few cases; by careful examination of a number of cases occurring in this State, the speaker finally located the invariable conditions which caused the trouble and was able to demonstrate a method for making such accident impossible. The safety gates, now so common, were first applied to street cars in Minneapolis, although somewhat similar to those on the elevated roads.

Secretary Foque—Mr. Burch spoke of the generator shaft being extended 2 ft. beyond the bearings, the idea being to eventually put on a vertical direct-connected engine. Is that in case of the failure of the water power?

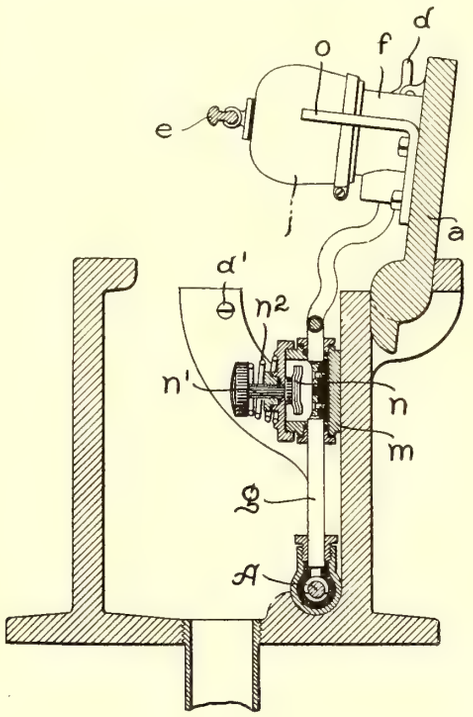
Mr. Burch—When the electric railway traffic and load grow beyond the capacity of the river in winter, reserve engine capacity is needed. The original plan was to have this equipment at the station. It is not probable that this plan for reserve or for additional capacity will be carried out in this way.

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED JULY 31, 1900

654,586. Conduit Electric System; F. M. Ashley, New York, N. Y. App. filed Feb. 26, 1898. The invention in general consists of a conduit provided with a removable plate to which the main portions of the working mechanism inside of the conduit are attached. The construction is also such that when the cover



PATENT NO. 654,586

is removed the circuit between the main and sectional conductor is open.

654,868. Electric Railway; G. A. Lyncker, Munich, Germany. App. filed April 23, 1900. This is a sectional conductor system in which the magnets which close the branches between the main conductor and the sections are energized by a battery carried on the car.

654,670. Snow Plow; M. Perreault, St. Thomas de Joliette, Canada. App. filed April 7, 1900. This plow is adapted to lift the snow from the track, divide the mass of snow in two parts and separately discharge the divided mass on opposite sides of the track. The invention relates particularly to the construction of the framework and to the devices for raising and lowering the edge of the plow.

654,803. Trolley Wheel; S. G. Reynolds, Easton, Pa. App. filed Dec. 11, 1899. The wheel consists of a center cored out to receive a felt packing, and removable side discs, the center and discs having interlocking parts and the whole provided with an axial pin adapted to be locked by means of cotters, or otherwise within the jaws of the fork at the upper end of the trolley pole.

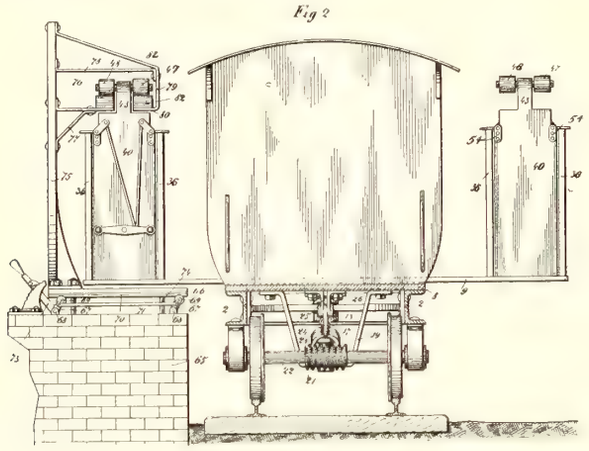
654,805, 654,806, 654,807, 654,808, 654,809. Automatic Brake Shoe or Block; W. H. Sauvage, Denver, Col. Apps. filed Oct. 30. 1899, and Nov. 13, 1899. These inventions are all modifications of the one idea of utilizing the rotary movement of the wheel to apply the brake, the invention consisting specifically of the details of construction of the brake shoe and the rigging.

654,820. Railway Cross Tie; W. M. Woodworth, Sycamore,

Ind. App. filed Feb. 20, 1900. The tie consists of a flat plate having wooden blocks strapped to it, upon which the rails rest.

654,825. Device for Transporting Passengers from and Onto Moving Cars; E. F. Böttcher, Lengenfeld, Germany. App. filed June 10, 1898. The car carries a rotary platform on which rests a number of small cabs. A person or persons desiring to leave the car at a station will step into one of the cabs, whereupon the platform is rotated to swing the cab into line with a receiving rigging built on the station platform. This rigging lifts the cab from the platform while the car is in motion.

Fig 2.



PATENT NO. 654,825

654,854. Car Fender; G. D. Smith, Paterson, N. J. App. filed March 30, 1900. The net is supported in such a way that a body falling into it will cause it to assume a basket shape to retain the body and prevent its rebounding.

PERSONAL MENTION

MR. JOHN SCULLIN, the St. Louis street railway magnate, has just been elected president of the Wetmore Tobacco Company, to succeed Mr. Moses C. Wetmore.

MR. E. S. REILLY, manager of the West End Traction Company, of Pittsburgh, has started for Europe, where he intends to sojourn for about two weeks. Mr. Reilly intends to visit the Paris Exposition.

MR. E. C. FOSTER has not been appointed general manager of the Massachusetts Electric Companies, as reported in the STREET RAILWAY JOURNAL for July 28, but has had his duties increased so that he is now manager of the individual companies controlled by the Massachusetts Electric Companies.

MR. GEORGE L. COOKE, who has been in charge of the Interstate Consolidated Street Railway system for the past six years, has been advanced to the position of superintendent of the Pawtucket Street Railway, and will, in addition, have entire charge. Mr. Cooke succeeds Mr. Charles F. Luther, who was connected with the Pawtucket corporation for more than a dozen years.

MR. CHARLES OLIVER, Chief Railroad and Tramway Commissioner of New South Wales, who has been making his headquarters while in New York with R. W. Cameron & Company, 23 South William Street, expects to sail on Aug. 11. By that time Mr. Oliver hopes to have completed the awarding of contracts for the extensive work being done on the Sidney railway system. The General Electric Company has undertaken the contract for supplying the equipment of the main power station, and it is stated that nearly all apparatus, engines, material, etc., will be furnished by this country. The work is expected to continue for at least two or three years, so that it is quite possible that Mr. Oliver may favor the United States with another visit in the near future.

NEWS NOTES

[*News notes for this department are solicited.*]

DERBY, CONN.—The Derby Street Railway Company has decided to abandon Lake Housatonic Park as a pleasure ground.

BRIDGEPORT, CONN.—The stable of the Bridgeport Traction Company was destroyed by fire Aug. 1. Seven horses were burned to death.

NEW HAVEN, CONN.—At the annual meeting of the stockholders of the Winchester Avenue Railroad Company, July 30, Israel A. Kelsey was deposed as director of the corporation and at a subsequent meeting of the directors Mr. Kelsey was deposed as vice-president, Samuel Hemingway being elected to both positions. Mr. Hemingway is also vice-president of the Fair Haven & Westville Railroad. Henry S. Parmelee was re-elected president, Henry F. Spencer secretary, and Albert E. Pond, treasurer and superintendent. The following directors were elected: Henry S. Parmelee, S. Harrison Wagner, Albert E. Pond, Henry F. Spencer, Samuel Hemingway, John B. Carrington, E. Hayes Trowbridge, George D. Watrous, James S. Hemingway.

WASHINGTON, D. C.—The Washington Traction & Electric Company has just completed the extension of its lines from North Capitol Street via Michigan Avenue to the Catholic University, where connection is made with the old Brookland Street Railway. The cars are now run from Penn Depot to Brookland over the new route, and its city lines. The use of the tracks from Albany Street to the Catholic University has been discontinued at least for the present. Work is rapidly progressing on the rebuilding of the Washington Traction & Electric Company's tracks in Eckington.

SAVANNAH, GA.—It is said that the Savannah, Thunderbolt & Isle of Hope Railway Company will shortly make application to the City Council for permission to lay a second track on Barnard Street, and two switches on Whitaker Street. This action will be preliminary to a change in the operation of the lines.

CHICAGO, ILL.—While going north in Superior Avenue, South Chicago, a few nights ago an electric car of the South Chicago City Railway left the track and ran on the sidewalk in front of 8421 Superior Street, demolished the car and injured two passengers.

CHICAGO, ILL.—Traffic on the Metropolitan Elevated during July showed a daily average of 73,790 passengers, as compared with 67,498 during the corresponding month of last year. This is a gain of 6292. The gain is small, and this is due to the labor troubles, which have had a severe effect on West Side travel. The traffic by months, with a comparison for 1899, follows:

	1899	1900
January	72,338	88,585
February	75,344	92,618
March	79,243	94,508
April	77,464	90,430
May	75,890	86,288
June	72,433	82,206
July	67,498	73,790

CHICAGO, ILL.—The Appellate Court has sustained the decree of the Circuit Court, made in July, 1897, ordering the sale of the Alley L elevated road and its appurtenances and the division of the proceeds between the two mortgages. There were no new legal points covered, and the decision is of importance only to the stockholders of the company operating the road, whose title is strengthened. The Chicago and South Side Rapid Transit was built in two sections, the first section extending from Congress Street to Sixty-Third Street, and the second section from Calumet Avenue to Stony Island Avenue, along Sixty-Third Street. To pay for the construction of the first section bonds to the amount of $7,000,000 were issued, and secured by a trust deed on the section, made to the Northern Trust Company as trustee. To pay for the construction of the second section bonds to the amount of $3,000,000 were issued, and secured by a trust deed on both sections, made to the Illinois Trust and Savings Bank as trustee. On default of interest the Northern Trust Company asked foreclosure of the first mortgage on the first section, and the next day the Illinois Trust and Savings Bank filed a cross bill for the foreclosure of the blanket mortgage on both sections. The court ordered the property sold, the proceeds to be divided between the two sets of bondholders, in the proportion of 75-93 to the first set and 18-93 to the second set. The property was bought in by the bondholders and divided between them in that proportion. The stockholders of the original company claimed that the whole bond issue was void; that the franchise forbade any company but the original one ever to own the road, and that the practical result of the foreclosure was to wipe out and destroy the property interests of the stockholders in the original company.

CHICAGO, ILL.—South Side Elevated traffic during July showed a daily average of 60,972 passengers, as compared with 52,644 for the corresponding month of last year, or an increase of 8328, equal to 15.8 per cent. The record is the smallest this year up to the present time, as July is a poor month for elevated road travel. The record so far this year, with a comparison with 1899, follows:

	1899	1900
January	58,762	69,504
February	60,292	70,050
March	63,909	72,264
April	63,878	71,665
May	50,588	68,296
June	56,117	67,892
July	52,644	60,972

ANDERSON, IND.—The perversity of a citizen of Summitville resulted in a funny legal complication a few days ago. The citizen in question having received a permit to move a house, proceeded with the work in the day. In its course the house was to cross the tracks of the Union Traction Company, and as soon as the officials of the company were advised of the movement they obtained a restraining order. The order was served just as the house was crossing the tracks, and the men when served with the notice immediately quit work, and left the structure on the tracks. The company then brought mandamus proceedings, and the court ordered the building taken away, but the men refused because lawyers advised them that the restraining order had not been dissolved. The company went with a force of men to remove it, but were stopped by the citizens. Passengers were transferred around the house, from one car to another, until the legal difficulties were overcome.

INDIANAPOLIS, IND.—The interurban electric railways entering this city still protest against the provisions of the franchises offered them by the city. The objections are against the clauses which require universal trans-

Annual Meeting of the Pennsylvania Street Railway Association Postponed

The annual meeting of the Pennsylvania Street Railway Association has been postponed until Oct. 10 and 11, and will be held at the Neversink Mountain House, Reading, Pa.

New York Convention Postponed

The eighteenth annual convention of the New York State Street Railway Association, which was to have been held at Buffalo Sept. 11 and 12, has been postponed until Sept. 18 and 19, at the same city. The postponement is made because of lack of hotel accommodations for the week commencing Sept. 10, as a number of other conventions are scheduled for this city at that time.

Municipal Ownership Ordinance Drafted for St. Louis

The Board of Public Improvements has drafted an ordinance, to be presented in Council, which provides that the city operate by electricity the railway extending from the Baden station of the waterworks to the Chain of Rocks. The road, at present, although owned by the city, is operated as a branch of the Burlington Railroad, and is used exclusively to transport the necessary heavy freight between the two branches of the waterworks system. The ordinance also provides for placing regular passenger coaches on the line, and for their regular operation by the city in competition with the private city lines in the vicinity.

Transfer Privilege to be Curtailed in Washington

It has been announced that the Washington Traction & Electric Company will make a number of very important changes in its transfer system, to take effect Aug. 15. A new transfer schedule has been arranged, but the most important change is that which abolishes the double transfer. Hereafter a transfer will not be issued on a transfer, but only when a cash fare is paid.

Before the consolidation of the roads now comprising the Washington Traction & Electric Company, no transfers were exchanged except between the Metropolitan and Columbia railways, and in some cases it required three fares to go from one point in this city to another. The consolidation of the separate lines and the issuance of transfers on transfers made it easy for a passenger to start from and return to a given point on one cash fare. In order to prevent this "looping" the company later required the passenger to state, at the time of paying his fare, at what point and in what direction a transfer was desired. Failure to comply with this order forfeited the right to a transfer.

New Haven Company Establishes a Precedent

On Aug. 1 the Winchester Avenue Railroad Company, of New Haven, Conn., issued an edict which prohibits passengers from riding on the running board of a car or from standing between the seats of a car on its system. This is an entirely new departure in street railroading, and the outcome will be watched with great interest throughout the country. The conductor is given to understand that just as soon as all the seats in the car are filled he must refuse to take on even one more passenger until a seat is made vacant by a passenger getting off. It must be said, however, of the new ordinance that it is a little severe on the motorman. He is required to keep a sharp lookout and to know when there are no vacant seats. As soon as his car is full, he is to proceed until signalled by the conductor to stop, or in case of an emergency. If passengers be waiting for the car, he is to slow up, not stop, and request them to wait for the next car.

A Unique Accident

A motorman working on the Waukesha interurban line of the Milwaukee Electric Railway & Light Company, and who wore celluloid collars because they were inexpensive, was seriously injured a few days ago because of his efforts to reduce his laundry bills. On Aug. 5 he noticed that his car was wrong, and, leaning over to adjust the switch, he turned on the current. Suddenly there was a flash and a spark flew out from the controller box. The motorman's collar was a shining mark, and it was ablaze before he realized what had happened. Before he could tear it from his neck, a broad band had been burned around his throat, his hair and eyebrows had been singed, and his hands burned by

the melting celluloid, which clung to his fingers. It was necessary to take the man to the hospital. Largely, it is said, on account of this accident, President Roach, of the Union Traction Company, of Chicago, has issued an order prohibiting his men from wearing celluloid collars, and it is thought that motormen in other cities who have worn this material will hereafter discard it for the more easily soiled but less combustible linen.

An Interesting Opinion in a Bicyclist's Suit

A most interesting opinion has recently been written in the case of Bacon vs. Consolidated Traction Company by the judge of the Court of Common Pleas, Allegheny County, Ill. The facts were that the plaintiff, an inexperienced bicyclist, rode on to the tracks, when a car proceeding on a down grade was "right behind him," and started to ride a distance of about 160 ft. and then turn off from the tracks. Just as he was turning off, after having gone about 140 ft. without having looked back at the car, he was struck by the car with the result, as the judge says, that "he was whirled in the air and came down, doubtless on the ground." The judge dismissed the suit for damages brought against the car company, on the ground that the plaintiff "was guilty of negligence, gross negligence, absolute recklessness." The judge then went on to say: "I have long been impressed with the belief that the courts should take a firm hold of these cases, where men risk their own lives by just going before a car or traveling on a track before a car. If the plaintiff can be sustained in this action, the result of it is about this, that these bicyclers can get on to the track of a street railway, plod along on that track, and expect that the motorman of the car behind will stop to let them off rather than hit them, and if that is the law with these bicyclers, perhaps one-half the cars in the city will be delayed in their trips. Some of these young fellows and others run before the car and expect the car to stop while they get out of the way. They should get out of the way without that. They should keep out of the way, and not run the risk of an accident." Finally, and apparently in the interest of humanity, the judge concluded his opinion with these words: "It is almost a wonder that this man was not killed by that accident, and by sustaining his right to recovery here I think it would result in somebody else being killed; it should rather be a warning to these bicyclers to keep off the tracks when they know a car is coming and avoid those dangers."

Early Opening of the Stephenson Plant

Joseph C. Willetts and Adolph Wimpfheimer, purchasing committee of the newly incorporated John Stephenson Company, have taken title to the plant, equipment and material of the late John Stephenson Company, Ltd., at Bay Way, near Elizabeth, N. J. Peter M. Kling, the general manager, is in charge, and will soon have the works in active operation. The officers of the new company will shortly be chosen.

Outing of Metropolitan Street Railway Officials

On Aug. 11 President Vreeland, of the Metropolitan Street Railway Company, of New York, entertained all the heads of the departments on that road at a clambake and reception at his country home in Brewster, N. Y. This is the second of a series of such entertainments extended by Mr. Vreeland, the first having been given about a year ago, and typifies the cordial friendship existing between the president and personnel of this large company.

The guests left the Grand Central Station about 9 o'clock on special cars attached to the Pittsfield express. After their arrival at Brewster, they were taken by carriages to the clubhouse of the Tonetta Outing Club, of which Mr. Vreeland is a member. The Brewster cornet band gave a concert, after which the Rhode Island clambake was eaten, some fishing was enjoyed, and the party again entered the carriages and was driven to Rest-a-While, the Vreelands' country home. Here they were cordially received by Mrs. Vreeland, who was assisted in receiving them by a number of ladies living in Brewster. In a speech of welcome Mr. Vreeland spoke feelingly of the support the employees had always accorded him. Responses were made, and he was assured of the esteem and regard in which he was held. Luncheon was served on the lawn, under the personal supervision of Mrs. Vreeland, the lawn being brilliantly illuminated, and the party returned to New York by special train.

Among those present from the company were: D. B. Hasbrouck, vice-president; Charles E. Warren, secretary; H. S. Beattie, treasurer; directors, H. P. Whitney, Thomas F. Ryan, W. L. Elkins, Thomas Dolan, P. A. B. Widener and H. A. Robinson; also, F. S. Pearson, consulting engineer; M. G. Starrett, chief engineer; W. B. Reed, engineer maintenance of way; W. A. Pearson, electrical engineer; F. Greenwald, track master; Thomas Millen, general master mechanic; A. C. Tully, purchasing agent and general storekeeper; A. V. Porter, architect; D. C. Moorehead, general auditor; Frank Kane, chief of gripmen; George Brown, chief of switchmen; George Robinson, general car-house foreman; Oren Root, Jr., assistant general manager; James Parker, chief inspector, and a number of the division superintendents and general foremen.

Among others in attendance were: W. W. Wheatley, general superintendent, Brooklyn Rapid Transit Company; W. W. Snow, president, Ramapo Iron Works, Hillburn, N. Y.; D. M. Brady, president, Brady Brass Company, of executive committee, New York Railroad Club; Edward W. Maher, president, Union Railway system, New York; G. Tracy Rogers, president, Binghamton Street Railroad Company; John Beaver, treasurer, Third Avenue Railroad Company; J. H. Hustis, superintendent, New York & Harlem Railroad; H. A. Macdona, and J. H. McGraw, of the Street Railway Journal.

Accident Instructions in Ithaca

H. S. Cooper, general manager of the Ithaca Street Railway Company, of Ithaca, N. Y., has recently issued to his conductors and motormen a comprehensive set of instructions as regards accidents. The instructions are in book form, and each copy is numbered. A list is kept of the copies issued, and each recipient is obliged to sign a receipt promising to return the book to the company when leaving its employ, or on request.

The pamphlet contains the telephone numbers and addresses of the different offices and officials of the company.

A special effort was made by the management to make the instructions full, explicit and *legal*, and for this reason they are given below as being possibly of help to other companies who issue instructions of this character.

INSTRUCTIONS

These "Instructions" are the exclusive property of the Ithaca Street Railway Company, and are issued solely to the employees of this company for their information and guidance while in the employ of the company. When employees to whom they are issued leave the service of the company, these instructions *must* be returned to the office of the company. All employees are forbidden to give, lend, sell or show these instructions to *anyone*, or to communicate any part of the contents to any person not regularly in the employ of the company. General Manager.

Every disturbance on, or occasioned by the cars, every collision or derailment, every accident to individuals or to animals, vehicles or property not belonging to the company, if such occurrence is caused by the cars, by their operation or by the act or operation of any employee of the road when engaged in duties for the company, *must* be reported to the office in some way.

Accidents to the car or its machinery, to track, bridges, or overhead line, derailments and collisions, loss of power, any and all of the foregoing which delay a car sufficiently to make it "lose its time" and which do *not* result in any injury to individuals or do *not* affect property belonging to outside parties, must be reported on the back of the car report in the form arranged for it.

Accidents which involve the *slightest* injury to any individual or the *slightest* chance of a *claim* for injury *must* be reported at once on the regular "Accident Report" of the company in the manner as prescribed further on. Accidents which involve any animals, vehicles or property *not* belonging to the company *must* be reported on the same form and in the same way. All disturbances on or occasioned by the cars, all ejections, no matter for what cause, must also be reported on this form.

In the matter of accidents to individuals, it must *never* be assumed that "no harm has been done," no matter what the individuals say themselves. The assumption must always be that "harm *has* been done" and the report must be as promptly and accurately filled, and names of witnesses, etc., taken with as great care as if actual and visible injury had been inflicted. Much loss has been occasioned to companies by the neglect of employees to properly report cases of accidents which seemed trivial at the time of occurrence but which developed into important and expensive cases. The invariable rule must be: *To report every accident to individuals with full and equal care.*

(1) Upon the occurrence of any accident the *first* duty is to render assistance to the person or persons involved in it. In case of bodily injury they must be taken or carried to the nearest hospital, doctor's office, drug store, store or dwelling and a doctor summoned at once. The instant that a doctor or other competent person (such as a nurse or relative) arrives, the injured person will be left in their charge and you will at once proceed to fulfil your other duties in the matter.

In case of accidents to animals, vehicles or other property, any needed assistance *must* be given to the riders, drivers or owners.

(2) The *next* duty is to obtain the *full and correct name and address* of the person or persons injured or of the riders, drivers or owners of animals, vehicles or property injured or damaged.

(3) The *next* duty is to obtain the *full* and *correct names and addresses* of all bystanders and eye-witnesses. If the accident is on or caused by a car, the name and address of *every* passenger must be obtained. For this purpose, the "witness slips" will be distributed to *every* passenger and to *every* bystander, and they must be politely asked to "please write their full name and address on them and give them back to you." If they refuse to do so, or seem very unwilling to do so, you will urge them to do it, or will ask them to give you their name and *you* will put it down. If they still refuse, or seem unwilling to give their names, tell them that it is a strict rule of the company and that your failure to obtain their names and addresses will be a detriment to you, as your failure to obtain names of witnesses will look as if you had not tried to obey the rules of the company. In case you are then unable to obtain their names and addresses you will, in case they were passengers or bystanders who you are pretty certain were witnesses of the accident, try if others around know them or can give you their names, and if such information cannot be obtained, you will take good notice of them so as to be able to recognize them at any time in the future. Every effort *must* be made to obtain *the names and addresses of all possible witnesses;* it is better to obtain a hundred useless ones than to miss a single person who *was* a witness of the event. In this matter the operation of the car *must be a secondary matter;* the motorman will remain with and in the car, unless he is incapacitated by injury or unless his assistance is absolutely necessary with the injured, and he will then go only a short distance away, and will, before leaving the car, make certain that the brake is on tight, and will throw the overhead switch and controllers to "off" and take both controller handles with him. In case, however, of another motorman or conductor being on the car or coming to it, he will leave the controller handles and care of the car with him. In no case must the car be started until the above duties have been fulfilled, unless relieved by the arrival or the direct orders of the starter, inspector, general manager or corporation counsel.

(4) The *next* duty, in case of actual bodily injury, is to notify the officers of the accident by the *quickest possible method.* If the office is closed, the general manager, corporation counsel or inspector *must* be notified wherever they can be reached or found. All employees are empowered to go to any necessary expense for telephone charges or special messengers for this purpose and the numbers of all company telephones and the addresses of the above persons are attached herewith for your information.

(5) The *next* duty is to make out the report. When the corporation counsel or his assistant is in his office or when they can be reached in any way, the report will be made out under their supervision and will be sworn to at once. In cases of bodily injury, where the above parties are absent from the office or cannot be reached, the report must be filled out *under the supervision of the inspector or general manager.* As one of the objects of the report is to fix the facts while they are fresh in the minds of those concerned in the event, *it is necessary that the report be made out as soon after the event as possible,* and therefore employees concerned in any accident, etc., will be immediately excused from their regular duties in order that they may make out such report. The other object of the report is to obtain ALL THE FACTS EXACTLY AS THEY OCCURRED. For this reason, opinions and "hearsay" are *not* wanted in it, what *is* wanted is for each employee to tell truthfully and exactly what he did and said and what he saw and heard others concerned do and say, *not* overlooking any detail, however trivial, *not* making excuses for or glossing over any forgetfulness or carelessness on his part or the part of anyone else, simply giving THE FACTS, ALL THE FACTS, AND NOTHING BUT THE FACTS as seen and heard and done by himself. The following instructions from the accident report should be carefully read when making out the report and the provisions *exactly* followed.

"NOTE.—Read the following instructions carefully before filling the above space. In case of accident, however slight, by which persons or property are injured, communicate at once with the office, by telephone if possible. Render all possible assistance to the injured, and at once obtain names and addresses of persons in car and other witnesses to the accident. In making this report, a separate report is to be made out by the conductor and motorman, and their position on the car at the time of accident should be shown. State clearly and briefly just what occurred, as you saw it. State conditions of weather and any obstacle which obscured your vision. State fully the nature of injury to persons or property. Give your reasons why you could not prevent the accident, and state what you did to prevent it. State whether person injured was lame, deaf, intoxicated or of defective vision; and give his or her approximate age. If property was injured, describe condition of property. State any act done by the person injured or whose property was injured, or any circumstances connected with such person, which in the slightest degree contributed to the injury. State what, if anything, was said by the person injured immediately after the accident, and give such further information as you may deem important. Avoid making any statement concerning the accident to outside parties."

(6) The *next* duty is to report for your regular duties and HOLD YOUR TONGUE! Under *no* consideration must the matter be discussed with or any information given to anyone outside of the proper officers of the company. *No excuses or accusations must be made or refuted at the time of the accident nor afterward.* Relatives, friends, fellow-employees, lawyers, reporters and the general public who try to obtain information from you in regard to the event *must* be informed that for you to discuss it *at all* or to give *any* information in regard to it is *positively forbidden* by the rules of the company, and they *must* be referred for such information to *the proper officers of the company.*

To recapitulate:

1. Render necessary assistance.
2. Obtain full and correct name and address of person or persons injured, or of riders or drivers or owners of animals or vehicles or property injured.
3. Obtain full and correct name and address of all possible witnesses.
4. Notify office or officers.
5. Make out report.
6. Report for your regular duties and hold your tongue.

6a. KEEP ON HOLDING YOUR TONGUE!

EJECTIONS

Passengers will be ejected from a car only as a last resort, when all other means have been tried and have failed, and when the conductor is *positively certain* that he is in the right.

Ejections must be made for the following reasons only:

1. Intoxication.
2. Personal offensiveness to the other passengers.
3. Refusal to obey rules of company.
4. Refusal to pay proper fare.
5. Disorderly conduct.

(1) Persons who are *visibly* intoxicated must not be allowed to get on the car. If, however, such a person has entered the car without his condition being noticed, he may, if his condition is not offensive and if he remains orderly, be carried to his destination. If this is done, care must be taken to see that he does not get off the car while it is in motion, and, when he is let off, care must be taken to see that he is entirely free of the car before it is started. Should his condition be complained of as being "offensive" by other passengers in the car, or should his conduct become "disorderly" he must be treated as ordered below.

(2) Any person who is complained of by the other passengers as being personally offensive and who is, in the judgment of the conductor, *actually so,* must be *quietly* asked to leave the car. Should they object or resist, they must be treated as disorderly persons, as below.

(3) Persons who persistently or continually refuse to obey the rules of the company after same have been brought to their notice, must be treated as disorderly persons, as below.

(4) In case of persons who absolutely refuse to pay the proper fare or give the proper ticket, the conductor will have to exercise discretion. When the person is a respectable woman or man who is sober and of respectable appearance it is generally best to carry such persons to their destination or to their transfer point, taking their name and address, their reason for nonpayment of fare or ticket, and in *every case* reporting the occurrence *in writing* to the office. When, however, any person shows plainly that it is their intention to "beat their way," they must be treated as disorderly persons, as below.

Persons giving a wrong transfer or one which is past time for proper use, must be asked to pay their fare and informed that if the transfer has been wrongly punched or given, it will be redeemed at office of the company on presentation and explanation. Should they persistently refuse to pay their fare, the transfer will be

accepted as fare, will *not* be rung up, but will be turned into the office with a *written* report of the occurrence and the name and address of the person presenting it. In no case must a person be ejected for presentation of a wrong or past-due transfer unless the conductor has *positive* proof that they are trying to "beat their way."

(5) Disorderly conduct consists of the above as stated, of violent or unseemly actions, of quarreling and fighting, and of abusive, threatening, profane or indecent language or actions. In all such cases the conductor will quietly and civilly request the disorderly persons to discontinue their conduct. Should this *request* have no effect, he will, still civilly and quietly, *tell* them to discontinue their conduct or leave the car. Should this be of no avail, the car must be stopped, at a street corner if possible, and the person asked to get off. Should they refuse to do so and a policeman be within call, he must be called and asked to remove the person. Should no policeman be within call, or should he, if called, refuse to remove the disorderly person, the motorman must be called on and the person ejected.

In all cases of ejections the car must *first* be brought to a *full stop*, at a street corner or regular stopping place if possible, and always at a *safe place* for a person to alight. If the person has paid their fare or given a ticket or transfer, the same will *always* be *publicly* tendered them BEFORE EJECTION.

No more force must be used than is necessary to remove them from the car, *no blows must be struck nor weapons used* by either conductor or motorman except in absolute defense of themselves or their passengers. In case the person voluntarily leaves the car or shows that they are willing to do so, no hand must be laid on them, except to assist them in case they are unable to get off without assistance.

No ejectment must ever be made of a child or a respectable woman. No ejectment must ever be made of any respectable appearing or sober man during a storm or at night in a dangerous or disreputable location.

In all cases it is necessary that the conductor feel *certain* that he is right beyond question before he proceeds to final measures, he *must* keep his temper and his presence of mind. While it is his duty to preserve order and decency on the cars, to see that people do not cheat the company, and to see that the company's rules are strictly obeyed and its property protected, it is best, if there is any doubt in his mind as to his being in the right, to carry such persons to their destination or to some point where he can obtain aid or advice.

In all cases of ejection the *conductor has entire charge and responsibility.* If the disorderly conduct is against the motorman or if seen or heard only by him, he will call the attention of the conductor to it and abide by his decision and orders. He will at all times aid the conductor when called on to do so or when he sees, hears or knows that his aid is required.

In every case of ejection a full report must be made out, the same as in accident cases. Equal care must be taken to obtain names and addresses of witnesses and in all cases of ejection it is best, *if it is in any way possible,* to make the ejection in the presence of witnesses.

Some Notes on Train Resistance.*

BY T. LESTER DANIEL, UNIVERSITY OF MINNESOTA

The subject of train resistance is one of two-fold interest to the railway mechanical engineer of to-day. It is of interest first because of its close relation to tonnage rating, and second, because of the direct saving in expenses accruing from its reduction. The Lake Shore & Michigan Southern Railroad, in 1873, figured that $785,000 a year could be saved by reducing train resistance 25 per cent, but in spite of the incentive to effort in this direction train resistances are the same to-day that they were then, because, undoubtedly, railway men are too busy to go beyond the routine of their regular work, certainly not because perfection in this respect has been reached.

It seems as though a reduction of 25 per cent were easily within the range of probability, inasmuch as Wellington (Trans. A. S. C. E., April, 1873), has shown that a reduction of 85 per cent in axle friction could be made by substituting oil bath lubrication in place of the common pad lubrication now in use, and when it is considered that axle friction constitutes by far the largest part of train resistance, and that there is further chance for its reduction by changing bearing metals, proportion of journals, and quality of lubricant, it is seen that there is opportunity for considerable improvement, to say nothing of the saving that might be made in the imperfectly understood rolling friction.

Tonnage ratings could be made much more accurately with a better knowledge of the factors composing train resistance, for a knowledge of the factors as well as the sum total is essential, as can be seen from the following: The proceedings of the Western Railway Club, February, 1900, cite an instance where a rise in temperature lowered the resistance 24 per cent, and the C., B. & Q. Railroad tests (*Eng. News,* 1888, p. 409) show that a strong side wind increases the resistance 60 per cent. The above number of the proceedings of the Western Railway Club also records an instance where a train of empty cars pulled harder than a train of loaded cars by .7 per cent per ton, and these factors, *i. e.,* empty cars, temperature and wind, have received so little attention that they have never been incorporated in the common formulas for train resistance. Obviously, a better understanding of these would result in a much more satisfactory tonnage rating.

Train resistance is generally expressed in pounds of draw-bar pull per ton of weight hauled on a straight and level track; it amounts to about 6 lbs. at 10 miles per hour, and 16 lbs. at 60 miles per hour; it is seen to increase with the speed, which is in accordance with the well-known experimental laws of friction. In colder and windy weather the few isolated observations that have been made indicate that the resistance would be larger, and many other changes besides that of velocity might be imposed affecting the result, but unfortunately experiments have been restricted almost entirely to velocity variation, as illustrated in the following typical formulæ:

Clark, $R = 6 + \frac{M^2}{240}$

Baldwin Locomotive Works, $R = 3 + \frac{M}{6}$

J. B. Blood, $R = 4 + .15\,M + .3\frac{M^{1.8}}{T}$

(Street Railway Journal, March, 1899.)

in which R is the resistance in pounds per ton; M, speed in miles per hour; and T, the tons hauled. These differ quite materially in form, although they all give reasonable results. Many others have been proposed, but probably none give better results than that of Blood. He has a term increasing with the 1.8 power of the velocity, which seems reasonable, for it harmonizes with experimental laws. Laws of solid friction state that it varies directly with the first power of the velocity, while laws of fluid friction state that it varies with the square of the velocity. Now, in case of car journals, we have neither a case of solid nor a case of fluid friction, but a case of mixed friction, and it seems reasonable that it should partake of the nature of both solid and fluid friction, and that its exponent should be neither 1 or 2, but some intermediate value. This term also decreases as the tonnage increases; this agrees well with the admirable experiments made by Thurston, where he shows that, within the limits of railway practice, the coefficient of friction decreases as the pressure increases.

The fact that different experimenters obtain different results is no particular cause for distrust; it means that experiments are carried on under different conditions, and until uniform conditions are prescribed and accepted uniform results cannot be expected; different conditions of lubrication, or different lubricants, may be responsible for the resistance varying anywhere between the first and second power of the velocity, for the magnitude of this kind of friction is determined by the nature, quantity and method of applying the lubricant. The condition of bearings, condition and size of wheels, condition of rails and roadbed, also affect the result, together with temperature, wind, number of cars, velocity, grades, acceleration, air friction and curvature of track.

The resistance due to curvature depends on its compensation, elevation of outer rail, kind of couplers, whether rigid or flexible head, length of wheel base, and probably upon the kind of trucks used. Formulæ proposed at different times for some of these factors are:

Acceleration, $R = .0132\ V^2$

Rolling, axle and air friction, $R = 4 + .15\,M + \frac{M^{1.8}}{T}$

Grade, $R = .38\ G$

Curvature, $R = .438\ D$ (at 25 miles per hour)

where R = resistance in pounds per ton, M = miles per hour, T = tons hauled, G = grade in feet per mile, D = degrees curvature, and V = speed attained in one mile, in miles per hour. Air friction amounts to about 4.2 lbs. per car; assuming a loaded car to weigh 45 tons, this amounts to .093 T = R; rolling friction is generally taken at 1 lb. per ton (Trautwine) and is due to the rail resisting the progress of the wheel.

The increased resistance due to curvature at a velocity of 25 miles per hour has been analyzed as follows (Trans. A. S. C. E., April, 1878):

* Paper read before the North-West Railway Club, May 15, 1900.

Due to twist of wheel.....	.001	lbs. per ton per degree
" slip of wheel.....	.1713	" " "
" flange friction.....	.2450	" " "
" loss at coupling....	.0213	" " "
Total.....	.4386	

The "coning" of wheels increases this from .125 to .25 lbs. per ton per degree; loose wheels reduce this loss 20 or 25 per cent.

The increased draw-bar pull due to tonnage made up of empty cars is partially due to increased air friction and partially due to increased co-efficient of friction at lighter pressures. (Thurston, "Friction and Lost Work in Machinery and Mill Work," p. 304).

The following results for train resistance were obtained from a dynamometer car test made by the Minneapolis, St. Paul & Sault Ste. Marie Railway last winter, and while the results are not as uniform as could be wished, they are as satisfactory as those usually obtained:

No.	Pull in Pounds	Mile Post	Grade in Feet to the Mile	Resistance in Lbs. Per Ton	Miles Per Hour	Remarks
1	24,000	44	42	5 16	6.5	
2	25,000	45	42	6.05	5.8	
3	25,500	48	28	11.8	2	All cars on 4° curve
4	25,750	48.59	42	6.66	4.1	
5	11,000	59.5	Level	9.66	15.3	
6	11,750	68	7.67	7.41	19.8	
7	8,200	70.25	Level	7.2	20.5	
8	5,700	89.75	Level	5.01	26.5	
9	8,100	92.31	Level	7.11	22	
10	24,200	102 32	42	5.35	8.1	
11	28,000	103 4	42.2	8.6	4.9	
12	11,250	109.5	3.69	8.5	19.2	
13	6,900	118.66	Level	5.41	24.4	
14	7,200	126.4	Level	5.64	26	
15	24,250	133.19	42.2	4.76	8	
16	19,100	133.49	29	3.92	9.5	
17	7,400	136.62	Level	5.8	24.7	
18	10,560	141.11	5.28	6.26	20	
19	15,100	146.63	14.72	6.25	17	

The train consisted of thirty-five loaded cars, with a total weight of 1139 tons, tare 474; at Weyerhaeuser (Mile Post 114) the train was increased to thirty-nine cars, 1277 tons. Results were deduced from the draw-bar pull, P, and the grade, G, and the tonnage, T, by the following relation:

Work per mile $= P \times 5280 = Rt \times 5280 + 2000\ G\ T$ where the work is expressed in foot-pounds and Rt is the total frictional resistance due to axle, rolling and air friction; solving for Rt we have

$$Rt = P - \frac{200\ G\ T}{528}$$

Dividing this by the tons hauled gives the resistance in pounds per ton as tabulated in column five; these correspond closely to the formula $R = 5.25 + .072\ M$ where R is the resistance in pounds per ton and M is the miles per hour. As can be seen, the run was made with a freight train and with a small range of velocities, 2 to 27 miles per hour.

In order to ascertain in any case if the tonnage is so large as to produce frictional resistances beyond the capacity of the locomotive, all the various resistances, rolling, axle, air, grade, curvature, etc., as given above, are added together, giving Rs the sum of all the resistances for the particular place in mind; then the draw-bar pull, P, required is found from

$$P = Rs\ T + \frac{G\ T}{5280}$$

which may be compared with the known pull which the locomotive can exert. If the train can have a speed, M, at the foot of the upper grade, it may ascend a hill steeper than that given by the above, *i. e.*,

$$= \left(\frac{P - Rs\ T}{T}\right) 5280,$$

for its momentum makes it capable of climbing a grade considerably beyond the apparent capacity of the locomotive. The force due to this momentum is found as follows:

Momentum $= mv$, where $m =$ mass of train $= \frac{\text{weight in lbs.}}{32.2} = \frac{w}{g}$;

and $v =$ velocity of train in feet per second. Now $v = at$, where $a =$ acceleration in feet per second and $t =$ time in seconds to acquire the velocity v, hence, $mv = \frac{w}{g} at$; but force $= f = ma = \frac{w}{g} a$;

therefore, $ft = \frac{w}{g} at = mv =$ momentum, and $f = \frac{mv}{t}$ where f is the force due to the momentum of the train of mass $m = \frac{w}{g} = \frac{t}{g} \times 62.3$ moving with a velocity v for t seconds. Reducing this to more convenient numbers for our purpose it becomes $f = \frac{T\ M}{t} \times 2.83$,

where f is the total force in pounds, T is the tons hauled, M=miles, per hour and t=time in seconds to ascend the grade; representing the length of the grade by L miles and taking the velocity at the foot of the grade at 30 miles per hour (for freight trains) t becomes equal to $\frac{2\ L}{30} = \frac{L}{15}$ and $f = \frac{T\ M\ L}{15} \times 2.83$ and the average force on the grade $= F = \frac{f}{2} = \frac{T\ M\ L}{30} \times 2.83$, hence the grade that can now be ascended is $G^1 = \frac{(P+F-Rs\ T)\ 5280}{T}$ where G^1 is in feet per mile.

Results of experiments up to date enable me to make such computations with very fair satisfaction for certain normal cases, but much further experimentation is needed, as the laws of train resistance are still unformulated.

"Every Ohm, Volt and Spark to be Registered"

When the average daily newspaper reporter undertakes to describe an electrical device he usually falls into many pitfalls, and his account is most fearfully and wonderfully made, but the following article from the Philadelphia *Evening Telegram* of Aug. 7 is one which would be hard to beat:

"The wattmeter is the latest addition to the duties of the trolley motorman, and is regarded by that individual as the most exacting of all the things he must keep under his eye, although in this instance he must keep it under his feet and never fail in doing so. If he does it ceases to work, and the object of the wattmeter is continuous work, for it measures the electric current and saves power.

"Heretofore, the motorman has had a comparatively easy time of it alongside the conductor. He has watched the street crossings, listened to the bell calls overhead, kept an eye ahead for trouble and children on the tracks, kicked the button on the floor, manipulated brake handle and electric bar as occasion demanded, taken his meals while on the jump, occasionally saw his family during the course of a day, and stood through every rain storm that came along, together with some other things, but there has never been a measure line on how he turned on or off power such as the conductor has in the line that keeps tab on the nickels.

"Now matters are to be different. The wattmeter will soon measure every ohm and volt and spark of current he applies to the wheels and wires of his car, and if he misses any—if the car goes too fast or the handle gets over the notch on the board too rapidly—the innocent-looking arrangement beneath his feet will tell it all, and he will be well employed. Both hands and feet will be constantly going—the right hand on the brakes, the left on the motor bar; the right foot on the warning gong and the left foot on the meter—and there will be no lost motion, for every movement will tell. This will enable him to sleep well at night.

"The wattmeter was introduced last week on Block 628 of the Tenth and Eleventh Streets line. It is an innocent-looking affair—just a square piece of black rubber that looks like an abbreviated doormat that can't be moved, and covers one spot all the time and at all times. It connects with the electric machinery of the boxes under the car, and tells tales of every movement of the current on a circular disc just like a gas meter tells the flow of gas. It has been in use in Pittsburgh over a year, and the inventor lives in that city. It is now in use in St. Louis and Chicago, and meets the object of saving the electric current handsomely. The motorman can't regulate it nor interfere with its workings in any way. He must keep his foot on it, however, all the hours the car runs, and it does the rest.

"The object of the wattmeter is to save power. The meter tells just how much current is necessary for every trip, and in Pittsburgh the motormen have just so many ohms at their disposal every day. If they get beyond they must explain. One day more than usual or the next day less than usual does not take from or add to any given surplus.

"The Traction Company now has special storage batteries in Germantown, on North Ninth Street, above Montgomery Avenue; at Fifth and South Streets, and at the foot of Beach Street, for the accumulation of power. During the hours of the day when travel is lightest power is held in check and stored away, to be sent out when travel is heavy and the cars need it. Heretofore this power has been wasted, but the wattmeter holds it in check the same as

gas and water are held back. The offices at Eighth and Dauphin Streets have a complete record of what is done, and when the wattmeter is generally in place on the car fronts inspectors will register every trip.

"A Union Traction Company employee said to-day: 'There is no knowing what this new arrangement will do, but it is coming. Everybody is interested, and nobody can explain it. That's the funny business about it.'

" 'What do you stand on it for?'

" 'I stand there to keep the current from passing through the bolts. That's all I know.' "

When this clipping was shown to Mr. Twining, chief electrical engineer of the Union Traction Company, he said, on recovering speech, that the wattmeter was of the usual G. E. pattern, and that it was put on to test the efficiency of some roller bearings the company is trying on one of its cars.

London Letter

[*From Our Regular Correspondent.*]

The new underground railway which the Central London Railway has opened to traffic this week has proved to be a great success, and all London seems to be as pleased with its latest novelty as a child would be with a toy. During the first day there were no fewer than 84,500 passengers who traveled by the new line, and thousands more stood about the stations and looked on. The universal verdict has been in favor of the new road, which has already been nicknamed the "Two-Penny Tube." The simplicity of the arrangements is also greatly appreciated, though the system of purchasing tickets and dropping them in "chopper" boxes at the gate, in the same manner as is done on the elevated roads in New York, is an absolute novelty to the public in this city. It is a system, however, which will commend itself to the public later on, and is already favorably commented upon. The luxuriance of the cars has also called for many remarks and one can hear on all sides favorable criticisms as to the lighting, the ventilation, the elegance, the comfort and the general pleasantness of the motion of traveling in this underground tunnel. For those who have to travel long distances the price of 2d. commends itself most favorably as the omnibus fare for the same distance amounts to 5d. The first day passed off with the greatest success, and everything worked as smoothly as if the road had been running for years. The majority of the public, however, did not know that for the past three weeks the directors have been running experimental trains at schedule time with the whole force of employees attending to the work just as if the road were open for traffic. In this way, therefore, when the road was thrown open everything started off with the greatest smoothness and each employee knew exactly what was expected of him. After a period of extreme heat in London, when the thermometer has been averaging 90 deg., for the past week or two the deliciously cool atmosphere of the tunnel has proved most grateful, the temperature being always in the vicinity of 55 deg. It may not be out of place to recall at this time that it is just ten years since the scheme was first promulgated, the first application having been made to Parliament in 1890. Since that time many of the most able and experienced engineers and business men who are familiar with railway business have been devoting continuous thought to the successful accomplishment of this railway. The company was actually floated in June, 1895, and the first operation was the sinking of the shaft at Chancery Lane in August, 1896. The cost of the double tunnel has been about £585,000 per mile, so that for the whole road the cost has been about £3,500,000. The line, as is well known, starts at the Bank, and goes to Shepherd's Bush, and is underneath great public thoroughfares throughout the entire length being directly underneath Cheapside, Newgate Street, Holborn, Oxford Street, Bayswater Road and Uxbridge Road. The journey by omnibus used to take one and a quarter hours, and as the running time on the underground road is only twenty-five minutes, it will be seen what advantages it possesses, especially when you can travel the whole distance for less than one half the 'bus fare. It looks as if the Central London Railway were destined to have a great success, and judging from the number of passengers who traveled during the first day, which, at the same rate, would be a yearly passenger return of 30,000,000, it looks as if it were quite possible that the estimated passenger traffic expected by the company of 50,000,000 would be soon realized.

The half-yearly general meeting of the Metropolitan Railway Company was recently held under the presidency of Mr. John Bell. After making a statement that the result of the half-year's working was that they carried to net revenue a balance of £202,004, out of which it was proposed to declare a dividend of 3¾ per cent per annum, Mr. Bell referred to the following clause in the report which had just been submitted:

"The arrangements, referred to in previous reports, for an experimental working by electricity between Earl's Court and High Street, Kensington, stations have been completed, and an electrical train has been working daily since May 31 last. In view of the importance to the Metropolitan and District Railway Companies of adopting electricity as a motive power, a committee consisting of three members from each of the boards of the companies has been appointed to consider the question of applying electric traction to the working of the Inner Circle, and it has been agreed between the companies to invite eminent electrical traction firms to submit plans and specifications, with detailed estimates and tenders for the necessary installation."

It thus seems very certain that before long part of the underground system at present operated by steam by the Metropolitan Company will be converted to electrical working. The directors have satisfied themselves by the experimental train which they have had working near Earl's Court for the past few months that it is quite possible to convert their system to electricity. The problem which they have is naturally one of considerable difficulty.

The Glasgow District Tramways Bill, which was promoted by William Murphy, of Dublin, which was passed by the Lord's committee last May, has just been thrown out by the select committee of the House of Commons, presided over by Sir Lewis M'Iver. The committee found that the preamble of the bill was not proved, but desired to put on record that in its view the original scheme was a good one, and calculated to be of much use to the district, but that the scheme had been so mutilated and loaded with conditions by the conflicting interests and the excessive demands of several local authorities that, at present, it appeared to the committee to be wholly unworkable. There seems no doubt that when the plan was first brought forward by Mr. Murphy for a system of tramways in Paisley and Renfrew that it was calculated to have been a great benefit in the vicinity of these two towns. Mr. Murphy, however, had to encounter the tremendous opposition of the Glasgow Municipality, and also had to encounter opposition from Paisley and Renfrew and other towns, each one of which insisted upon certain conditions being fulfilled, which, as the chairman of the committee stated, practically amounted to blackmail. The original scheme had therefore to become cut down to such an extent that there remained practically very little of it, and even Mr. Murphy himself now does not value it very highly.

The select committee of the House of Lords, of which the Earl of Camperdown is chairman, has had under consideration the bill promoted by the London County Council under which power is sought to enable the Council to use electricity as the motive power for trams which it already owns in the metropolis and other trams which, under the Tramways act, it may acquire. It was stated that the County Council already owned over 70 miles out of the 115 miles of line which exist in London, and by 1911, if the present policy of purchase is pursued, it will have acquired the remainder. The bill was opposed by the South Metropolitan Gas Company and the Lambeth Water Company, who feared that the proposal would cause electrolysis of their mains, and by the Lambeth and Wandsworth local authorities, who urged that they were not given adequate protection under the bill. Eventually the committee passed the preamble, subject to certain provisions being inserted for the protection of the gas and water companies. The Light Railway Commissioners, however, has refused to grant the order for the proposed electric tramways in Surbiton and Kingston, two suburbs of London, owing to the opposition of the local authorities and the Surray County Council.

An important report dealing with a proposal to construct a tramway extending along the Embankment from Blackfriars to Putney Bridge is being considered by the Chelsea Vestry. A certain scheme by which trams will be run by way of the Victoria Embankment, Victoria Street, Buckingham Palace Road, and the Chelsea Embankment to Putney has been approved by the improvements committee of the London County Council, subject to the local authorities in control of the various municipal areas through which the line will pass agreeing to contribute between them a third of the cost. Chelsea, it appears from the report, would have to pay as their share about £63,733, and the proposal is not regarded in a favorable light. The Vestry will be asked to point out to the London County Council that the money which would have to be expended on the trams would be spent to much better purpose if laid out for street improvements.

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

STREET RAILWAY PATENTS ISSUED AUG. 7, 1900

655,216. Switch for Suspended Electric Conductors; J. Floyd, Washington, D. C. App. filed Dec. 8, 1899. The main and branch

wires each have an upwardly turned open loop, affording a passage for the flange of the trolley wheel.

655,217. Crossing for Suspended Electric Conductors; J. Floyd, Washington, D. C. App. filed Dec. 8, 1899. A modification of the preceding.

655,305. Track-Sanding Device; G. W. Mudd, Moberly, Mo. App. filed March 22, 1900. The motorman is able to open a valve to admit a blast of air for driving sand out of the sand-box onto the track.

655,349. Railway Track Structure; H. B. Nichols, Philadelphia, Pa. App. filed May 1, 1900. The hardened plate or block forming a continuation of the crossing rail is supported and secured by a soft metal filling which serves as a cushion, and also as the sole means for locking the plate in position.

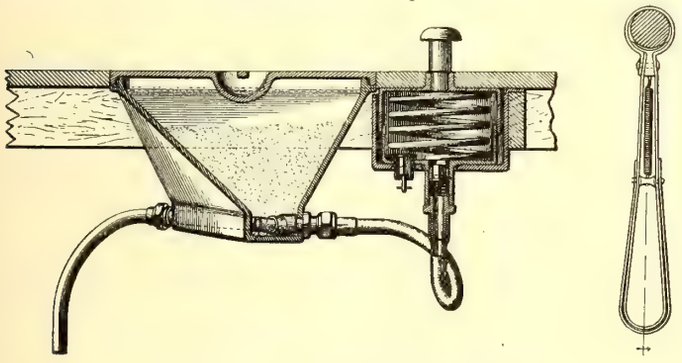
655,370. Rail-Joint; A. Relay, South Norwalk, Conn. App. filed Oct. 16, 1899. A projection from the end of one rail enters an opening in the end of the other, the two parts being shaped to interlock with each other.

655,386. Car Truck Frame; E. S. Woods, Chicago, Ill. App. filed Feb. 15, 1900. The frame comprises two parallel side frames, a transverse truck bolster detachably interlocking with each of the side-frames and removable springs between the bolster and side-frames designed to hold the bolster interlocked with the frames.

655,389. Safety Device for Electric Vehicles; F. E. Case, Schenectady, N. Y. App. filed May 20, 1899. In case the motorman becomes incapacitated, a device is attached to the controller, which cuts off the power.

655,400. Tie-Plate; W. Goldie, Wilkinsberg, Pa. App. filed Dec. 9, 1899. A metal plate upon which the rail rests, is provided with spurs to enter the tie and flanges to retain the rail.

655,428. Hand-Strap for Street Cars; T. E. Wardwell, Stamford, Conn. App. filed Feb. 3, 1900. The strap has two loops so that two persons may use it at once; one loop is retracted to an elevated position by a spring, so that it may be drawn downward for the accommodation of short persons.



PATENTS NOS. 655,306 AND 655,428

655,444. Tongue-Rail Fastening for Railways; P. Knittel, Crefeld, Germany. App. filed June 15, 1900. A fastening for a tramway tongue-rail consisting of a cross-key engaged in a slot of the tongue-rail pivot, and having its ends held in a slot of the base-casting.

655,449. Railway Switch; A. G. Moeckel, Detroit, Mich. App. filed April 22, 1899. The movable tongue is located in the hollow of a plate, and carries flanges which always cover the hollow to keep out snow and ice.

655,455. Electric Railway; W. B. Purvis, Philadelphia, Pa. App. filed April 24, 1900. The circuit is closed by a magnet carried by the car which lifts a flexible cable into contact with the terminals of the branch leading to the sectional conductor.

655,465. Car Truck; G. L. Stuedner, New York, N. Y. App. filed March 17, 1900. The wheels of the truck are flangeless, the function of the flanges being supplied by small wheels or discs independently mounted upon the truck.

655,566. Street Railway Car; G. Moore, Boston, Mass. App. filed Feb. 21, 1900. Details of construction pertaining to a flexible panel to be used in the construction of convertible cars.

655,634. Bearing for Car Trucks; C. H. Hartman, Allegany, Pa. App. filed June 4, 1900. The two bearing surfaces between the body and truck are provided with inclined faces between which balls are placed, the body being lifted when the truck turns, to reduce the friction at the bearing.

PERSONAL MENTION

MR. F. L. HART has resigned as general superintendent of the Washington Traction & Electric Company, of Washington, D. C.

MR. EUGENE E. HAWKINS has resigned as general superintendent of the New Paltz & Poughkeepsie Traction Company, of New Paltz, N. Y.

MR. D. F. BURRITT has resigned as general manager of the Palmer & Monson Street Railway Company and of the Central Massachusetts Electric Company.

MR. WILLIAM D. WEAVER, editor of the *Electrical World and Engineer*, of New York, was married last month in Bremen, Germany, to Miss Mildred E. Niebuhr. Mr. and Mrs. Weaver expect to sail for New York about Oct. 1.

MR. SAMUEL G. DE COURCEY has been elected president of the American Railways Company, of Philadelphia, to succeed A. A. McLeod, who recently resigned. Mr. De Courcey was born in Maryland and came to Philadelphia in 1863. He has been president of the Western New York & Pennsylvania Railroad since 1892.

NEWS NOTES

[*News notes for this department are solicited.*]

LOS ANGELES, CAL.—The Los Angeles Traction Company has made application to the City Council for three franchises for the extension of its lines.

DENVER, COL.—The Denver City Tramway Company has adopted a new bicycle carrier.

DENVER, COL.—The employees of the Denver City Tramway Company held a picnic on Aug. 8, the proceeds of which are to be devoted to the three athletic and literary clubs composed of employees of the company.

HARTFORD, CONN.—The Hartford Street Railway Company has equipped several of its open cars with eave troughs as a protection to passengers from the water which falls from the roof of the car during a rainstorm. The troughs run along the side of the car and are connected at the ends with a waste pipe which carries the water to the street.

HARTFORD, CONN.—The Hartford, Manchester & Rockville Tramway Company has announced through its president, M. S. Chapman, that hereafter every employee of the company who remains in its service five years shall be entitled to wear a service stripe, and also be entitled to an increase of 25 cents per day in wages. Five men, who have been in the employ of the company the required length of time, have been decorated with the stripe and receive increased pay.

WILMINGTON, DEL.—At the recent annual meeting of the stockholders of the Wilmington City Railway Company the following directors were elected for the ensuing year: John A. Rigg, Henry C. Moore, R. N. Carson, W. S. Bell, Thomas S. Bellah, Peter J. Ford and K. A. Fichthorn. No change was made in the management of the system. Numerous improvements have been made during the past year. Changes have been made in the tracks where necessary, new rails and switches being laid in some places. In fact, the entire Wilmington and Chester system has undergone improvement. A full equipment of summer cars had been provided for the Darby line and additional winter cars are now under construction.

JACKSONVILLE, FLA.—The Jacksonville Street Railroad Company has been successful in securing a franchise here.

CHICAGO, ILL.—The Chicago City Railway Company has ordered a number of convertible cars, and proposes to give them a thorough test this winter.

EAST ST. LOUIS, ILL.—The Granite City, Venice & East St. Louis Electric Railway Company has been granted an extension of six months, in which to complete the construction of its line. Work was stopped for some time by an injunction.

DIXON, ILL.—The City Council has passed an ordinance granting the Illinois & Rock River Electric Railway Company a franchise for the construction of an electric railway on River Street from the westerly line of Peoria Avenue to the city limits, or through the city. The franchise requires that construction work begin within one year, and that the line be completed and in operation within two years from the passage of the ordinance.

CHICAGO, ILL.—The Law Department of the city has been asked to decide the matter of the size of a bill a passenger may offer the conductor for his carfare. The matter has been investigated by counsel, who learned that Chicago has no ordinances on the subject. It is alleged that a conductor in charge of an Indiana Avenue car has in his possession a $10 bill belonging to a passenger, and which was given him three weeks ago for two fares, and that after repeated requests he has not secured the return of the change. It is to be made a test case.

NEW ALBANY, IND.—The New Albany Street Railroad Company has been granted a thirty-year franchise by the Council. There were two other bidders for the franchise.

WICHITA, KAN.—The Wichita Electric Railway & Light Company has decided to place its entire system in the hands of the Kings Daughters on Aug. 26. The young women members of the organization will act as conductors, and will generally have charge of the entire system. The entire revenue for that date will be donated by the company to the Children's Home fund.

ALBERT LEA, MINN.—The application of the Albert Lea & Geneva Lake Electric Railway Company for a franchise has been granted by the City Council. The franchise is granted for fifty years and requires that the company have 2 miles of road built and in operation within two years. A fare of 5 cents is to be charged for one continuous ride within the city.

BIDDEFORD, ME.—The Saco River Electric Railway has applied for a revival of its charter, which had lapsed under the statute.

ATLANTIC CITY, N. J.—The stockholders of the Atlantic City Passenger Railway Company have elected officers as follows: William H. Bartlett, president; G. A. Aldrich, vice-president; A. M. Jordan, treasurer; Eli M. Chandler, secretary; G. A. Aldrich, general manager; directors, G. T. Lippincott, E. J. Petroff, R. J. Powell, of Atlantic City; Thomas F. Durham and Frank Reeder, of Philadelphia. The company has rights to build a line across the Meadow turnpike and through Pleasantville and Absecon.

SCHENECTADY, N. Y.—The mayor has signed the ordinance granting the Schenectady Street Railway Company permission to extend its lines through Lafayette Street and Park Place to Nott Street.

SYRACUSE, N. Y.—Two cars of the Syracuse, Lakeside & Baldwinsville Railway Company collided head-on just outside of the city limits Aug. 8. Nine passengers were injured.

BUFFALO, N. Y.—President Ely, of the International Traction Company, has notified the Mayor that his request for the lowering of the steps of the one hundred new open cars placed in operation by the company this season will be complied with. President Ely asks that the citizens bear with the inconvenience until the advent of the winter cars, as it is impossible to make the necessary changes until new trucks have been placed under the cars. It will require several months to manufacture the new trucks.

BROOKLYN, N. Y.—A man who recently tried to stop a car here by placing a large cobblestone on the track of the Third Avenue line of the B. R. T. was fined $10. There was a delay on the road, and several cars darted past him regardless of his cries and shouts to stop. In mad desperation he placed the stone on the track, feeling sure that the motorman of the next car would have to stop and remove the stone before proceeding, and knowing that while this was being done he would have an opportunity to board the car. The man's name was obtained by the company, and he was promptly arrested.

BUFFALO, N. Y.—Arrangements are now completed for the opening of the Olcott extension of the Buffalo Railway Company on Aug. 29. The dedication of the new resort fitted up by the company at a cost of $75,000, will take place on the date of the great Niagara County farmers' picnic. The Olcott branch from Lockport passes through one of the greatest fruit-growing sections of the State. Officials of the road believe that Olcott will become one of the most popular resorts on Lake Ontario. The bathing beach is one of the finest to be found anywhere. A fine park has been fitted up, a large casino built and every provision made for the accommodation and pleasure of the thousands who will be attracted there by the delightful ride and the beauties of the place. A regular round trip fare from Buffalo of $1 has been decided upon, with special rates of 75 cents on Saturday and Sunday.

LANCASTER, OHIO.—The Lancaster Traction Company has laid off its conductors. Citizens threaten to test the State law passed last year requiring two men on each car.

STEUBENVILLE, OHIO.—The Steubenville, Mingoe & Ohio Valley Traction Company has decided to enter the lighting field, and is soliciting contracts for lighting and furnishing power. A franchise will be asked for if enough business can be secured.

TOLEDO, OHIO.—Ten people were injured in a street car accident here a few nights ago.

TOLEDO, OHIO.—The employees of the power house of the Toledo Traction Company, under the leadership of Superintendent O. E. Olson, gave a trolley party in the company's special car last week. N. E. Wood, of the General Electric Company, Schenectady, was the guest of the evening.

OKLAHOMA CITY, O. T.—The City Council and the Oklahoma City Land & Electric Railway Company, who have been at loggerheads for some time over a franchise grant, have reached an understanding, and a franchise has been granted by the Council which is acceptable to the company. One of the provisions of the ordinance is that the company has cars running on three lines within six months. The officers of the company are: J. M. Lindsay, of Gainesville, Texas, president; S. H. Baird, vice-president; G. R. Stone, secretary; J. H. Everest, general attorney, and George C. Kelly, of Oklahoma City, general manager.

PHILADELPHIA, PA.—The Union Traction Company received this week the first of a lot of new type convertible cars ordered from the J. G. Brill Company. The cars have a number of new features connected with the convertible arrangements. They have cross seats and end entrances, however.

PITTSBURGH, PA.—The Union Planing Mill Company and others have filed suit against the Pittsburgh, Knoxville & St. Clair Street Railway Company and Henry Stamm, trustee, in which they ask for a rule on William J. Fawcett, receiver of the company and on the Pittsburgh & Birmingham Traction Company, to show why the property, franchises, stock and real estate of the Pittsburgh, Knoxville & St. Clair Street Railway Company should not be again offered at public sale. It is alleged that the Pittsburgh & Birmingham Traction Company failed to make good the terms of the previous sale, the paying of the receiver's certificates of petitioners being a part of the consideration of the purchase by the Pittsburgh & Birmingham Traction Company at the previous sale.

ASHLAND, PA.—The Borough Council has finally accepted an amendment to the ordinance granted the Ashland & Centralia Electric Railway Company in July, 1899, by which the company is permitted to use North Third Street on which to place a siding for the storage of cars, and to be used as a passing siding. Under the conditions upon which the permit is granted the text of the original ordinance, which requires the company to operate their cars to First and Centre Streets, is not changed. The cars will run to the crossing at First and Centre Streets, and after discharging or accepting passengers will then run back to Third Street, and if it is necessary, will run into the siding at Third Street and thus avoid the cars of the Schuylkill Traction Company which may be on the Centre Street line.

PHILADELPHIA, PA.—The oldest conductor in Philadelphia, in point of service, is dead. He was James S. Reeve, and entered the service of the Arch Street Railway Company in 1863. He has been successively engaged in the service up to a few days before his death.

PROVIDENCE, R. I.—The petition of the Rhode Island Suburban Railroad Company for a franchise in Bristol was granted August 6.

MILWAUKEE, WIS.—The Council committee on street lights has recommended that the Council grant the Milwaukee Electric Railway & Light Company a five years contract.

TACOMA, WASH.—Four of the officers and employees of the Tacoma Railway & Power Company have been arrested, charged with manslaughter in connection with the Fourth of July disaster, in which thirty-nine persons were killed and over sixty injured. The four arrested are: S. Z. Mitchell, general manager of the company; F. L. Dame, general superintendent; Charles Purdy, assistant superintendent; F. L. Boehm, motorman of the wrecked car. Bail has been fixed in each instance, and the date set for hearing the cases.

KINGSTON, ONT.—The annual convention of the Canadian Electrical Association will be held here Aug. 29, 30 and 31. The programme has not yet been completed, but will include the following papers: 1. "Utilizing the Available Central Station Capacity." Prof. R. B. Owens, McGill University, Montreal. 2. "Use of Dynamo and Storage Battery in Telegraph Offices." W. J. Camp, C. P. R. telegraph office, Montreal. 3. "Power Factor as Affecting Operation and Investment, with Special Reference to Induction Motors and Enclosed Arc Lamps." F. H. Leonard, Jr., Montreal. 4. "Government Electrical Standards," O. Higman, Ottawa. 5. "Railway Subject: Giving Several Curves Showing the Average Power During a Day, and Maximum and Minimum Requirements for Power called for on the Quebec System." Mr. Blair, Quebec Railway & Lighting Company, Quebec. 6. "Rotary Converters." A. Gordon Grier and J. C. Hyde, Montreal. 7. "Conditions Affecting the Wave Form of Alternators." Prof. L. A. Herdt, McGill University, Montreal, Que. The City Council has made an appropriation for entertainment purposes, and granted the use of the City Council chamber for the sessions, also space in the City Hall for exhibits of electrical appliances, while the local electrical companies have agreed to furnish, free of charge, current and labor to exhibitors.

CONSTRUCTION NOTES

[Information regarding the building of new roads, enlargements of power plants, extensions, etc., will be much appreciated.]

BIRMINGHAM, ALA.—The Birmingham Railway & Electric Company is making a number of important additions and improvements to its system. A new line, 2 miles long, is being constructed to Owenton. Three blocks of new track are being constructed to connect the old steam line of the Highland Avenue and belt. This will give a new route to the residence portion of the city. The Avondale line was recently double-tracked from Avenue F and Twenty-Third Street to Twenty-Eighth Street and F. Now the grading is being done on the same line for a double track from Twenty-Third to Twentieth Street. The South Highland line has been torn up for some ten blocks, and the tracks are being relaid. A handsome new brick and iron round house and barn is about complete. This is 140 ft. x 100 ft. and is one of the most substantial buildings in the city.

MERIDEN, CONN.—The Meriden Electric Railroad Company contemplates making improvements at Hanover Park next season, which will cost $25,000. This season has proven a very successful one at the park, and the improvements to be made include the general overhauling of the entire grounds and the addition of many new attractions and novelties.

PENSACOLA, FLA.—President Northup, of the Pensacola Terminal & Railway Company has just returned from Baltimore, where he has been in consultation with the directors of the road in regard to the improvement of the system. It has been decided to rebuild and generally overhaul the entire system, and included in the improvements to be made are the overhauling of the lighting plant and system, the addition of new cars, the electrification of the dummy line and the general reconstruction of Palmetto Beach, which it is proposed to turn into a veritable Coney Island.

EAST ST. LOUIS, ILL.—The Venice, Granite City & East St. Louis Electric Railway Company has decided to extend its line. The line will run direct from Granite City to East St. Louis.

MITCHELL, IND.—An electric railway line is projected to connect Oolitie City, Bedford, Mitchell, Orleans, Paloi, West Baden and French Lick Springs.

PERU, IND.—The promoters of the Peru-Converse Electric Railway report that they have secured the right of way for the entire 22 miles except through Miami County, and a petition has been filed with the County Commissioners for a franchise to complete the route.

INDIANAPOLIS, IND.—The Indianapolis Street Railway Company has opened its line to Riverside Park.

INDIANAPOLIS, IND.—The Indianapolis Street Railway Company has selected a site for its new power house. When the new structure is completed, the company will abandon its present power house.

INDIANAPOLIS, IND.—The Indiana & Ohio Railroad is ready to build about 50 miles of electric railway, and will be glad to make the best contracts they can for the material to be used in the construction of the line. J. M. Gore is president of the company.

Test of the Albany & Hudson Third-Rail Lines

The first trip over the third-rail line of the Albany & Hudson Railway, of Hudson, N. Y., was made Aug. 20. Power for operating the road was received from the company's new waterpower plant at Stuyvesant Falls, and the test was satisfactory in every respect. It is said that a speed of 60 miles an hour was attained at times.

Cleveland Companies May Carry Freight

The law department of the city of Cleveland has handed down an opinion citing that the Cleveland City and Cleveland Electric Railway Companies have the right to handle cars of the suburban companies carrying freight. The law department further says that the city cannot prevent the handling of freight, nor regulate the matter, so long as the traffic is conducted within reasonable bounds. The law department looked into the question at the instigation of the Council.

Mr. Abel of Chicago Inspects the Brooklyn Rapid Transit System

Howard Abel, president of the Lake Street Elevated Railroad, of Chicago, has been in Brooklyn for a few days inspecting the Brooklyn Rapid Transit system. Mr. Abel's trip is similar to one made by President Rossiter, of the Brooklyn Rapid Transit Company, to Chicago a few months ago, and was made for the same purpose, viz.: To study the transportation difficulties of the city and the methods by which they are overcome, and possibly to add a suggestion or two.

More Religious Advertising in Street Cars

The patrons of the Westport electric line in Kansas City, Mo., were greeted on the morning of the 15th with a new advertising card, among the others displayed on the car, which read: "How many minutes a day do you give your God?" Their curiosity was at once aroused, and this card was the talk of the city for a number of days. All efforts to ascertain who had the card placed in the cars were unavailing, but it is intimated that it was placed there by a prominent merchant, who is very religious, and who insists that his name be kept unknown. Several months ago the advertisement of a Wilmington, Del., church was placed in the cars in that city, but so far as we know these are the only instances in which such cards have been displayed in street cars.

Canada's Electric Railways

Up to the close of 1899 there were 632 miles of electric railway in Canada, as compiled by the government statistician, with a total car mileage of 29,646,847. The total number of passengers carried was 104,033,659, or a ride per capita of 20 miles. The mileage and passengers carried show that for each mile run the electrics carried three and one-half passengers; compared with the previous year the number of passengers carried increased nearly 9,500,000, and the number of miles run over 1,000,000. The number of transfers given in Toronto, alone, was 10,500,000. The amount of paid-up capital invested in electric railways is $21,700,000. The steam railroads in 1899 carried 16,168,191 passengers, with a train mileage of 25,292,859, thus making an average of one and one-half passengers per mile. The electric car mileage is, therefore, 4,500,000 in excess of the passenger and mixed trains of the steam railroads. Together the Canadian steam and electric railways carried over 120,000,000 passengers, the proportion being thirteen by steam to eighty-seven by electricity.

Duluth and Superior Systems Consolidated

The consolidation of the Duluth Street Railway Company, of Duluth, Minn., and the Superior Rapid Transit Railway Company, of West Superior, Wis., has been completed. The new company will be known as the Duluth-Superior Traction Company, and is incorporated under the laws of Connecticut, with a capital stock of $5,000,000, divided into $1,500,000 preferred stock and $3,500,000 common stock. The new company controls all the street railway lines in both cities with a total mileage of 73. The consolidation was effected by the transfer of the property of the Superior Rapid Transit Railway Company to the Duluth Street Railway Company, which company has authorized an issue of $2,500,000 first mortgage and collateral trust 5 per cent thirty-year bonds, of which amount $500,000 are to be kept in the treasury for future improvements, etc. The holders of old first mortgage bonds of both companies were offered the opportunity of even exchange for the new bonds, and the large part of them have accepted the offer. The con-

solidated bonds upon the Duluth property were all deposited with Brown Bros. & Company, under an agreement to receive in exchange therefor 110 per cent in new preferred stock and ninety per cent in new common stock. The Central Trust Company is trustee under the mortgage securing the new bonds and also registrar of the stock. The Farmers Loan & Trust Company, of New York, is transfer agent for the stock. C. G. Goodrich, vice-president of the Twin City Rapid Transit Company, of Minneapolis, is president of the new company, and L. Mendenhall, president of the Duluth Street Railway Company, is secretary and treasurer of the new company.

Convention of the Canadian Electrical Association

The tenth convention of the Canadian Electrical Association will be held in Kingston, Ont., Aug. 29, 30 and 31. Every effort has been made by those in charge for the comfort of the delegates, and the city has been thrown open to them. The city officials have been very hospitable, and have made an appropriation for entertainment purposes and granted the use of the City Council chamber for the sessions; also space in the City Hall for the exhibit of electrical appliances. The convention will be opened on the 29th at 10 a. m., with a welcome speech by the Mayor, after which the president of the association will address the delegates. The usual routine business, such as the report of secretary-treasurer, reading of minutes, presentation and discussion of papers, will follow. Aug. 30 will be devoted to the consideration of the president's address, reading and discussion of papers, etc. Aug. 31 will be devoted to selecting a place for the next meeting, determining the date of such meeting, election of officers etc. Among the papers to be presented at the meeting are: "Utilizing the Available Central Station Capacity," by Prof. R. B. Owens, McGill University, Montreal; "Rotary Converters," by A. Gordon Grier and J. C. Hyde, Montreal; "Railway Subject, Giving Several Curves, Showing Up the Average Power During a Day, and Maximum and Minimum Requirement for Power Called for on the Quebec System," by Mr. Blair, Quebec Railway & Lighting Company, Quebec. The social features of the convention include a searchlight excursion among the Thousand Islands, tendered by the Mayor and citizens of Kingston; a banquet at the Hotel Frontenac, and a grand spectacular band concert, introducing an electrical musical fantasy of the Battle of Paardeberg, with electrical effects and fireworks.

Chemical Specifications for Rails

In a paper read at the recent annual meeting of the American Society of Civil Engineers held in London, Robert W. Hunt referred to the chemical specifications for rails, and said in part:

"The writer has gone on record so often as believing that in the absence of work at low heats, incident to the present method of making heavy-sectioned rails, it is important to increase the carbon with the section to as great an extent as the phosphorus present will permit, without incurring risk from breakage, that it seems unnecessary to repeat the arguments."

At the Atlanta meeting of the American Institute of Mining Engineers, in October, 1895, the writer presented a set of specifications for "Steel Rails of Heavy Sections Manufactured West of the Alleghenies." In accordance with these specifications thousands of tons have been made and used with satisfactory results. During the last two years the Western makers have declined to limit the phosphorus to less than 0.10 per cent, but, in fact, have been making steel with a fraction less than that amount—say 0.09 to 0.096 per cent. And he regrets to say that in many cases they insist that the amount of carbon shall be less than that which he has advocated. He believes, however, that gradually, higher carbon will prevail, and certainly has not had any cause to change his mind on the subject. His experience as a steel rail maker, and as an observer of the wear of steel rails of many sections and diverse chemical composition, leads him to advocate: First, work, after careful heating of the steel, and continued until its temperature has been much reduced. Second, that the carbon percentages shall be increased in proportion to the increase of rail section, the ultimate amount being, of necessity, limited by the contained percentage of phosphorus. In all cases he advocates the use of drop tests, on samples from each heat of steel.

At present many of the American railway engineers use the drop test, but none of them demands the static or tensile tests insisted upon by so many engineers of other countries; nor does the writer think there is any necessity for these latter. The chemical analyses and drop tests are all sufficient.

As a matter of record, the writer gives the chemical formulas contained in his specifications of 1895, in accordance with which, as stated thousands of tons of rails have been made and have given good results. And while at present the Western makers decline to limit their steel to 0.085 per cent phosphorus, the writer certainly sees no reason to decrease the carbon. In other words, so many rails have been made and proven safe with quite as much carbon as given in these specifications, and with 0.10 per cent phosphorus, that the writer does not think the former element should be made less, certainly not until the details of manufacture have been changed.

Sec. 8.—The carbon in the 70-lb. section shall not be below 0.43 per cent nor over 0.51 per cent. In the 75-lb. section, not less than 0.45 per cent nor over 0.53 per cent. In the 80-lb. section, not less than 0.48 per cent, nor over 0.56 per cent. In the 90-lb. section, not less than 0:55 per cent, nor over 0.63 per cent. In the 100-lb. section, not less than 0.62 per cent, nor over 0.70 per cent.

The phosphorus shall not exceed 0.085 per cent.

The silicion shall not be below 0.10 per cent.

The remainder of the chemical composition of the steel to be left to the maker's judgment.

Color Ordinances

Reference has been made in recent issues of this paper to the ordinances existing in certain Southern cities as to separate accommodations for colored and white passengers. Below is given the text of an ordinance recently passed in Montgomery, which is a sample of those in other cities:

An Ordinance to Regulate the Transportation of Passengers on Street Railways of the City of Montgomery and Its Police Jurisdiction.

Section 1. Be it ordained by the City Council of Montgomery as follows: That all street railways operated in the city of Montgomery and its police jurisdiction shall provide separate accommodations for the white people and negroes on said street railways by requiring the conductor or other employee in charge of said car or cars to assign passengers to seats on the cars under their charge in such manner as to separate the white people from the negroes when there are both white people and negroes on the same car, except that negro nurses having in charge white children or sick or infirm white persons may be assigned seats among the white people.

Sec. 2. Be it further ordained: That all conductors and other employees while in charge of cars are hereby invested with the police power of a police officer of said city to carry out said provision, and any passenger refusing or failing to take a seat among those assigned to the race to which he belongs—if there is any such seat vacant—at request of conductor or employee in charge of said car, shall, upon conviction, be fined not more than $100.

Sec. 3. Be it further ordained: That all conductors and other employees superintendents of companies, and any officer, agent or employee who shall fail or refuse to provide for, and enforce such separation of the races as is herein provided upon the cars of said company operating in the city of Montgomery and its police jurisdiction, shall, upon conviction, be fined not more than $100 for each day they so fail to provide such separate accommodations.

Sec. 4. Be it further ordained: That nothing in this ordinance shall be construed as prohibiting the street railways from separating the races by means of separate cars or trailers on such lines as they may see fit.

Sec. 5. Be it further ordained: That this ordinance shall take effect immediately after its adoption.

Adopted Aug. 6, 1900. Approved Aug. 10, 1900.

E. B. Joseph, Mayor.

Street Cars in Glasgow

United States Consul Taylor at Glasgow makes the following report to the State Department regarding the street railway system of Glasgow:

"The street railway system of Glasgow is owned and operated by the city under the direct supervision of a committee of the City Council. The report for the year ended May 31, 1900, shows that the total length of double track operated by the city is 41 miles, 1 furlong, 178 yds. over 42 miles, 2 furlongs, 161 yds. of streets, making a total length of single track of 83 miles, 3 furlongs, 119 yds.

"The gross capital expenditures for the system since 1894 (independent of operating expenses) have been $5,164,975, and the present indebtedness is $4,061,806. The capital invested is $4,559,502. Of the 41 miles of double track, 5 miles have electric traction, the rest being operated by horses. The total receipts of the system during the year were $2,286,850. The working expenses were $1,676,412, leaving a balance of $610,438, of which there was expended some $84,000 for interest on capital, $57,501 for sinking fund, $156,096 for depreciation written off capital, etc. One item of $60,000 consists of payments made to the general revenue fund

of the city, which is in lieu of the amount which the city would receive in taxes, it is presumed, were the system operated by a private company. The balance goes into the reserve fund.

"There are 3400 persons employed, including 100 clerks. The general manager receives $6800; the chief engineer, $2400; the electrical engineer, $2000; and the mechanical engineer, who has charge of the power station, $1216. Switch boys receive 28 cents per day; trace boys, from 40 to 52 cents per day; car cleaners, from 88 cents to $1 per day; drivers, conductors and motormen, from $1 to $1.12 per day. These rates apply to Sundays and week days alike.

"The rolling stock consists of 384 horse cars, 132 electric cars (47 only of which are now running), 17 omnibuses, 39 lorries, and numerous carts, wagons and vans. There are 4411 horses.

"Work is now progressing, with the object of changing the entire system to electric traction, which it is hoped to have completed within the next eighteen months. No underground conduits will be used, according to the present plans. Fares range from 1 cent for first half mile to 2 cents for a mile; the longest ride is 6 miles, costing 6 cents. No transfers are issued, and tickets are not used.

"The committee of the City Council having supervision of the tramways receives no compensation. For that matter, however, no member of the city government of Glasgow, including lord provost, town councilors and bailies (police judges), receives compensation. The city of Glasgow has a population of about 850,000 and spreads over an area of nearly 12,000 acres.

"There are no electric or other tramways extending out of Glasgow to other towns or cities. Within the city is an underground cable road which makes a circuit of about 5 miles and is owned and operated by a private company. The rate of fares on this road is about the same as that prevailing on the surface roads."

Trolley, Steam and Third Rail in Connecticut

An article appearing under this caption in a recent issue of the *Railroad Gazette* enumerates the methods adopted by one steam railroad—the New York, New Haven & Hartford—to choke trolley competition. This company early realized that the introduction of the trolley meant reduced earnings, and at once set out to oppose all trolley projects. Its opposition began in the State Legislature, where every effort was made to squash the project. If, however, the road was finally built, the policy of the company was to buy it outright. We give the main part of the paper here, as it will undoubtedly interest those of our readers who have met with opposition in the projection of a system entering a steam railroad territory:

"In the sharp conflicts of the New York, New Haven & Hartford (Consolidated) Railroad Company with the promoters of parallel trolley enterprises, the efforts of the great steam corporation were largely centered against the interurban trolley projects. So successful had its resistance been that up to a few years ago, out of eighteen cities in the State only four were connected by trolley lines, and those from cities in two cases so contiguous that they formed, in effect, single municipalities. The change during the last four years, and particularly during the last two, is significant. Now, out of the eighteen cities in the State containing about 65 per cent of the whole population of Connecticut, twelve have trolley connection with other cities. Six cities—Waterbury, Meriden, Danbury, Middletown, Willimantic and Putnam—are still segregated, and one of them, Willimantic, has, as yet, no local trolley system. Of the six segregated cities, moreover, Middletown is pushing for trolley connection with Hartford; Meriden for connection with Middletown, Waterbury and New Haven, and a more important enterprise looks to the extension to Waterbury of the trolley system of the lower Naugatuck Valley. Within a year the tracks of the Bridgeport Traction Company have been extended to Shelton and, practically, to the cities of Ansonia and Derby, while the Norwich-New London trolley parallel, the cause of a long and picturesque contest reaching over several years, has just been opened for traffic. A few years more must undoubtedly find the interurban trolley system of the State complete, so far, at least, as to leave no segregated cities. It has already advanced so far and at such a pace as to create a new situation and give rise to some suggestive problems in future rivalries of steam and trolley.

"In meeting these interurban extensions the Consolidated Company has not been idle. Some of them, including one or two of the most serious, the steam company is still blocking in the State Legislature. The third rail has been used thus far only on the Highland division from Hartford to Bristol, a distance of about 17 miles. In one case, the connection between Bridgeport and New Haven, the Consolidated Company allowed the connecting trolley line to be built, relying on the crookedness and indirection of the route between the two cities. But its immediate policy is evidently the renewal of its old plan of 'breaking' parallels by out and out purchase of trolley roads—illustrated within a few months by its reported and presumptive purchase of the Greenwich system and of the People's Tramway, of Killingly—the latter purchase not publicly announced, but well assured, and of such a nature as to deserve its paragraphic description.

"The People's Tramway Company began as a distinctively parallel enterprise looking to both passenger and freight competition with the Norwich & Worcester division of the Consolidated, essentially a freight division with low grades. The trolley charter was a liberal one, giving rights to build 31 miles of track, reaching eleven places, with 23,000 inhabitants, and to build to the northern Connecticut State line, connecting with a Massachusetts trolley system reaching south from Worcester. As a whole, it threatened a complete parallelism from Norwich to Worcester with freight carrying as an important, if not primary, object. To avert the danger the Consolidated Company has bought out the whole enterprise; it is building a dam to supply a great waterpower to furnish motive power for the trolley, and light for the communities reached by its wires; it proposes, if necessary, to build to the State line to preserve its own territory; and freight service to the steam railroad stations on lateral trolley lines forms an important part of its plan, the seemingly paradoxical feature of which is a steam company's paralleling itself by trolley for the sake of controlling territory and preserving its own traffic. The results of this novel and homeopathic device, on a pretty large scale, of meeting trolley rivalry, will be most instructive, but will not, of course, be evident for some years to come. Meanwhile the Consolidated Company, at uncertain cost, certainly 'protects' its Norwich & Worcester division.

"The consolidation of Connecticut trolley systems has gone on swiftly and surely, and at an accelerating pace. At the opening of the year 1893 there were 147 miles of street railway in the State. There are now about 490 miles. They are represented nominally on the schedules of the State Railroad Commission by thirty-one companies, but these, by consolidation, have, in fact, been reduced to sixteen companies. Of the 490 miles of trolley track in the State about 130 miles are owned or controlled by the so-called 'Young Syndicate,' commonly regarded as identical with the United Gas Improvement Company, of Philadelphia; about 90 miles by the Fair Haven & Westville Company, and about 62 miles by the Hartford Street Railway Corporation, making 282 miles, or somewhat more than 57 per cent of the Connecticut mileage controlled by three interests. The Consolidated Company owns a trolley trackage of about 42 miles, which would give about 66 per cent of the trolleys of the State now controlled by four interests, and a far larger percentage were the values of the four trolley interests to be reckoned; and consolidation still goes rapidly on, carrying with it, in not a few cases, lighting plants and functions also.

"In the long rivalries of electricity with steam in the State this merger of electric interests betokens new conflicts and new conquests. The steam corporation must hereafter meet in the Legislature not scattered and divergent trolley forces, but centralized ones, backed, in some cases, by exotic capital, and powerful whether considered individually or apart. At least one of the large trolley combinations may be set down as very aggressive, planning extensions, some of them parallels, and almost necessarily relying in part on such extensions, together with possible freight and express business for returns on the large prices paid for acquired roads. Small economies in operation, blanket mortgages and stock bonuses hardly supply an intelligent motive in the trolley mergers. Ulterior aims which menace steam-railroad interests and imply new contests may reasonably be looked for."

Taxation in Ohio

The Ohio State Board of Commerce, of which E. M. Thresher, of Dayton, is president; C. B. Murray, of Cincinnati, is general vice-president; C. D. Firestone, of Columbus, is treasurer, and Henry A. Griffin, of Cleveland, is secretary, has issued the following circular:

August 1, 1900.

To the Citizens and Business Men of Ohio:

GENTLEMEN.—A widely disseminated discussion of clearly defined propositions is an indispensable preparation for the enactment by the State Legislature of measures to promote efficient government and safeguard the interests of taxpayers.

The people should derive benefits from government of greater value than its cost. When taxation is kept within such a limit and is so laid as to produce this result, it promotes prosperity. When

it exceeds this normal limit, or is not justly laid, it is oppressive.

No State has succeeded in devising a satisfactory system of taxation. Ohio can do so and become an example for others.

Legislation affecting municipal affairs absorbs fully 75 per cent of the time of the Legislature. Municipal debts and taxation are increasing at an alarming rate. The relations between municipalities, the people and public service corporations are not satisfactory. During every session of the Legislature attempts are made to enact measures on these subjects that are not properly drawn.

As a means of continuing its work upon these subjects and to secure a popular and wisely guided discussion of them, the Ohio State Board of Commerce has arranged to use the columns of *Public Policy* for an open discussion of the propositions following:

1. The objects of taxation for State, county or local purposes should be separated so that assessments shall affect only the tax district for which they are made.

2. Taxation for unnecessary purposes, and to provide funds to cover waste and extravagance, can be prevented by a needed administrative inspection and publicity.

3. Efficiency and economy in the administration of public business can be developed and maintained only by a uniform system of accounting, prescribed and audited by the State, and the publication of annual comparative statistics.

4. Deficiencies to be paid by taxpayers, in the case of publicly owned and operated industries, should be prohibited by providing that service rendered shall not be sold to private or other users at less than its true and entire cost.

5. Public mortgages on taxpayers' property for the purpose of acquiring and operating public service industries should be prohibited. Bonds authorized for such purposes should be secured only by mortgage on the use of all public rights of way used by, the property acquired for, and the revenue derived from, the industry, without recourse upon funds raised by taxation.

6. Corporations owning and operating public service industries should be regulated by contracts between them and the local or the State government, for an exclusive supply of the service they are to render for private and public use. Such contracts should provide that the price to be charged for the service should cover only cost plus a reasonable profit on actual investment, and stipulate that all accounts of the contracting corporation necessary to the determination of cost shall be kept in form prescribed by and audited by the State.

7. Efficiency in office is the true test for public employees. Merit shown by service record should be the means for retaining employment and winning promotion, to the exclusion of all other influences.

8. Self-government for every village and city should be secured by a general law providing for their uniform organization under municipal constitutions of their own adoption.

To make certain the enactment of laws in conformity with these propositions, by the next Legislature, one hundred or more persons in each legislative district should be in touch with the discussion of these subjects, for his own information, and to enable him to influence others. This will secure a uniform presentation of these subjects throughout the State. It will educate constituents and representatives to the same views, and will render the enactment of the legislation desired certain.

No fund is necessary for this purpose. The only requirement is that the citizens and business men of each district shall provide for their own district. When this is completely done the whole State will be cared for.

Unintelligent legislation costs much more than the educational work necessary to secure correct legislation. This is a perfectly sound proposition. We therefore believe every citizen and business man can better afford to pay $2 for a weekly, high-class journal, pledged to publish all this board may require, and one well equipped to guide the discussion intelligently, than not to have the work done.

For this purpose and upon this basis your co-operation is requested.

The Ohio State Board of Commerce,
(Signed) E. M. Thresher, President.
(Signed) Henry A. Griffin, Secretary.

Awards to American Exhibitors at Paris

On Aug. 17 the French officials announced the list of awards to American exhibitors at the Paris Exposition. Every line of industry and art received recognition, and, in all, the United States secured 1981 awards. Of these 220 were grand prizes, 486 gold medals, 583 silver medals, 422 bronze medals, 270 honorable mentions, and a long list of gold, silver and bronze medals for collaborators.

Below are given a list of the principal exhibitors, as given out to date, in the departments of machinery and transportation, who received grand prizes or gold medals:

DEPARTMENT OF MACHINERY—GROUP IV.

GRAND PRIZES

Worthington Pumping Engine Company.
Batcheller Pneumatic Tube Company.
Brown & Sharpe Manufacturing Company.
Pratt & Whitney Company.
E. W. Bliss Company.
Niles Tool Works Company.
J. A. Fay & Egan Company.

GOLD MEDALS

Ball Engine Company.
William Sellers Company.
George F. Blake Manufacturing Company.
Tinius, Olsen & Company.
Otis Elevator Company.
Rand Drill Company.
Charles A. Schieren & Company.
Crane Company.
Ingersoll-Sergeant Drill Company.
Shaw Electric Crane Company.
Simonds Manufacturing Company.
Chicago Pneumatic Tool Company.
Morse Twist Drill & Machine Company.
Cincinnati Milling Machine Company.
Hendy Machine Company.
Warner & Swasey.
Norton Emery Wheel Company.
Bement-Miles Company.
E. C. Atkins & Company.
Gisholt Machine Company.
Jones & Lamson Machine Company.
F. E. Reed Company.
Deering Harvester Company.
Bullard Tool Company.
Pond Machine Tool Company.

DEPARTMENT OF MACHINERY—GROUP V.

GRAND PRIZES

American Steel & Wire Company.
E. C. Acheson.
Rowland Telegraphic Company.
Western Electric Company.
John A. Roebling's Sons Company.

GOLD MEDALS

Bullock Electric Manufacturing Company.
Lorain Steel Company.
Western Electric Company.
Alvin Manufacturing Company.
National Carbon Company.
Tiffany Glass & Decorating Company.
C. J. Toerring Company.
Ward Leonard & Company.
Helios-Upton Company.
Holophane Glass Company.
Hart & Hegeman Manufacturing Company.
Edison Phonograph Company.
Western Electrical Instrument Company.
Mica Insulator Company.

DEPARTMENT OF CIVIL ENGINEERING AND TRANSPORTATION

Phœnix Bridge Company.
Boston Transit Commission.
Baldwin Locomotive Works.
Pressed Steel Car Company.
J. B. Brill Company.
Westinghouse Air Brake Company.
Standard Electric Company, of California.
American Steel & Wire Company.
The New York Air Brake Company.

Annual Report of the Brooklyn Rapid Transit

The annual report of the Brooklyn Rapid Transit Company for the year ending June 30, which has been awaited with so much expectation in financial circles, was made public Aug. 17. It was officially designated a "Preliminary comparative statement of the

Brooklyn Rapid Transit and constituent companies for years ending June 30, 1899, and June 30, 1900," and shows on a basis of the surplus of $526,772 reported for the year's operation, about 1.17 per cent applicable to dividends on the company's $45,000,000 of stock. The report in detail shows:

Receipts	1899	1900
Passengers	$10,793,984	$11,206,716
Freight, mail and express	36,791	61,305
Advertising	109,487	108,783
Rents	140,811	167,253
Other miscellaneous income	234,960	224,493
	$11,316,033	$11,768,550
Expenses		
Maintenance of way	$374,947	$415,729
Maintenance of equipment	983,216	882,183
Operation of power plant	948,749	964,665
Operation of cars	3,593,367	3,551,476
General expenses	582,175	494,530
Damages	738,837	797,790
Taxes	636,635	736,721
Net fixed charges	3,659,988	3,398,684
	$11,517,914	$11,241,778
Surplus or deficit	(D) $201,881	(S) $526,772
Surplus June 30, 1899		96,654
Total surplus, June 30, 1900		$623,426

The operations of the Kings County Elevated for June, July and August, 1900 and 1899, are not included in above, the company having been operated independently during that period.

The above figures include the full effect of the strike which occurred on July 16, 1899. The extent of injury thereby caused is partially shown by the figures for July, 1900, as compared with July, 1899, as follows:

July	1899	1900
Gross receipts	$976,801	$1,141,742
Expenses, including taxes	719,796	670,642
Net earnings	257,005	$471,100
Net fixed charges	294,351	293,642
Surplus or deficit	(D) $37,346	(S) $177,458

Militantly British

The large orders for tramway apparatus awarded in England during the last few years to American manufacturers have had a disturbing effect upon the manufacturers of that country. Occasionally this feeling finds expression, as is shown by the following editorial appearing in one of the English engineering magazines under the title of "British Municipal Supporters of Foreign Competition":

"We are truly at a loss in what language to place before our readers an act so unpatriotic on the part of the local authorities of a British municipality, that we should refuse absolutely to believe it to have been committed had we not before us in black and white the fullest proof in the form of a document signed by the Borough Engineer of Southend-on-Sea. That the ratepayers of that town can be aware of the way in which their municipal officers are spending the rates is not creditable, and we feel convinced that the truth will be a shock to them as great as it must be to every patriotic Englishman. At this very moment, when the technical, as well as the political, press of our country unanimously endeavors to stir up our manufacturers to make a firm stand against foreign competition, and in this very hour of earnest effort to rally British producers, the Corporation of Southend-on-Sea throws into the lap of our American competitors the funds which have been entrusted to it by the community which it has the honor of representing.

"Southend-on-Sea is in want, it seems, of certain truck and car equipment for an electric trolley line, and only a few weeks ago visitors to the Agricultural Hall in London had an opportunity of seeing that such material is obtainable in our country, at reasonable prices, from industrial concerns that are exclusively British, and which spend the money they receive in our own country, employing British brain and muscle and encouraging British manufactures. What more natural, therefore, than to offer to such firms an opportunity of competing for the supply of the material required by the above-named Corporation? This is so obvious that the local authorities of Southend-on-Sea realized that, by the merest rules of decency, they were obliged to ask these firms for tenders. It is one of our best known engineering firms whom we have to thank for handing over to us the document that was sent to them. On page one of the specifications, where the Corporation describes what motors are wanted, we read as follows: 'The equipment under this section *must* consist of the following apparatus and materials, inclusive of supply, delivery and fixing. Each car to be supplied with: Two *Thomson-Houston* G. E. 52 railway motors on ten double-deck cars; two *Thomson-Houston*

G. E. 58 railway motors on two bogie cars; two *Thomson-Houston* G. E. 800 railway motors on two single-deck cars,' etc. Why any British firm, excepting the British Thomson-Houston Company, should be invited to furnish the above-named motors is an absolute mystery, for the choice of Thomson-Houston manufactures in preference to others has obviously been made beforehand, and naturally these manufactures cannot be supplied cheaper by anybody else than the Thomson-Houston Company. Since, however, there is a *British* Thomson-Houston Company in existence, our readers will perhaps say that the selection, although it indicates favoritism, is at least not necessarily unpatriotic. Granted, so far; but let them read what follows on page two: 'The motors shall be of the *General Electric of America's* manufacture.' Here, then, we see that not the *British* Thomson-Houston Company is intended, but it is stated in so many words that no British makers need apply, not even such as are called British by courtesy, and that the goods *must* be of *American* manufacture. Again on page three, for instance, we find, with reference to 'Controllers,' that these also 'are to be of the series parallel type of the *General Electric of U. S. A.*' On page five, with regard to 'Trucks,' occurs the following stipulation: 'The twelve four-wheeled trucks shall be of *Brill* (21-E. type, with solid forged frame) or *Peckham extension manufacture*,' *i. e.*, American, and 'the four bogie trucks are to be *Brill* or *Peckham maximum traction trucks*,' while 'the *axles* are to be of open-hearth steel of *Pennsylvania Railroad* standard, quality and test.' On the next page, finally, we read that 'four bogie *Brill* or *Peckham maximum* trucks are to be provided for,' and so on throughout the whole document. To make *American* manufacture, in a British municipal enterprise, a *conditio sine qua non*, and to deprive British manufacturers of even a chance of competing, is an act on the part of the local authorities of Southend-on-Sea that the patriotic ratepayers of that town—and we trust that these form a vast majority—should chastise as a gross abuse of their confidence; but to send to British firms a copy of a document of this nature, under the pretext of inviting tenders, is an action that, in the name of these firms, we feel it our duty to stigmatize as a disgrace for all those responsible for it. We most earnestly hope that never again shall we have occasion to bring to public notice a breach of loyalty to British interests so flagrant as that committed by the Corporation of Southend-on-Sea."

Experiments With Electric Traction on Trunk Railways*

BY N. H. HEFT
(Chief of electrical department, New York, New Haven and Hartford Railroad Company)

To procure such data as would enable the writer to submit a report of value to the Congress, on the above subject-matter, a list of questions was sent to all the managements of main line railways, members of the Congress. Seventeen of them replied that no experiments with electric traction had been made on their lines. The New York, New Haven & Hartford Railroad Company, Pennsylvania Railroad Company, and the Baltimore & Ohio Railroad Company replied that they had made experiments with electric traction on their main line railways, and the detailed answers of these companies may be found in the appendix.

Experiments with electric traction on main lines of steam railroads in the United States were begun in the early part of the year 1895. The managers of steam railroads were forced to take up these experiments on their systems, owing to the great inroads made in their passenger receipts, due to competition of the electric street railways, which, in some localities, amounted to 80 per cent. These street railways brought a new factor into the transportation problem, and one with which the steam railroad managers were wholly inexperienced.

With their tracks laid in the public streets of cities and extending to suburban and even interurban districts over public highways and private right of way, and, owing to their close proximity to homes and places of business, with frequent service and cheap fares, they had demonstrated that such a system of transportation was much more attractive to the traveling public than the one furnished by the steam railroads, and not only seriously affected the regular passenger business of the steam railroads, but created a pleasure traffic wholly their own. This convinced the steam railroad managers that they must turn to electric traction in order to retain their passenger traffic and compete with the light railways.

Charles P. Clark, former president of the New York, New Haven & Hartford Railroad Company, was fully convinced, as early as 1891, as shown by his report of that year to the stockholders, that the only effective way of checking this competition was to equip the lines affected with electric traction. He advocated equipping a branch line to demonstrate what could be done with electric traction on a standard steam railroad with a standard steam railroad equipment operated under standard steam railroad rules. This makes him the pioneer in electric traction as applied to steam railroads.

The New Haven system differs from every other important railroad property in this country, (*a*) in the immense volume of its passenger traffic, (*b*) in the large percentage of passenger revenue to total revenue, (*c*) in the large percentage of local revenue to total passenger revenue, (*d*) in the density of population in the territory served by its lines and (*e*) in the small area of that territory as compared with the mileage of the system. The company carried nearly 61,000,000 passengers in the year ending June 30, 1898, and the revenue amounted to over $17,000,000 from its passenger department, equivalent to over 51 per cent of the revenue from all sources. The system provides regular transportation facilities for about 6,000,000 people, and the density of population in Massachusetts, Rhode Island and Connecticut, in which nearly all its mileage is located, is 260 inhabitants per square mile—greater than that of any other State or section in this country.

Within its territory are found the two great cities of New York and Boston, with rich suburban residential areas tributary to their business centers, five other important cities with suburbs, and no less than sixty-five independent cities and towns of greater or less importance for manufacturing or residential reasons.

Owing to the close proximity of the cities and towns in its territory, the New Haven system had been seriously affected by this competition. The gravity of the situation was such that, in November, 1894, the management of the New Haven Road authorized the introduction of electric traction on the Nantasket Beach branch, the first installation of electric traction on a standard steam railroad. This was completed May 20, 1895.

At this time the Pennsylvania Railroad Company felt the effects of similar competition, and in 1895 authorized President George B. Roberts to introduce electric traction on the Bordentown & Mount Holly branch of its Amboy division. This installation was completed in July of the same year.

In the same year the Baltimore & Ohio Railroad Company had completed its tunnel under the city of Baltimore, and, in order to avoid the objectionable smoke and gases inseparable from service with steam locomotives, they decided to introduce electric traction on their belt and tunnel lines in the city of Baltimore.

In considering the application of electric traction to main lines, railway managers are confronted with the following questions, to which the writer appends answers, based on the experience of various roads on which electric traction has been introduced:

Can electricity be substituted for steam as a motive power on main lines of steam railroads?

Yes. But the value of electric traction on main-line steam railroads is wholly dependent on the style of equipment, manner operated, location of power station, method of power distribution and train service, and distribution of population in territory covered.

Can a main line so equipped be operated under the same rules as govern on standard steam roads?

Yes. The New York, New Haven & Hartford Railroad Company is operating by electricity traction 6.95 miles of double track, overhead trolley, from Nantasket Junction to Pemberton, 11.51 miles of double track third rail from Braintree to Cohasset, 3 miles of double track third rail from Berlin to New Britain, 18.6 miles of single track third rail from Hartford to Bristol, and 8 miles of single track, overhead trolley, from Stamford to New Canaan.

The Pennsylvania Railroad Company is operating 8 miles of double track, overhead trolley, from Bordentown to Mt. Holly.

The Baltimore & Ohio Railroad Company is operating 4 miles of double track, overhead trolley, in the city of Baltimore.

All the lines named above are operated under the same rules as govern the operation of steam trains on the other portions of the systems.

(*a*) Schedule speed has been maintained during times of heavy travel and frequent service.

(*b*) Train service has been reliable, and to a certain extent trains have been able to make up time.

Can same weight of train be operated?

Yes. Trains of the same weight have been operated by the three following methods:

(*a*) By using specially designed locomotives, as is done by the Baltimore & Ohio. This method has the disadvantages of great concentration of weight on roadway, and low efficiency when operating light trains. Where the service is infrequent or largely of freight, or where it covers a section of main trunk line through

* Abstract of paper to be presented at the International Railway Congress, Paris, Sept. 20-29.

service, such as that on the Baltimore & Ohio Railroad, then this equipment is the most desirable.

(*b*) By equipping standard passenger coaches with motors on one or both trucks and using these cars as locomotives to haul passenger trains. This style of equipment is used on the Highland, Hartford and Plymouth divisions, and New Canaan branch of the New York, New Haven & Hartford Railroad Company; also on the Bordentown & Mount Holly branch, Amboy Division of the Pennsylvania Railroad Company. Where the service is frequent and light, schedule speed moderate and station intervals sufficient to allow trains to reach full acceleration it has been demonstrated that this service can be operated satisfactorily. The simplicity and low first cost make this equipment desirable for this service.

(*c*) By equipping all or part of the coaches with motors mounted on motor trucks and operating them in trains controlled from the first, or any of the motor cars, as is done on the Alley Elevated Railway in Chicago. Where the conditions of operation require the maintenance of high schedule speed with frequent stops the problem resolves itself into one of acceleration and braking. These conditions are found mostly on the elevated railways of our large cities.

Can existing train schedules be maintained?

Yes. The service operated by electric motors on the Nantasket Beach branch of the New York, New Haven & Hartford Railroad Company during the summer of 1897 was the fastest ever operated over this branch, and one that could not have been operated with steam locomotives, as was frequently demonstrated during that year. This service is shown by the following official schedule.

Comparative speed of steam and electric trains on the Nantasket Beach branch of the New York, New Haven & Hartford Railroad Company.

	Length of Line	No. of Stations	Schedule Time	Average Speed
Steam, 1894	6 95 miles.	10	25 to 35 minutes	16.7 to 11.9 M. P. H
Electric, 1897	6.95 —	16	21 —	19.8 M. P. H.

Can stations be added without loss of schedule speed?

Yes. (See Appendix.)

Can a train of a given weight be accelerated more rapidly?

Yes. Owing to the steady torque of electric motors, at least 15 per cent of the weight on drivers is available for starting effort.

The test of the Baltimore & Ohio electric locomotives, which weigh 96 tons each, have shown a draw-bar pull of 60,000 lbs. on a dry rail, corresponding to a traction coefficient of over 30 per cent. Tests on a steam freight locomotive with 146,000 lbs. on drivers show a maximum draw-bar pull of 30,000 lbs., corresponding to a traction coefficient of 20 per cent or two-thirds of that developed by the electric locomotives.

A standard combination coach on the Plymouth division of the New York, New Haven & Hartford Railroad Company, equipped with four motors of 175 hp each, aggregating 700 hp and weighing complete 50 tons, developed 12,000 lbs. with an overload on the motors of only 25 per cent. Allowing a starting effort of 300 lbs. per ton weight of train, such a car could accelerate to a speed of 30 miles per hour in ten seconds, or allowing 90 lbs. per ton weight of train, could accelerate a train 130 tons to a speed of 30 miles per hour in thirty seconds.

A train of individual coaches each completely equipped with motors on all axles, operated from one control, would give the maximum acceleration possible, *i. e.*, that of a single unit with 100 per cent of its weight on the drivers.

Can an effective system of brakes be applied?

Yes. The Pennsylvania Railroad Company uses the full Westinghouse air-brake equipment; the Baltimore & Ohio Railroad Company uses the Westinghouse; the New York, New Haven & Hartford Railroad Company uses the Westinghouse and the Christensen brake with satisfactory results.

How will the electric air compressor compare in reliability and economy with the steam air compressor?

The Westinghouse, General Electric Company and Christensen air compressors have all proved reliable and fully as economical. The compressor, when using motors under car bodies, is placed on the platform of the open, in the baggage compartment of the combination and suspended under the closed coach, thereby allowing the motor car to be operated either as a single car or as a locomotive for drawing trains.

Can trains be provided with equally satisfactory train signals?

Yes. Whistles of the same power are blown from the air-braking reservoirs, and have proved satisfactory. Locomotive bells or heavy gongs are placed on cars and rung either by foot or hand power.

Can motor cars be equipped with pilots and headlights, complying with the statutory rules and regulations governing railroads?

Yes. The pilots can be attached to truck or coach body. Both electric and oil headlights are used, and are satisfactory. The New York, New Haven & Hartford Company uses oil in place of electric lights, owing to the loss of current when passing over grade crossings, where the third-rail conductor is cut out.

Can trains be operated over third rail during snow and ice storms?

Yes. The operation of the third-rail section of the Highland division of the New York, New Haven & Hartford Railroad Company during the last two winters has proved that passenger coaches equipped as electric locomotives, with nose plows and brushes, can handle snow as efficiently as steam locomotives with plows. The third rail is kept clear of snow by steel brushes mounted on the trucks ahead of the contact shoes. Ice, which gathers on the third rail during sleet storms, has proved more difficult to handle. Experience on this same division has shown that the use of a zero oil sprinkled on the third rail from the trains prevents the ice from freezing to the rail, so that it can be removed by the stiff steel brushes.

How will cost of operation be affected by more frequent service of lighter trains?

The service on the Highland division of the New York, New Haven & Hartford Railroad Company is frequent, with light trains, while the service on the Berlin branch is not so frequent and with heavier trains. A fair answer to this question will be a comparison of the train miles run on each branch and the cost per train mile.

Daily train miles, Berlin branch = 66.
Daily train miles, Highland division = 737.
Cost per train mile, Berlin branch = 30.3 cents.
Cost per train mile, Highland division = 12.5 cents.

How will cost of operation be affected by the form of power transmission?

(a) By overhead or underground trolley?
(b) By simple or sectional third rail?
(c) By direct or alternating current?
(d) By static or rotary transformers?
(e) By direct or alternating current motors?

The local conditions govern the form of power transmission.

(*a*) The overhead trolley form has proved to cost more to install and maintain than the simple third rail, and to be less economical to operate. The first cost of the underground trolley and the difficulties encountered in draining make its use prohibitive on main railways.

(*b*) As the simple third rail, charged throughout its length, has been the only form in use on main lines, no data as to the economics of the sectional or safety third rail can be obtained.

(*c*) On main railways, where the distribution of power does not exceed a distance of 10 miles to 15 miles, the direct current has proved economical. In lines where power must be transmitted over a greater distance than 10 miles to 15 miles the alternating current should be used.

(*d*) When alternating-current motors can be designed to give a satisfactory starting torque, then alternating currents may be transmitted from the central stations through static transformers direct to the motors. At present transmission with alternating currents requires the use of rotary converters for conversion to direct current when delivered to the working conductors.

(*e*) When the development of the alternating-current motor shall enable it to compete with the direct current, then there will certainly be a large saving for transmission over long distances, and the equipping of main trunk lines will follow.

How will cost of motive power per train mile with motor cars compare with steam locomotives?

A comparison of the figures obtained from the operation of the several power stations, and from the performance sheets of steam locomotives of the New York, New Haven & Hartford Railroad Company, shows the cost of motive power per train mile to be as follows:

Steam locomotives = $0.19 to $0.24.
Highland division = $0.0604.
Nantasket Beach branch = $0.1441.
New Canaan branch = $0.0783.
Berlin branch = $0.1406.

The cost of electric motive power shown above includes the operation and maintenance of power stations, the maintenance of motors and other equipment on the cars, oil, grease and waste used on the cars, and the wages of the motormen who operate the cars. The cost of steam motive power includes fuel, oil and waste,

maintenance of locomotives and the wages paid the men who operate the locomotives.

How will cost of operation per train mile with motor cars compare with steam locomotives?

The total cost of operation per train mile with electric motor cars (excluding interest and depreciation) on the New York, New Haven & Hartford Railroad is as follows:

Berlin branch = $0.3032.
Highland division = $0.1255.
Nantasket Beach branch = $0.2925.
New Canaan branch = $0.1754.
Figures for operation with steam cannot be obtained.

How will cost of train labor compare?

Cost of train labor per train mile as shown from operation with electric traction on lines of the New York, New Haven & Hartford Railroad Company is as follows:

Train labor Berlin branch = .18.
Train labor Highland division = .027.
Train labor Nantasket Beach branch = .0829.
Train labor New Canaan branch = .063.
Train labor with steam, per train mile, about .12.

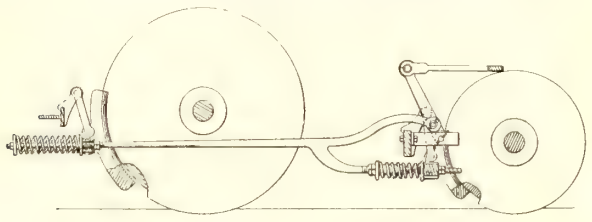
(To be Continued.)

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED AUG. 14, 1900

655,682. Car Seat; F. Bennett, New York, N. Y. App. filed Dec. 20, 1897. The back and seat are so connected through suitable levers that when the former is swung from one side to the other the seat will be shifted slightly in the opposite direction.

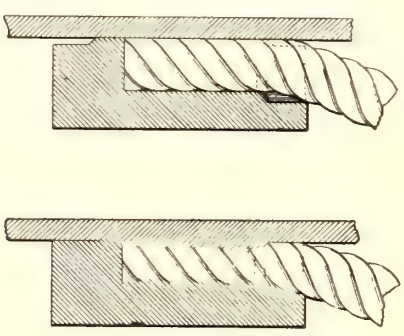


PATENT NO. 655,754

655,738. Car Spring; W. Robinson, Boston, Mass. App. filed Dec. 31, 1896. An arrangement of light and heavy springs intended to make the riding equally easy whether the load be light or heavy.

655,754. Differential Brake Mechanism; J. A. Brill and W. S. Adams, Philadelphia, Pa. App. filed March 3, 1897. This is a brake mechanism for applying different braking stresses to the large and small wheels of a truck having large driving wheels and small guiding wheels.

655,771. Car Seat; M. N. Forney, New York, N. Y. App. filed April 13, 1899. When the back is reversed, two oppositely located foot-rests are reversed at the same time.



PATENT NO. 656,125

655,839. Car Step; J. B. Thacher, Albany, N. Y. App. filed Oct. 20, 1899. Two steps are arranged so that the lower one must be entered by the passenger moving at right angles to the length of the car, while the next one is entered by moving parallel to the length of the car.

655,863. Sand-Box for Cars; A. W. Ham, Lansingberg, N. Y. App. filed Feb. 26, 1900. Two distributing spouts of different capacities, with mechanism for controlling each, are used.

656,030. Trolley for Electrically Driven Vehicles; L. Lombard-Gerin, Lyons, France. App. filed Jan. 9, 1900. An automotor-trolley, comprising an apparatus provided with a shaft having contact-rollers adapted to travel on conductors insulated one from another, the said apparatus having a motor possessing a fixed inductor and a movable armature, the periphery of which directly actuates friction-rollers on the shaft of the contact-rollers.

656,125. Bond for Track Rails; H. F. A. Kleinschmidt, Johnstown, Pa. App. filed Dec. 28, 1899. The end of the bond is placed in a groove in a metal block and then welded thereto.

656,133. Truck-Wheel and Armature Exchange for Street or Other Railway Cars; W. H. Cornner, Anderson, Ind. App. filed Nov. 23, 1899. A track passing over a pit is provided with a movable section arranged to be lowered and raised in the pit for the purpose of facilitating the mounting of parts of the car.

11,845. Reissue; Pneumatic Device for Clearing Railway Track Sanding Pipes; J. H. Hanlon, Boston, Mass. App. filed Sept. 19, 1899. Means are provided for directing a blast of air through the discharging nozzle of the sand-box, in order to clear it out.

PERSONAL MENTION

MR. E. G. LONG, of the Peckham Truck Company, has returned from a business trip to Europe.

MR. EVERARD HOLMES has been elected secretary and treasurer of the Interstate Consolidated Street Railway Company, with office at Pawtucket, R. I., to succeed Mr. E. R. Price, who resigned June 30.

MR. A. C. THOMPSON, of St. Louis, has been appointed superintendent of the St. Louis & Belleville Traction Company's lines between Belleville and East St. Louis, vice Mr. Thomas M. Sneed, who resigned several months ago.

MR. THOMAS NEELY has resigned as general superintendent and chief electrician of the Vicksburg, Miss., Railroad, Power & Manufacturing Company to accept a similar position with the Meridian Street Railway & Power Company, of Meridian, Miss.

NEWS NOTES

[*News notes for this department are solicited.*]

DENVER, COL.—The Denver City Tramway Company will make alterations and build an addition to the depot at Broadway and Alameda Avenue for the purpose of establishing a club room for the employees. A reading room and gymnasium has been established by the company in North Denver. The building on Broadway is 38 ft. x 50 ft. and is built of brick. The addition will cost $1000. Magazines and papers will be kept on file, and there will also be a small library.

HARTFORD, CONN.—The conductors and motormen of the Hartford Street Railway Company have been furnished with new cap medallions. Those for the conductors have black letters on a white ground and a border of gold. The motormen's medallions have white letters on a black ground and the border is of silver. The figures and background of each are of enameled leather. They are larger than the kind formerly in use and much more attractive. The employees deposit 75 cents with the company when they receive a medallion, and when they leave the service of the company they return the article and get their 75 cents back.

WASHINGTON, D. C.—There was a rear-end collision of two cars of the Great Falls line of the Washington Traction & Electric Company a few days ago. A number of passengers were slightly injured.

WASHINGTON, D. C.—About sixty new cars have been ordered by the Washington Traction & Electric Company. They will be unlike any now in use in that system. The body will be 28 ft. long, with cross seats. The window sills will be low, so that in summer the sashes can be lowered, with the effect of an open car, and in this way the same car can be available for all-the-year-round service.

ATLANTA, GA.—The lines of the Atlanta Railway & Power Company were tied up for two and one-half hours on Aug. 12. The suspension of traffic was caused by the burning out of an armature of one of the large machines in the company's plant and by the demolition of an overloaded engine which was making an effort to supply power to handle a sudden rush.

MUSCATINE, IA.—The Muscatine Electric Railway Company has submitted a proposition to the City Council offering to expend $100,000 in improving its property and extending the lighting and railway service provided the city will grant the company a ten years' extension of the lighting contract and a twenty-five year extension of the railway franchise. The company, if granted the desired franchises, will obligate itself to expend every dollar of the sum specified, the intention being to put in an entirely new power plant at a cost of $75,000, a new gas plant to cost $15,000, and two extensions of the electric railway line, and further agrees to erect a pavilion in Weed Park to cost between $4500 and $5000, with a seating capacity of 500, and adapted for use by dancing parties, comic operas, and summer attractions of various kinds.

Street Railway Journal

VOL. XVI. NEW YORK AND CHICAGO, SEPTEMBER 1, 1900. No. 35.

OPERATING METHODS OF THE COLUMBUS RAILWAY COMPANY

Columbus is practically the geographical center of Ohio; it is the greatest railroad center in the States, and is the State capital. Located here are the State House, the State penitentiary, institutions for the blind, insane and feeble-minded and deaf and dumb; there are also here United States barracks, accommodating 6000 soldiers. The city has a population of some 150,000 people, making it third in the State, and it includes within its corporation boundaries 16¼ square miles of territory. A large number of societies hold their conventions at Columbus, and, owing to its many attractions for the Ohio citizen, the number of excursionists who visit it throughout the year is very large.

VIEW ON HIGH STREET, SHOWING METHOD OF ARCH ILLUMINATION

The engraving on this page gives a view of one of the principal thoroughfares in the city, High Street, and also illustrates the ingenious and attractive method of illuminating the street by arches. These arches are placed at intervals along High Street from the Union passenger station to Livingston Avenue, a distance of about 7400 ft., being twenty-five in number. The spacing varies somewhat, according to the length of the different squares. The arches are supported upon the steel side poles of the railway company, the support beginning at a point about 16 ft. or 17 ft. above the pavement. The center of the arch is about 26 ft. above the roadway. Each span carries fifty 16-cp incandescent lamps, the receptacles for which are wired in a hood extending beneath the arch; this hood is painted white. The current is furnished by a local electric light company, payment for which is made up by an appropriation from the city of a certain sum, and subscriptions from the various property owners and store keepers along the street. The cost has been put very low, being $19 per month per arch. The lamps are lighted every night during the year. This is in addition to the regular arc lights. The weight of the arch proper, *i. e.*, the steel work, is ap-

proximately 1000 lbs., and the cost was about $150. This does not include the wiring and the lamps. This method of street illumination has been favorably commented upon by visitors to Columbus, and is one of which the residents along the streets feel justly proud. In another section of the city, called the "Hub," located in the vicinity of Fourth and Main Streets, this arch system of lighting is also used, but upon a smaller scale.

The Columbus Railway Company owns the entire street railway system, the lines of which radiate in all directions from the city's center with a total length of 98 miles. In addition to the city lines the company operates an interurban road from Columbus to Westerville.

The company, appreciating that street car riding is as much habit as necessity, encourages patronage in many ways. Visitors are informed by a sign at the entrance to the Union Railroad Station that a map of the city may be had for the asking. This is the street railway company's folder, and contains a map of the city, handsome views of the chief points of interest and comprehensive instructions for reaching them. Excursion trains are met by representatives of the company and these folders given out freely to all visitors. In this way some 60,000 have already been distributed this season. In addition to the folders the company publishes a handsome 52-page illustrated guide to the city and pleasure resorts, with map and street railway directions. These are mailed to Sunday schools, societies and others throughout the State, and assist in making up sight-seeing routes. The company believes that this advertising not only brings many people to Columbus who would not otherwise come, but by helping them to economize their time while in the city, results in their riding more often on the street cars.

To further encourage patronage, the company operates two pleasure parks. Olentangy Park has few equals in natural beauty. It contains 37 acres, and is cut across by numerous deep ravines, so shaded by overhanging trees that the sun rarely gets into them. Along one side of the park runs a branch of the Scioto River, affording splendid boating and delicious bathing. One of the most popular

features of the resort is the toboggan slide, which is a "shoot the chutes" on a small scale. Each bather rents his own toboggan, which he must himself carry up the incline. Added to the exciting ride down the incline is the pride of sliding furthest over the water before the toboggan sinks. Although the park is thick with trees, it is well lighted at night by a multitude of incandescent lights, even the river being illuminated throughout the length of the park. Disregarding the popular notion that people who have a chance to sit down do not spend their money, the park is everywhere furnished with comfortable benches. The most prominent of the buildings is the magnificent theater, whose spacious veranda, surrounded by a dense growth of trees, overhangs the Olentangy River 50 ft. below. The theater building is 80 ft. x 250 ft.; the auditorium is large, cool and comfortable, seating 2248 people. Ice water is supplied free from suitable tanks placed at convenient points through the grounds.

Minerva Park covers 150 acres. It is not so favorably located as Olentangy, but the same care is exercised to make it a popular and pleasant pleasure ground. It has bowling alleys, scenic railway, "shoot the chutes," etc., and a theater seating 2500 persons. This

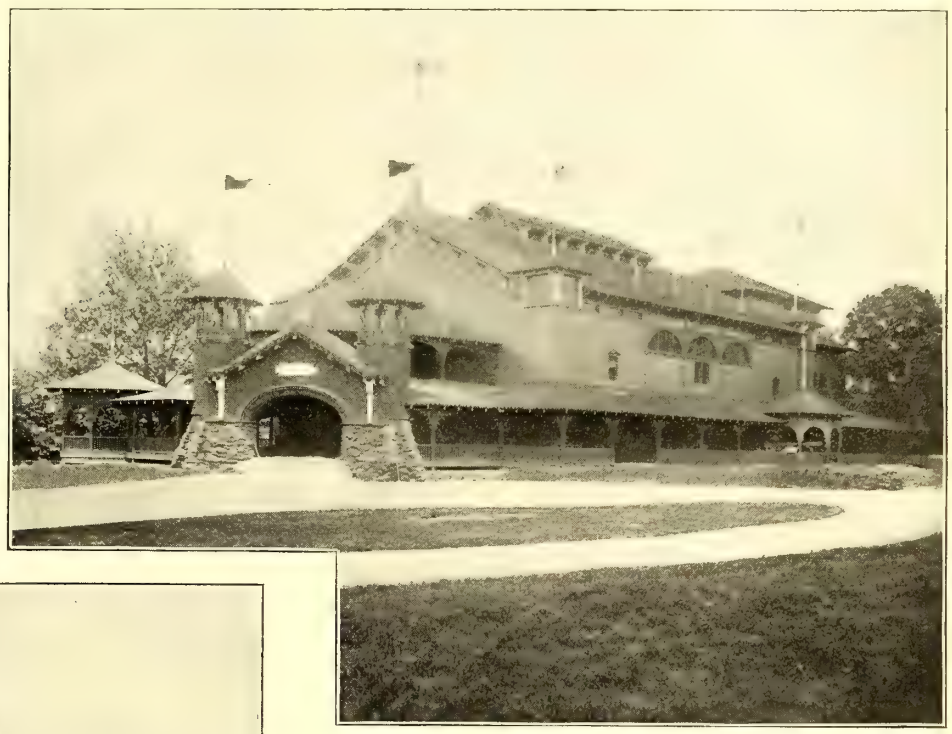
GATEWAY TO OLENTANGY PARK

park is forty minutes out from the city, a 15-cent fare for the round trip being charged, which includes admission.

The company's rolling stock is maintained in the best possible condition, with the fact in mind, as stated above, that many people ride for pleasure or from habit, and clean, comfortable, handsome cars go far toward increasing the road's receipts. The car equipment consists mainly of double-truck cars. Owing to the wide gage (5 ft. 2 ins.), the company uses the bicycle truck under all its double-truck cars. The standard box car is 28 ft. inside, with 4-ft. 6-in. platforms, the standard open car is 36 ft. over all, with twelve seats, and vestibuled. The company much prefers the vestibuled to the ordinary type of glass front. Following what is now very general practice, the company has party cars, which are rented by the hour or evening.

The repair shops are located in a large and well equipped building. Among devices of interest is a circular crane for handling trucks, motors, etc., and fully illustrated in the accompanying engraving. It is the intention of the company to equip this circular crane—as well as the car body hoisting trolleys—with compressed air hoists. Christensen direct-connected motor compresser and air hoists are to be used. A device for making armature coils is also shown. The reducing gear is for the purpose of giving a slow speed and avoiding any back lash.

The company has had excellent success in splicing cars. Twenty of these have been in service for four years, and



THEATER AT OLENTANGY PARK

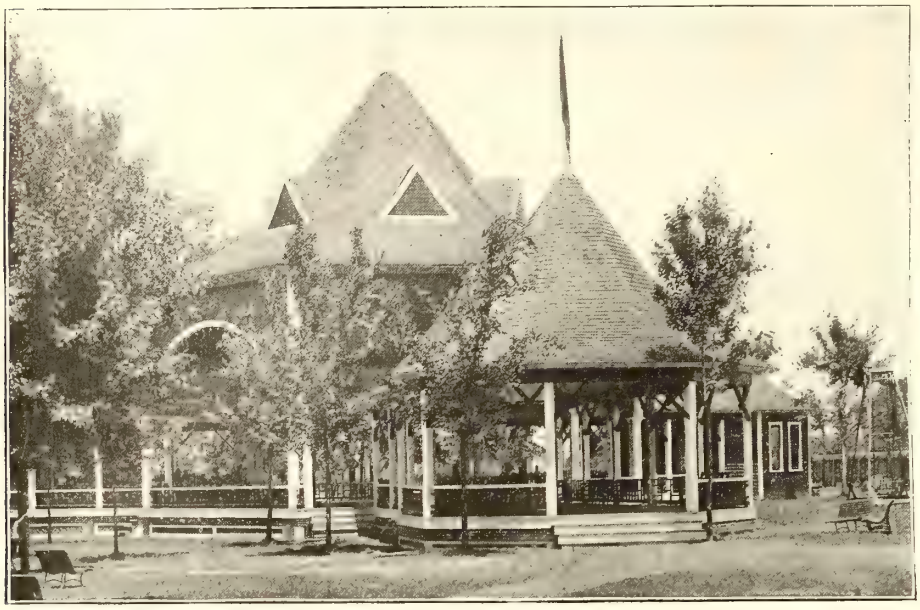
are apparently in as good condition as when the work was done. They are of special value, owing to their large carrying capacity and light weight. The spliced car bodies weigh a little over 9000 lbs., while new bodies of the same dimensions, which the company recently bought, weigh slightly over 14,000 lbs.; in other words, the spliced cars carry just as many people and weigh but little more when loaded than the new cars when empty. A working diagram is given, showing the general plan for splicing cars, with the arrangement of timber before covering over.

For use on interurban roads the company has spliced together two 22-ft. side seat combination cars, making a car body 42 ft. long. These cars were spliced in the same manner as shown in the accompanying plan, except that two 6-in. I-beams, filled in with oak on each side and running the full length of the car, have been added to provide for the heavy strain of interurban service. These cars have twenty-six seats upholstered in red plush, and seating fifty-two passengers. The cars are lighted by electricity and Pintsch gas. The company owns its own Pintsch gas plant, from which it supplies the gas to its interurban and private cars, and also to the steam railroad companies passing through the city, piping the gas from the plant to the Union Depot, about a mile away.

Another sketch shows the method of cleating wires under the side of the car in preference to using a cable the entire length. The wires are cleated, as shown, the full length of car underneath side seats, entering a cable at the ends which carries the wires under the platform to the con-

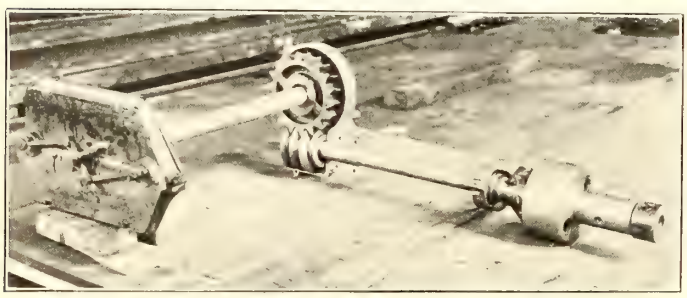
troller. All wires where passing through the floor or timbers of the car are protected by porcelain bushings. These porcelain bushings are considered a very important feature and have done much to increase the efficiency of the wiring. The total maintenance cost for all rolling stock is less than 1 cent per car mile.

Each car is fitted with an automatic fender, which costs, complete, $18. The company believes thoroughly in the use of fenders, and that they save many lives and serious accidents. One interesting case on record is that of a bicyclist who was struck by a car running at full speed. Both man and wheel were caught on the fender under the car, and when pulled out were unhurt, the man riding away on the wheel.

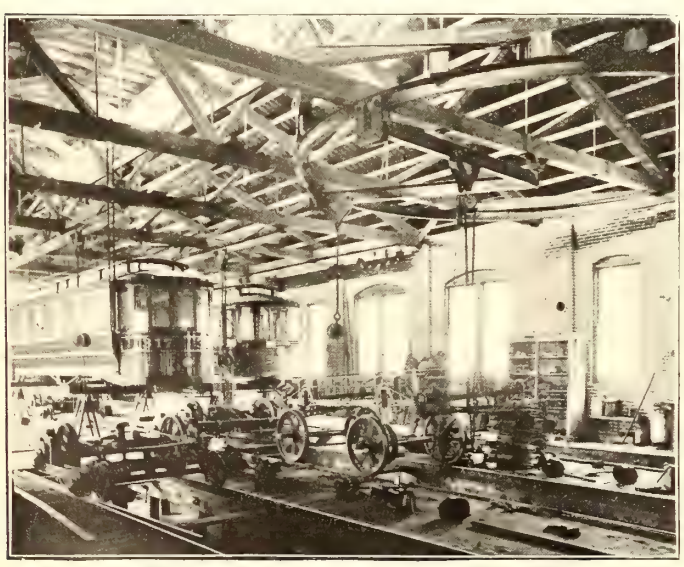


PAVILION IN MINERVA PARK

ENTRANCE TO MINERVA PARK

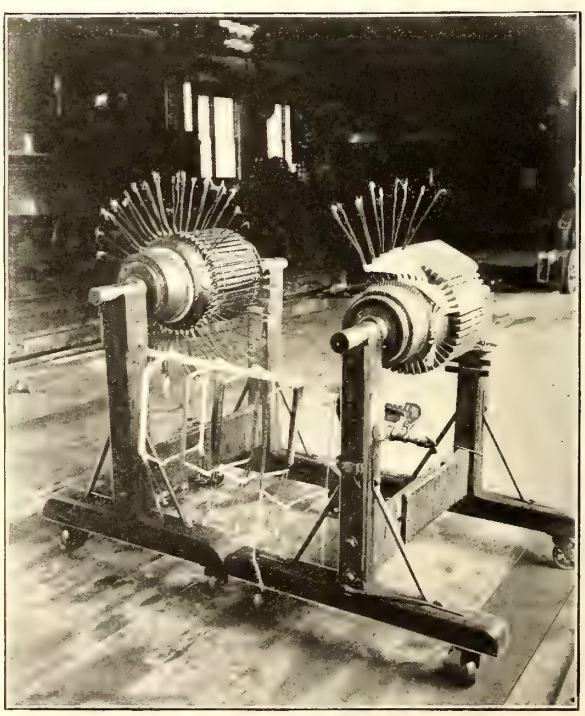


GEARING FOR WINDING ARMATURES



CIRCULAR CRANE IN ROSE AVENUE SHOPS

Trolley wheels, trolley harps and journal bearings are made in the company's own brass foundry. Trolley ears 14 ins. long cost 16½ cents apiece. Armature bearings have a composition of 80 per cent copper, 12 per cent lead, and 4 per cent each of phosphorus tin and pig tin, and show a life as high as three years. The journal bearings are bored in special design jig, which bolts on to the carriage of a lathe, using a boring bar with four cutters, viz.: A cutter at each end for facing the ends of brasses, a roughing cutter, which roughs out the work, and a finishing cutter, which sizes the brass. With this arrangement it is not necessary to caliper the brasses, except when setting the cutter; one setting of the finishing cutter will bore some-

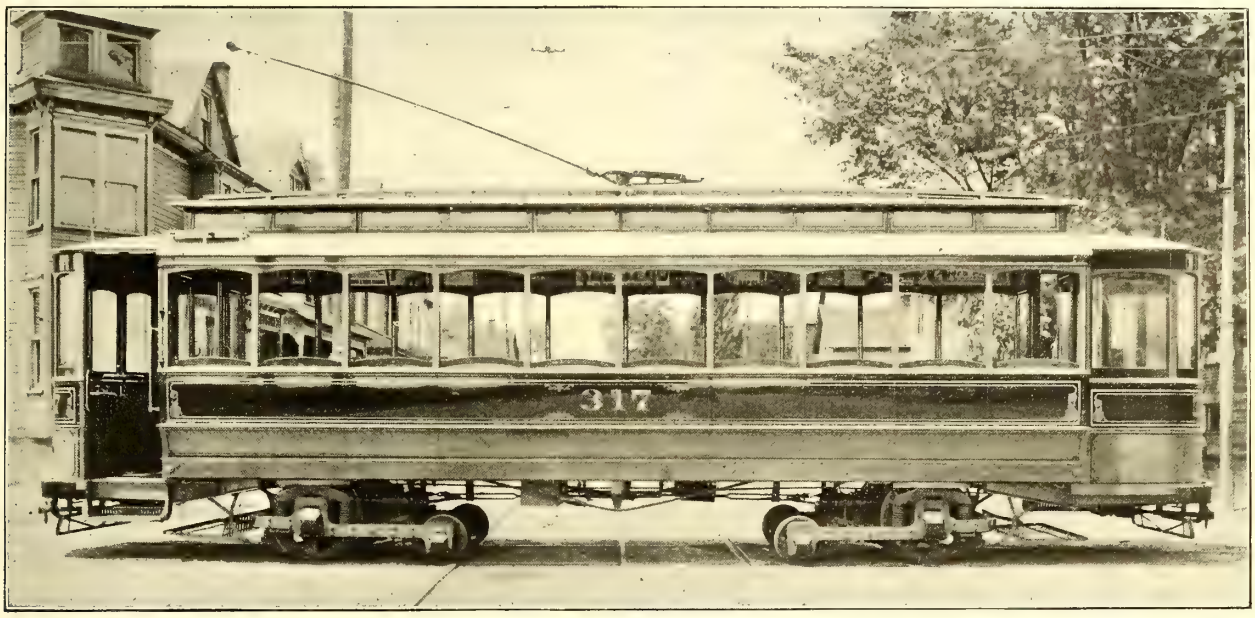


RACK FOR WINDING ARMATURES

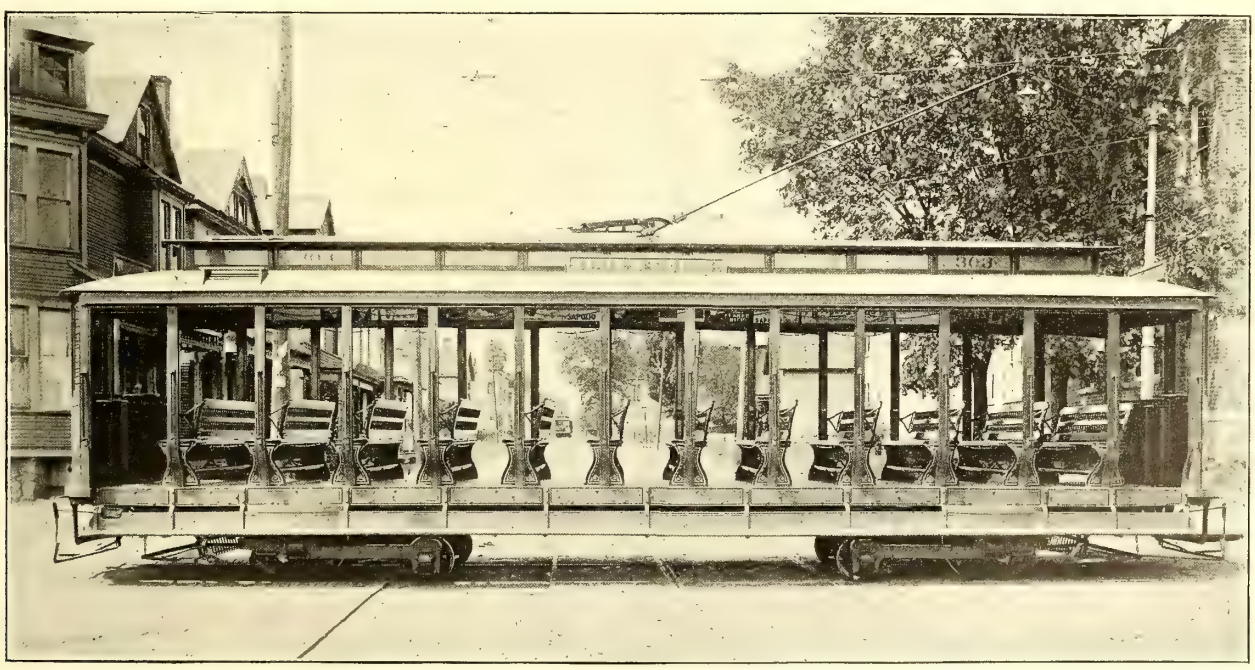
times as many as fifty bearings before needing sharpening.

The company's standard for new track and roadbed construction is 74-lb., 8-in. T-rail, laid on oak ties. The ties are laid on a bed of broken stone, which is also tamped in between up to within about 2 ins. of the tops of the ties. Then a layer of cheap concrete, flush with the tops of the ties. This is to keep the sand in which the paving blocks are imbedded from sifting down into interstices between the blocks of broken stone. This practice has greatly improved the quality and life of the pavement. The company paves to a foot outside of its rails. There are a large number of cast-welded joints on the system, and more will be put in this fall. They were put in by the Milwaukee Rail Joint & Welding Company, and the railway company itself, which now owns its own welding outfit. These joints have given excellent satisfaction.

In connection with the track work it should be stated that data relating to this department are kept in a very systematic manner. In general the idea is to get all the information which a manager would want in as concise a form as possible, and in a way which would require but a small amount of work to keep up. The record is divided into two sections: The first shows straight track, location of special work, kind of rail, pavement and joints; the second part is devoted to details of special work. Distances on straight track sheet are noted by 1000-ft. stations. Cross streets are not shown, only the exact location of the intersection of the cross street nearest each 1000-ft. station. Points of special work, curves, change of rail section and change of pavement, or a change in the kind of joints are noted in feet, counting from the preceding 1000-ft. station. In the special work record a sketch is made of each piece of work, noting joints and giving each frog and switch the same number as that in the original shop drawing from which the work was made. The connecting rails are also noted, so that special splice bars can be made at any time without disturbing the track until they are ready to be put on. Adjacent to each sketch is placed the name



STANDARD CLOSED CAR



STANDARD OPEN CAR

of the company by which the work was made, height of rail, original drawing number, weight of rail and maker's section number and the time work was laid. Renewals or repairs which were made to this work are also added as made. These records are all drawn on tracing cloth, from which blue prints are made once a year, and bound in a special binding made to fit the sheets; in this way the tracings are not handled at all, and form a permanent record.

METHOD OF SPLICING TWO 16-FT. BOX CARS

CAR MADE BY SPLICING TWO 16-FT. CARS

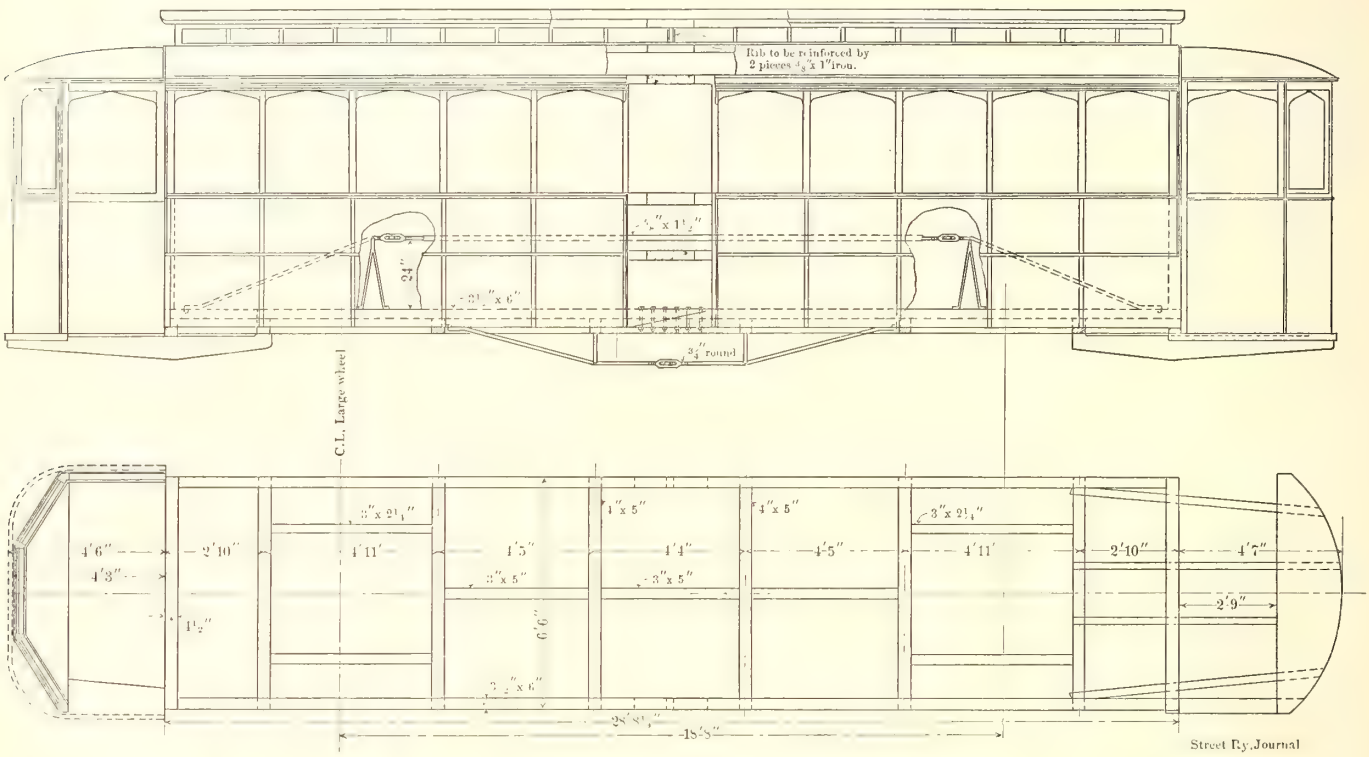


DIAGRAM SHOWING METHOD OF SPLICING CARS

Changes in this record are noted upon the tracing from track foreman's report. Once a year the entire record is very carefully gone over and verified.

On the Westerville interurban line is installed an interesting automatic signal, designed for use between

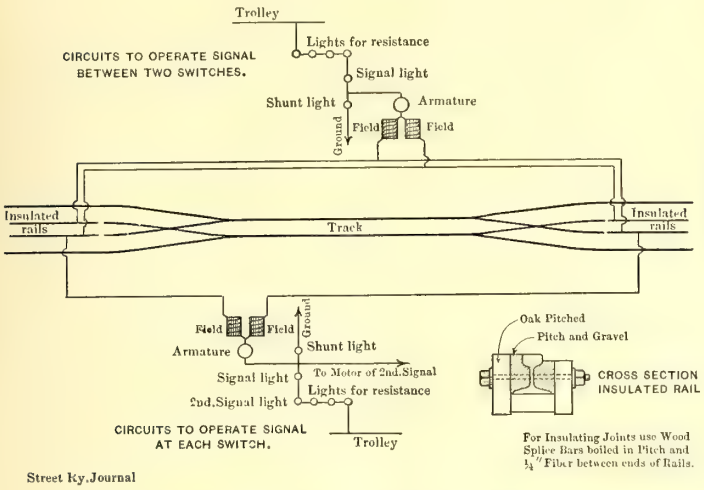

DIAGRAM SHOWING CONNECTIONS FOR SIGNAL

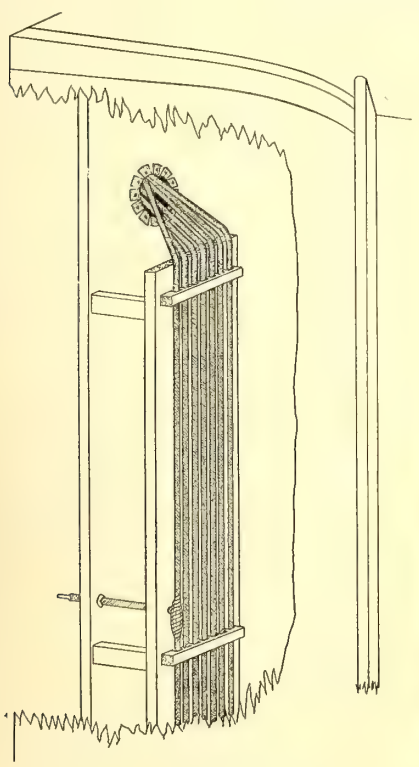
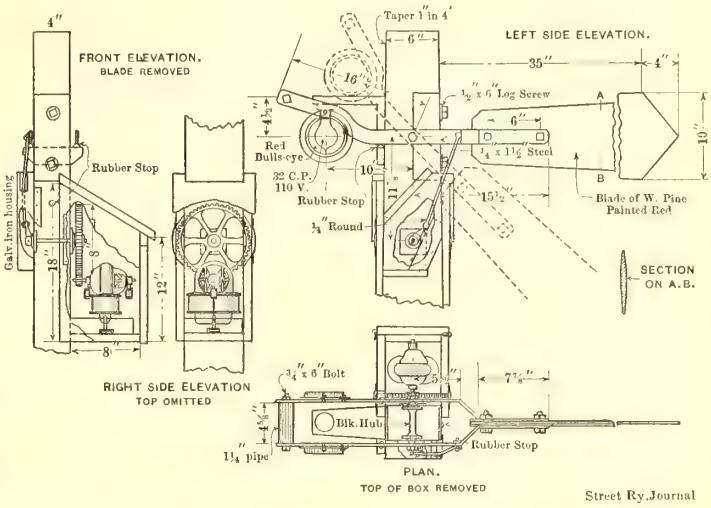
switches. This signal is thoroughly reliable, and a great assistance in the operation of the road. The design is somewhat crude, yet very substantial and positive. The signal arm is carried on the spindle of an ordinary bicycle wheel hub, the hub being securely fastened in the post, and the spindle to the side of the arm revolving in ball bearings on each end. This arrangement gives a very sensitive arm, and the side bearing prevents wind pressure from the side having any material effect upon its operation.



METHOD OF CAR WIRING

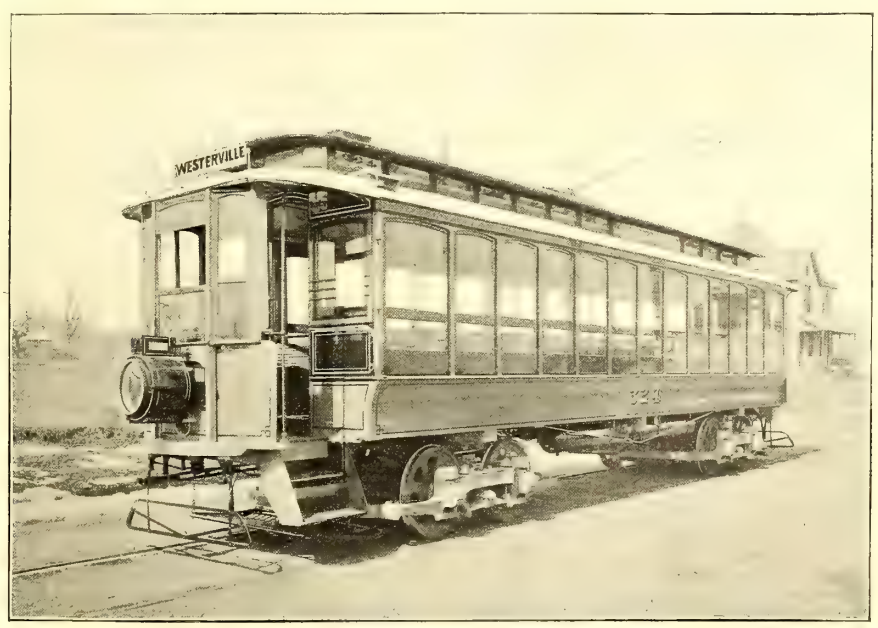
One end of the arm is made of white pine, painted red; the other end has two red bull's eye lights which cover or expose an incandescent light for night signal. The arm is operated by a Western Electric Company's 16-in. fan motor, geared to a countershaft, which is connected to the arm by a small crank and connecting rod. The crank is arranged to make a little more than half a revolution to throw the target from up to down. This signal forms a very simple locking device, and gives a maximum torque to start arm either up or down. The signal is operated by the wheels of the car passing on to an insulated rail, which rail is connected to the motor, axle



BLOCK SIGNAL

and car wheels, making the ground connections between insulated rail and ground. This circuit is clearly shown in the accompanying sketch. One field coil of the motor is used to throw target up and the other field coil so connected as to operate arm in other direction. The signal motor is shunted around a 50-volt lamp, which gives only 50 volts between insulated section of rail and the ground; in fact in actual practice the voltage is not even this high, as enough leakage will take place to reduce this voltage to about 30 volts, which is too low to be noticed by coming into contact with rail.

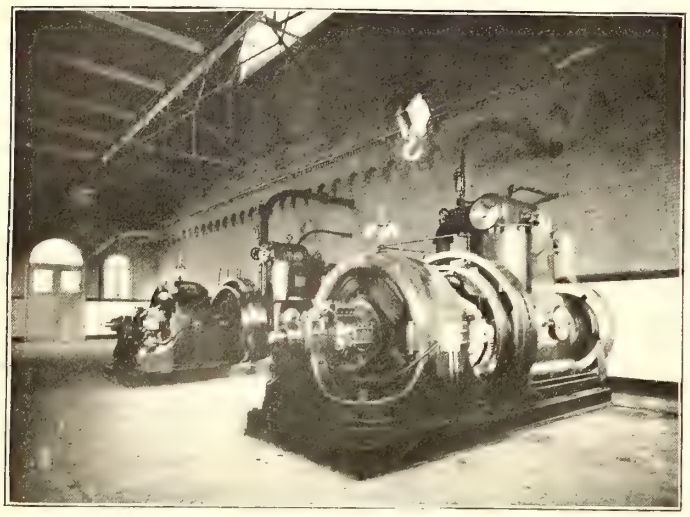
The company has two power houses, one of which was



INTERURBAN CAR ON WESTERVILLE LINE

acquired by purchase, and is used largely as an auxiliary. The first, the Spring Street station, has two Buckeye tandem compound-condensing engines of 750-hp each, direct-connected to G. E. 500-kw generators. This station has also one cross-compound Green-Wheelock engine of 1200 hp, direct connected to an 850-kw G. E. generator; three McIntosh & Seymour tandem compound engines of 300

hp each, belted to G. E. generators; Wheeler surface condenser, Cockran oil separator and Babcock & Wilcox boilers. There is also an automatic gravity oiling system, which was installed several years ago, and was one of the first in the State; the drips all run back to the oil room through a waste and sand filter, and from the storage tank

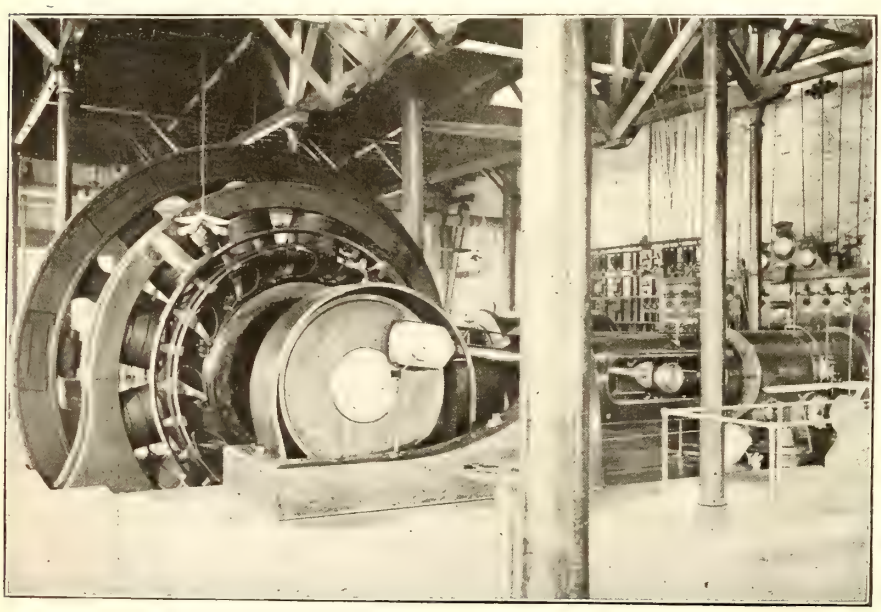


INTERIOR OF MILO POWER STATION

the oil is pumped back to the pressure tanks located in the engine room.

The Milo station is equipped with eight Stirling boilers, aggregating 2400 hp, Murphy furnaces, Green economizer and three Westinghouse engines, aggregating 1100 hp, direct-connected to Westinghouse generators. At this station there is installed a We Fu Go purifying system, which has given excellent satisfaction, having done away entirely with the necessity of cleaning the boilers.

The Columbus Railway Company has had no trouble



INTERIOR OF SPRING STREET POWER STATION

with its employees for many years. A graded schedule of wages for motormen and conductors is in force. For the first three months in the company's service the employee received 15¾ cents per hour; for the next nine months 16¼ cents per hour, and 17¼ cents per hour thereafter. Men who have been in the company's employ for six months are paid the same interest on their earnings for each six months as is paid on the preferred stock of the company. Men who have served for five years receive each year thereafter one free uniform, and as a mark of such service are allowed to wear a gold band upon the arm. After ten years of service another gold band is added on the arm and the company issues to the man without charge two uniforms per year. Fifty per cent of the company's men have one or more bands. The qualifications necessary to a successful application for the position of motorman or conductor are good health, good moral character, good eye sight without spectacles, hearing, heart and lungs sound, free use and movement of hands, arms and legs; age between twenty-three and forty years; must weigh not less than 150 lbs., if an applicant for conductor, or not less than 175 lbs., if applicant for position as motorman, and height must exceed 5 ft. 9 ins.

The Columbus Railway Company was incorporated in Aug. 18, 1889, and is a consolidation of the Columbus Street Railway Company, chartered April 25, 1892; the Crosstown Street Railway Company, chartered Feb. 24, 1893, and the Columbus Central Railway Company, chartered March 8, 1893. The company is capitalized for $7,000,000, half of which is common and half preferred stock. The property has a mortgage indebtedness of $5,086,000. The officers of the company are: President, Robert E. Sheldon; first vice-president and treasurer, Edward K. Stewart; second vice-president, Clarence M. Clark; secretary and auditor, P. V. Burington; general superintendent, M. S. Hopkins.

Trial Trips on the Wannsee Bahn

At last trial trips are being made with electric trains on the Wannsee road, near Berlin, which has been equipped by Siemens & Halske. Each train consists of nine three-axle passenger cars, each having five compartments for ten passengers each. The first and last cars have a motor on each axle, or a total of six motors. In starting, the two groups of three motors are each connected in series. As soon as a certain speed has been attained the motors on the last car are cut out. The train, which is being used for experimental purposes only, at present, is fitted with measuring instruments, which show the current consumption at all times. To compare the cost of electrical operations with steam locomotive service, the same class of measurements are made on the steam locomotive. It has been found that at the start the motors consume 200 amps., the average power at the start is 600 hp, and during the run about 300 hp is required. The time taken to get the train up to full speed (40 km per hour) from a standstill is ninety seconds, while during this time the train passes over a distance of about 500 meters. The train is completely braked in thirty seconds within a distance of 170 meters. According to this, the distance between Berlin and Zehlendorf being 12 km, the trip can be made in twenty-seven minutes, and the stops about one minute in length. This schedule must be adhered to when the train is fully loaded, *i. e.*, twenty-nine axles, 220 tons, including the weight of the 410 passengers.

M. K. McMullin, of Pittsburgh, has purchased control of the West End Traction line of that city. It is supposed that the road has been bought in the interests of the Union Traction Company.

The Metropolitan Railway of Paris

A glance at a map of Paris showing the omnibus and tramway lines of that city would appear to indicate a system of transportation so complete and so well calculated to meet every requirement that any additional facilities to this end would be unnecessary. No matter what part of the city a person may wish to visit or where the starting point may be, there is a possibility of reaching the destination with very little trouble—with or without transfer to another line—provided the traveler has an intimate acquaintance with the routes followed by the various "busses" and tramcars and understands the eccentricities of the transfer system. Every important street has, in fact, one or more lines of cars for the use of the public, and the grand boulevards are crowded during the busy hours with omnibuses from all the principal quarters of Paris. The only relief from this congestion of traffic lay in diverting a portion of it into other channels; and, since an elevated structure would be quite out of the question in a city which prides itself on the beauty of its streets, the only alternative was an underground railway. It is many years ago since such an undertaking was first considered, but really definite action was not taken until after the last Exposition. It may be that the need for better transit facilities was felt when the influx of visitors occurred at that time, but the only satisfactory solution of the problem presented itself when electric traction became a practical method for application to transportation systems, and when there was no longer any doubt as to its reliability and its many advantages for underground work

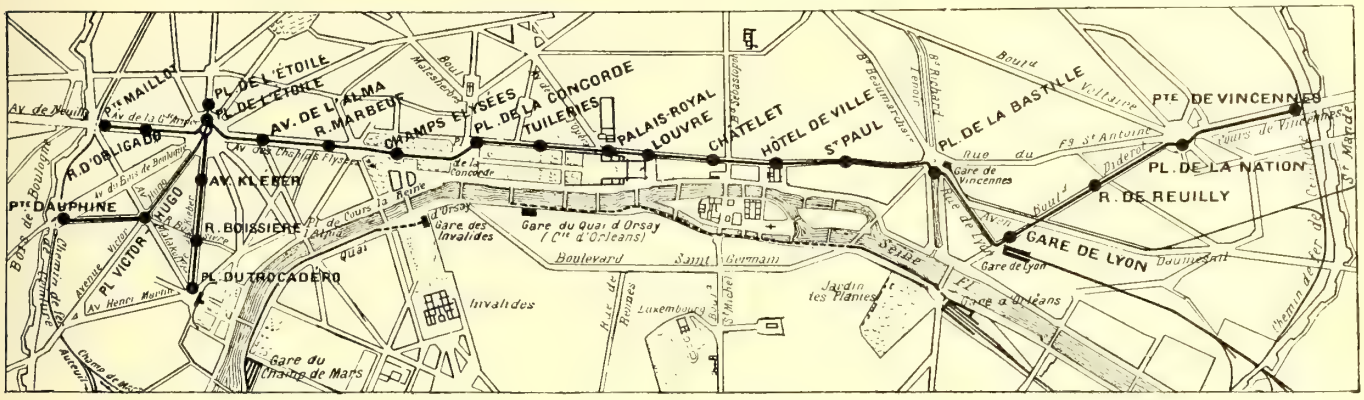


FIG. 1.—MAP OF PRESENT SECTION, PARIS METROPOLITAN UNDERGROUND RAILWAY

Four years ago the city authorities decided to build a metropolitan railway. They appeared to be particularly desirous that their road should be independent of the railroads of the State; therefore, they concluded that a narrow gage track should be used, this requirement having the additional advantage of reducing the expense of building the road. However, a State law passed in 1898 authorizing the city of Paris to build the railway, specified that the standard gage of 1.44 m should be employed. The maximum width of the cars over all was given as 7 ft. 10½ ins., and a clearance of 27 ins. was required between car and tunnel wall at a height of 6 ft. above the rails.

The Metropolitan Railway as at present projected will be remarkably comprehensive in service, and will form a network of lines almost rivaling those of the surface. The first to be constructed is one running from the Bois de Boulogne on the west to the Bois de Vincennes on the east, traversing the city through the center and following the right bank of the river for a considerable distance. Another line is to be constructed following the old boulevards and forming an irregular figure called by courtesy a circular path. This supplements the Ceinture, or Belt, Steam Railroad, which passes around the city on the inner side of and close to the fortifications. It may be compared to the inner circle of the London Underground Railway and will doubtless be of great value, passing as it does through the center of the Southern district and through the thickly populated sections in the northern part of the city. The third important line runs from east to west a little to the north of the first-mentioned line, and a fourth passes through the center of the city from north to south. Two other lines are to be built, one to provide direct communication with the different trunk railways having termini in the eastern part of the city; the other to be mostly open cut or elevated, and but little underground, connecting the Vincennes line with the belt line at its southernmost point. The three lines which pass through the city from east to west or north to south have their terminal points at the Fortifications' Belt Line, or Ceinture Railroad, which will give additional transportation facilities.

The whole network of the system is not yet under construction, as it was decided to undertake the work by sections. The most important line, especially in view of the Exposition, was that connecting the western part of the city with Vincennes, where the machinery and transportation exhibits are installed. This line, which is that shown on the map, starts at Porte Dauphine, one of the city gates leading to the Bois de Boulogne, and passes through the Place de l'Etoile, then down the Champs Elysées past the Tuileries and the Louvre, through the city to the square where once stood the Bastille, and on to the gate of Vincennes. In order to accommodate the

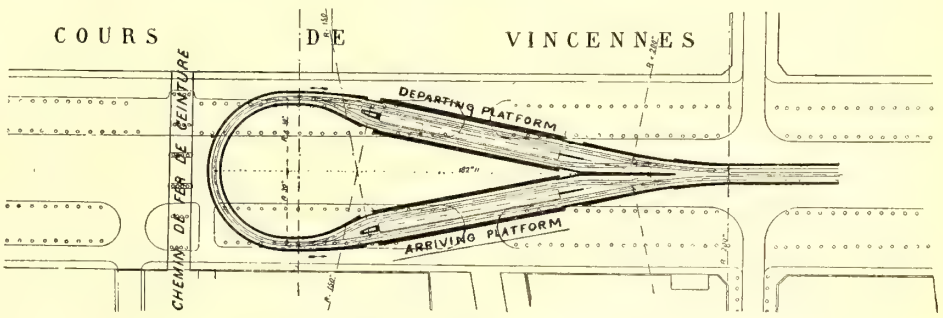

FIG. 2.—PLAN OF LYON STATION, SHOWING PLATFORMS FOR ARRIVING AND DEPARTING TRAINS

crowds of people desirous of visiting the Exposition, a branch line has also been carried to the Trocadero from the Place de l'Etoile, as shown, this forming part of a circular line to be built in its entirety only after the close of the Exposition. An extension down the Avenue de la Grande Armée to Porte Maillot has also been made. The

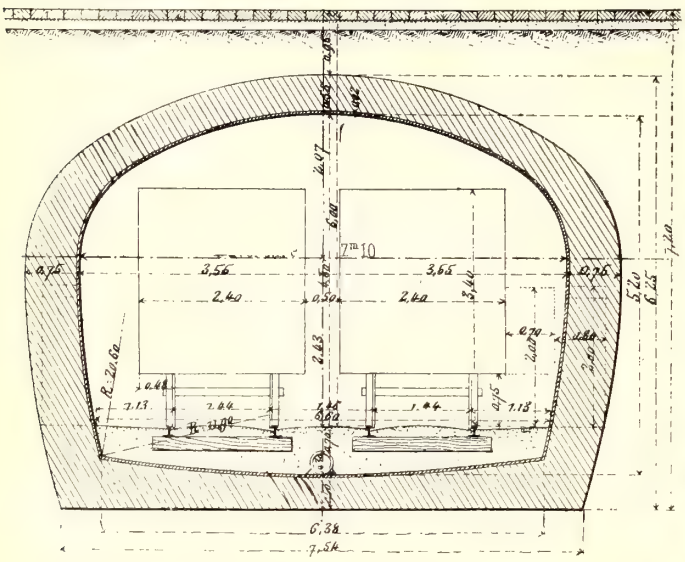

FIG 3.—SECTION OF STANDARD TUNNEL

railroad, then, from Vincennes to the Place de l'Etoile, together with the three branches to Porte Maillot, Porte Dauphine and the Trocadero, form what is called the first fraction of the underground system. It is this portion which was formally thrown open for public traffic on July 16. It was at first intended to have the opening on the 14th, which is the great national fête, corresponding to our own Fourth of July, but it was feared that the rush of people would be so great as to paralyze the road, as there would not be more than perhaps twelve trains running, and the streets of Paris are always thronged on the 14th with pleasure seekers, and immense crowds go out to the Bois de Boulogne to view the parade of the troops.

The direct connection established by the Metropolitan Railway between the main buildings of the Exposition and the far-removed annex at Vincennes should have the result of increasing the attendance at the latter place. Up to the present time there has been no means of transportation between the two divisions of the Exposition other than that afforded by circuitous street car routes or boats on the river, excepting the use of cabs, which the general public cannot afford. The boats stop at innumerable landing places, making a very slow trip, and the steamboat

FIG. 4 —VINCENNES STATION READY FOR OPERATION

companies have not considered it worth while to put on an express service, possibly because they are satisfied it would not pay.

The length of the line at present in running order is 7 miles. The construction throughout is underground, except at the Bastille, where it was necessary to cross the St. Martin Canal, necessitating an open-air stretch which includes the station. The curves at the approaches are also exceptionally sharp, there being at one side a double curve with radii of only 165 ft. At the terminal stations

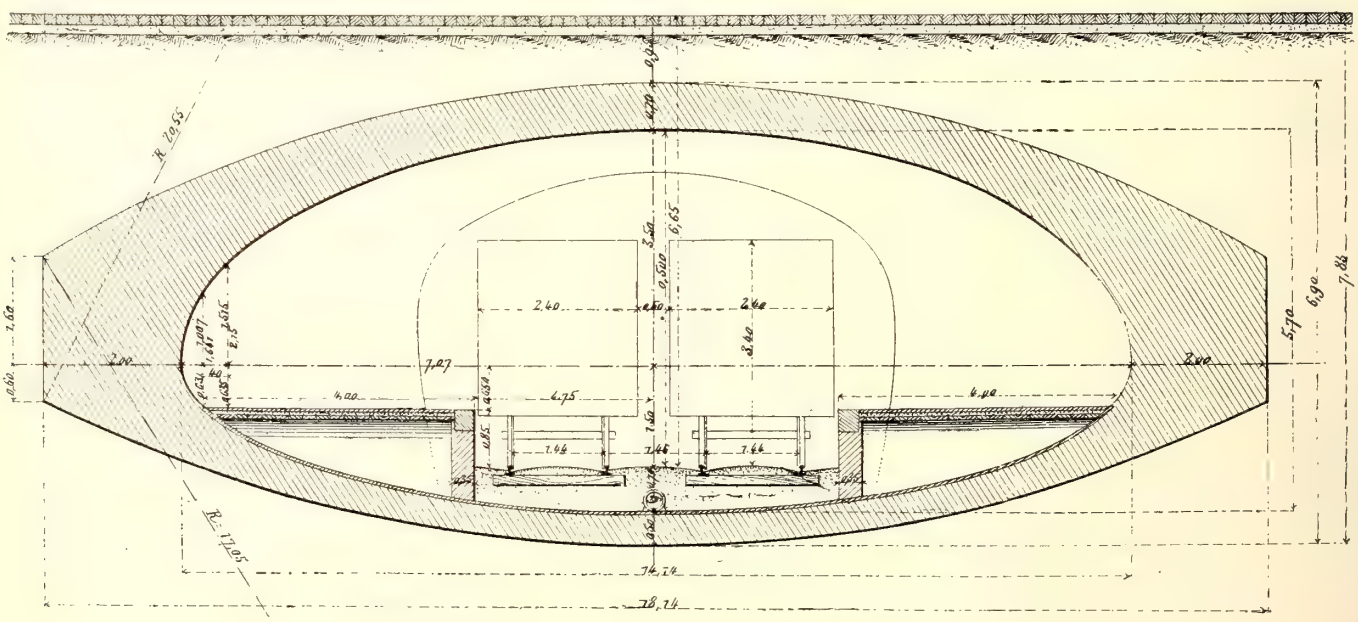

FIG. 5.—CROSS SECTION OF VAULTED STATION

the trains are brought round a loop after discharging the passengers, this arrangement allowing of rapid handling of trains, such as would not be possible in a station of the ordinary type except by the use of a considerable number of shunting tracks. Since it is not intended to transport any heavy baggage on the Metropolitan system, hardly any greater delay may be anticipated at terminal points

than at some of the important stations in the city. As a measure of precaution, however, the terminal loops are each provided with a double-track station on one side for arrivals and one on the other side for departures (Fig. 2), thus giving plenty of time for manipulation of trains. The two stations are joined by a circular section of single track laid in a narrow tunnel, the radius being uniformly 30 m, or less than 100 ft., at all the terminals. It is to be remembered, however, that the trains are hauled around these curves unloaded. On the main line, except as noted above regarding the Bastille station, the shortest radius of curve is about 250 ft. The steepest grade is 4 per cent.

The ordinary tunnel section is shown in Fig. 3, the maximum width of the straight tunnel being nearly 23 ft. 4 ins., and the height above the rails 14 ft. 9 ins. On the sharp curves the side walls are carried out further, giving additional clearance of about 7 ins., necessitated by the regulations imposed by the government, which require a minimum clearance of 27½ ins. between the car and wall at a height of 2 m above the rails. This law also fixed the maximum allowable width of car at 7 ft. 10½ ins.

On the direct line from Porte Maillot to Vincennes there are sixteen intermediate stations, and each terminal has, as we have seen, two stations entirely independent. Three different plans of construction have been adopted. The more usual form is that of a vaulted roof with a clear height above the rails of 5 m (about 16 ft. 5 ins.) (Fig. 5); but some of the stations are built with an iron roof with brick arches between the beams, and one station—that at the Bastille—is entirely open. The iron roof has been used only in cases where, in order to avoid trouble from water, it was found expedient to keep the level of the rails as high as possible, the vaulted roof requiring a greater depth On this account the low-lying stations between the Champs Elysées and the Louvre, inclusive, as well as those at the Hotel de Ville and Gare de Lyon, are built with the iron roof—a cut and cover system (Fig. 6). The general dimensions of the stations are, for the length about 246 ft., and for the width 45 ft. or 46 ft. The platforms, raised about 3 ft. from the rails, are 13 ft. wide.

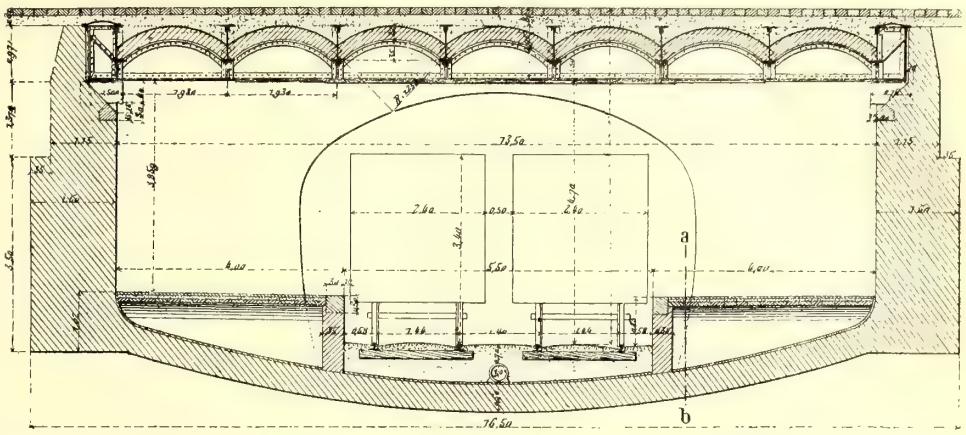

FIG. 6.—SECTION OF STATION WITH IRON ROOF

The regulations imposed by the city on the builders of the road require that no obstructions shall be placed on the streets; this means that the view across the squares or streets must not be cut off by the erection of any covered entrance to the underground stations. In consequence, the only intimation of their whereabouts is afforded by a painted board giving the name of the station, standing over the flight of stone steps, surrounded by a light railing, which lead to the passageways below. Since the depth at which the rails are laid is not more than 20 ft. to 25 ft. below the surface of the street, very little head-room is available for the building of ticket offices. Sufficient height is, however, provided for all persons, even those exceptionally tall, the lowest roof being about 6 ft. 10½ ins. At the foot of the stone stairway leading from the street is the ticket office, which may be a hall some 15 ft. square, with one side partitioned off for the ticket agents and with a counter for "gratuitous change of money." From this hall a passage conducts to the stairways communicating with the platforms, a foot-bridge being provided for crossing from one side of the station to the other. The halls and passages, as well as the more important stations, are lined with white enameled tiles, so that the rows of incandescent lamps provided for illumination are quite effective. The station of Lyon will doubtless have a large traffic from the Gare de Lyon, the terminus of the railway to the Mediterranean, which station is within a stone's throw. It will be seen that there are two platforms in the Lyon station (Fig. 8), which is built with the iron roofs supported on two rows of columns extending down the platforms, the whole interior being well illuminated by incandescent and arc lamps. The rails are laid for one double track only, which is the Porte Maillot-Vincennes line. The other platform is intended to serve the trains which will eventually run on the belt line, for it is at this point that the two lines meet, having the stations

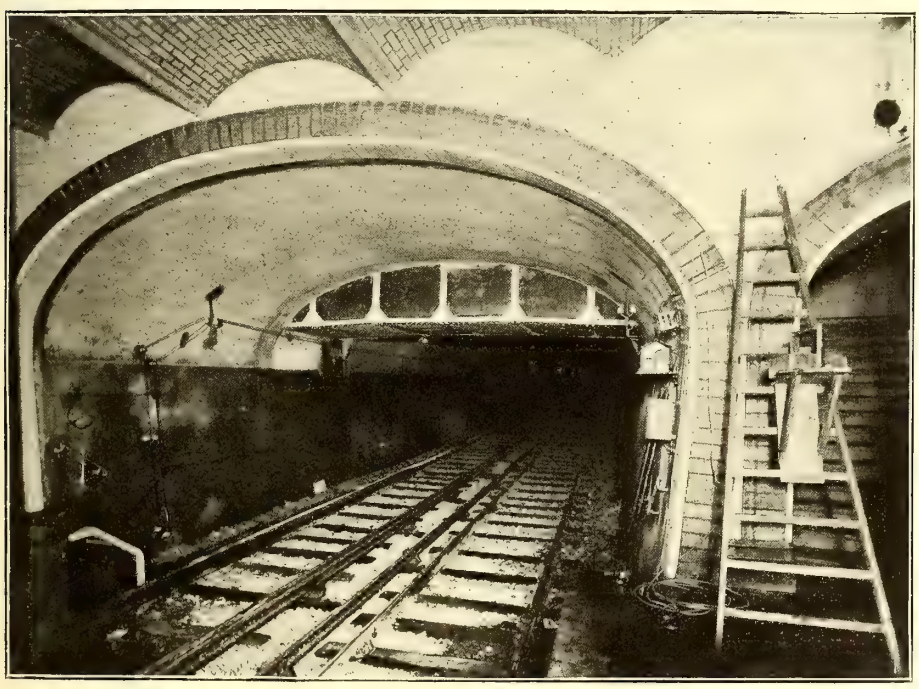

FIG. 7.—VIEW LOOKING DOWN TUNNEL FROM HOTEL DE VILLE STATION, SHOWING BLOCK SIGNAL SYSTEM

of Reuilly and Place de la Nation also in common, and separating after the latter, the belt line curving round toward the north, and the Vincennes line going east. Owing to the economy in space rendered necessary by the small amount of head-room available at some of the stations, also with a desire to avoid building long stairways to give access to the trains, the foot-bridges furnishing communication between the two sides of stations dip considerably into the tunnel cross section. In the photograph

FIG. 8.—INTERIOR OF LYON STATION

taken from the Hotel de Ville station looking down the tunnel (Fig. 7) it will be seen that the bridge is quite low, clearing the car roofs by only a small margin. This construction effectually prevents use of the railway by the

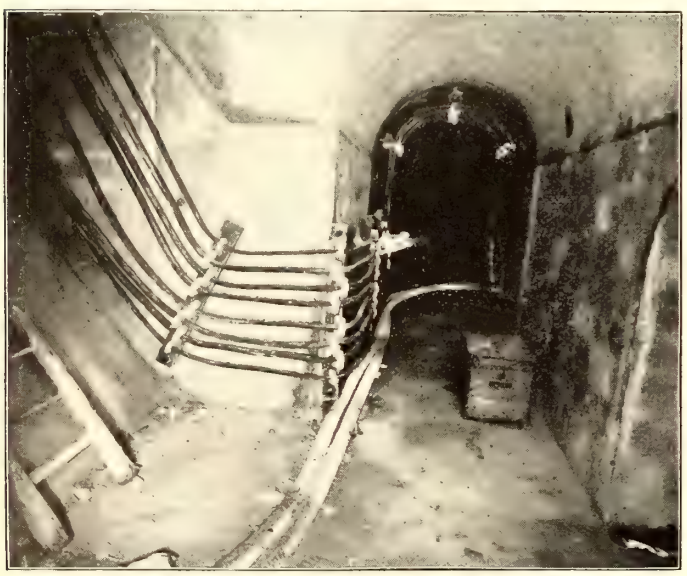

FIG. 10.—CABLE VAULTS AND GALLERIES AT PLAC DE L'ETOILE

rolling stock of the State roads, the Metropolitan cars being only about 11 ft. 2 ins. in height above the rails.

The junction of the several lines at the Place de l'Etoile has demanded a most extensive system of underground tunneling at that site, but the additional requirements of a sub-station for electric power, and large rooms for accumulators, together with elevator pits and accommodation for the necessary operating machinery and water tanks, have combined to make an elaborate honeycomb of subterranean galleries, halls and stairways, without mentioning the three immense stations. Thus the Triumphal Arch above may well be held to represent a new triumph, not of war, but of architectural and engineering skill, executed amid countless difficulties in the depths of the earth over which the stately monument is raised.

At the Etoile station one line passes beneath the others, requiring very deep excavation in order to build the lower station. For passenger service two elevators will be installed, intended principally for the lower, but available for the upper, stations. The elevator pits, solidly built with

FIG. 9.—UNDERGROUND VAULT FOR TRANSFORMERS, PLACE DE L'ETOILE

masonry walls, have a depth of 57 ft. 6 ins. As yet there is no machinery installed, the walls and passages being too damp. On the lowest story a large transformer station has been built, measuring nearly 100 ft. x 50 ft., with a high vaulted roof (Fig. 9). The row of columns down the

FIG. 11.—STATION OF VINCENNES—PORTE MAILLOT LINE AT PLACE DE L'ETOILE

center are intended to support the rails for two traveling cranes by Rondet and Schorr, of 12 tons and 6 tons capacity, respectively. The foundations shown in the illustration are intended for rotary converters and static transformers, of which three sets are now to be installed. For temporary use one of these sets is placed in a shed at the opening of the eastern elevator shaft. Both the rotary and the transformers are built by Schneider & Company, Creusot. The former is supplied on the alternating side with six collector rings, and takes current at 430 volts from

three single-phase transformers fed from an incoming 5000-volt, three-phase line, giving on the direct-current side an output of 1000 kw at 600 volts.

In order to insure the service of trains at all times and to act as a regulator to the supply, two batteries of 250 Tudor accumulators are to be installed, with a capacity of 2000 amps. each for one hour. For the reception of these batteries two double rooms have been built, one above the other, with a floor area in each of the four sections of 72 ft. x 23 ft. The floor is covered with a special acid-proof bitumen, and has a gentle slope toward one end in order that any liquids spilled may run off into a drain. The ceiling of the lower rooms is formed by beams, but that of the upper rooms is carried around in a semicircle from the floor, being, therefore, 11 ft. 6 ins. in height.

The rooms which are to receive the hydraulic plant will be 40 ft. long by about 30 ft. wide, with a height of 18 ft. Here are to be three electrically operated pumps and pressure tanks for the elevator service. Connection with the sewers from this room is obtained by means of a shaft sunk 70 ft. below the floor level. Ventilation among the different chambers of this underground installation is pro-

FIG. 13.—EXIT OF CHAMPS ELYSEES STATION, SAME DESIGN AS ENTRANCE

vided by means of galleries extending in all directions, some being used to conduct the cables from the transformer room to the railway (Fig. 10). In this engraving it will be seen that a heavily insulated cable lies on the ground, this being provided temporarily to bring in the 5000-volt current from a power station at Asnières, in the northern part of the city, at present supplying the needs of the railway. The cables held in cleats are 550-volt supply wires passing up the inclined opening on the left to the railway tunnel, where connection is made to the third rail, by which power is delivered to the motors of the trains.

Returning now to the other stations along the route, Figs. 11 and 12 show two typical views, Fig. 11 being that on the through line from Vincennes to Porte Maillot. At the ends of the platforms are the stairways leading out and the foot-bridge over the railway. On the further platform is a railing surrounding a stairway which gives access to the galleries leading to the lower station. The entrance to the stairway is on the platform of the adjoining station. This adjoining station is illustrated in Fig. 12, in which a track is shown with a line of contractor's cars used in transporting earth. A good idea is obtained of the extent of these stations, the further end being lost in darkness, notwithstanding the powerful flash light used in photographing. This Trocadero branch of the Metropolitan system has not been put in service as early as the through line, although the intention was to provide special service for the Exposition. The real value of the railway, as far

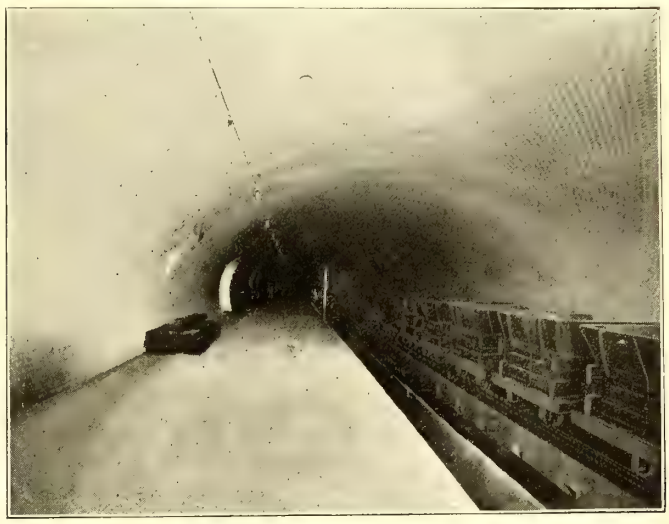

FIG. 12.—INTERIOR PLACE DE L'ETOILE STATION, TROCADERO BRANCH

as it concerns the great show, lies in the facility it has provided for visiting the annex at Vincennes, an extremely interesting section, but little known by the general public.

The first stop after leaving the Porte Maillot terminal is at the Champs Elysées station, this being one of the principal entrances to the Exposition, close to the Palaces of Fine Arts and the splendid Alexander III. bridge. The illustration (Fig. 13) shows the style of entrance and exit, no structure being allowed, other than the signboard, to stand above the street level, except when the station is outside what may be called the select part of the city, as at the Bastille and beyond. The Champs Elysées station is graced on the outside by majestic lions on pedestals, but these adornments are actually part of the architectural

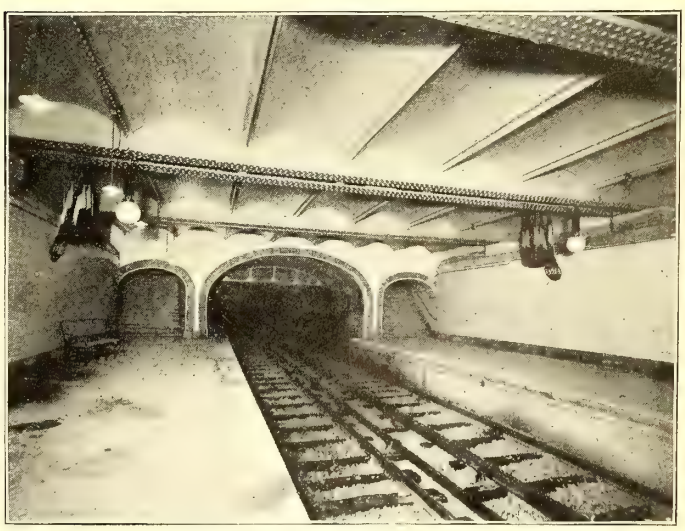

FIG. 14.—INTERIOR OF CHAMPS ELYSEES STATION, SHOWING EXITS

decoration of the Exposition gates leading to the two Palaces of Fine Arts, of which the larger one is visible in part. The interior of the Champs Elysées station may be seen in Fig. 14, which shows a decoration of French tricolor flags for the opening festival. In the distance the electric lights dotting the sides of the tunnel show the

curve of the line toward the Etoile, the absence of smoke allowing a clear view along the track. For the illumination of the station both arc and incandescent lamps are used, the current being taken from the power supply mains. The ticket office of this station is of the same type as those used throughout. Entrance is obtained by stone steps open to the sky, and the traveler is confronted with a notice requesting him before purchasing a ticket to get change at the bookstall, the agent being obliged to give his services in that regard free of charge. The tickets are of the ordinary size, made of pasteboard. Return tickets are issued for second-class only and are not available on the outward half after 9 a. m. The cost for single tickets is 5 cents a trip first class, 3 cents a trip second-class, and 4 cents return second class. The company operating the road under lease from the city (who builds it) does not appropriate all of this amount taken in, however, small as the fares are, but, in order to cover the interest on the city debt and other obligations, the company is required to pay 1 cent on every 3-cent or 4-cent fare and 2 cents on every 5-cent fare received, as well as a tax on the number of passengers carried beyond a total of 140,000,000 in one year.

FIG. 15.—VIEW IN TUNNEL PORTE MAILLOT—VINCENNES LINE

FIG. 19.—ENTRANCE TO BASTILLE STATION

FIG. 16.—TRAIN IN HOTEL DE VILLE STATION

A view down the tunnel from this station (Fig. 15) shows well the general construction. For the track Vignole T-rails are used nearly 50 ft. long, weighing 106 lbs. per yard, and for the conductor a third rail, double headed, weighing nearly 79 lbs. The track rails are laid on metal ties 7 ft. 2½ ins. in length, spaced about 36 ins. between centers; every third or fourth tie is 6 ins. longer on the inner end, and carries the insulator for the third rail, which consists in a cast iron chair supported on two iron pins fitted to an iron base insulated by wood and protected by overhanging flanges on the chair.

The Hotel de Ville station is one of the most important, being situated within the busiest portion of the city. Fig. 16 shows a train in this station and on the platform some of the railway company's engineers. The ordinary train is composed of one motor car and two trailers, but three trailers are used when the traffic becomes heavy. The cars, to which reference will be made later, are first and second-class, and combination first and second; all the motor cars are second-class. The trains are run at intervals of a few minutes, and Dardaud's electric block system is about to be put into service, operating automatically. The signal is on the tunnel face, as seen in Fig. 7, and the wires leading to the further connections are clearly shown in the previous figures.

The Lyon station (Fig. 17), already mentioned, is likely to have extensive patronage. A desire on the part of the railway company to avoid accidents during rush hours has probably prompted the posting of the notice, "Attention aux 3 marches!"—"Look out for the three steps!"—which greets incoming passengers from the bright light of the street, who otherwise might fall in their hurry to reach the train. From the platform below there may be seen (Fig. 18) at the western end of the station a blank wall having the appearance of a tunnel bricked up and plastered alongside of the actual tunnel through which trains are continually passing. This is where the belt line will join the present line at some future day, and, making use of the same tracks for a distance of about a mile, will leave again at the station of Place de la Nation to continue a northerly course. The Lyon station has two sets of double tracks, one for each division.

The Bastille station, being of necessity built over the canal, is more in evidence than any other part of the railway system. The entrance is from the square, and the bridge over the tracks is on this level, together with the ticket office. It is a pleasing contrast to find a stopping place above the surface of the ground, and the station is decidedly airy and bright. We have already spoken of the

sharp curves rendered necessary at this point, and the photograph taken along the platform (Fig. 20) shows the bend of the tracks as they enter the tunnel. The rails also show distinctly in the bright light. It will be observed that the joints are not opposite, nor do they alternate with regularity, but they are placed nearly opposite each other. Long copper bonds ½ in. in diameter unite the track rails, passing over the fish-plates; the third rail has short, flat bonds.

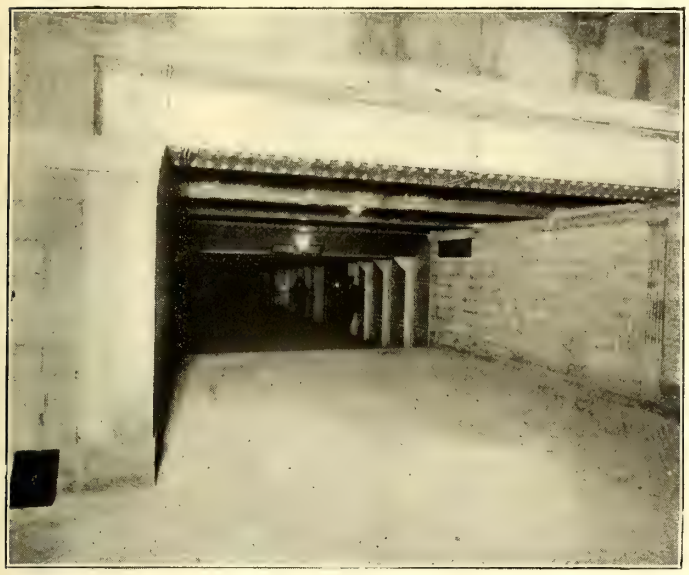

FIG. 17.—ENTRANCE TO LYON STATION

FIG. 18.—TUNNEL AT LYON STATION

The photograph of the Vincennes station (Fig. 4) is taken on the departure platform. It will be remembered that a separate station is built to receive incoming trains, two tracks being used in each case, one on either side of the platform, and the two stations are identical in design. Beyond the stairway the two tracks join and pass by way of a narrow tunnel to the other station. The platforms are of sufficient length to permit of two trains standing on each side, thus allowing of convenient storage. At this end of the line, however, there has been provided a car house, to which a branch line is run from the loop between the stations. The accompanying engraving (Fig. 21) shows the building in course of construction, and the yard outside, which will be laid with tracks, accommodating 150 motor cars and trailers for the present. The first order for motor cars called for forty-six, and at the time of starting the road there were twenty-two delivered, twelve being furnished with controllers at each end, so that they may be run in either direction, and ten having a single controller. The single-controller cars are intended for use on those sections of the road where loops are used at the terminal stations, as there is then no necessity to provide for running backward, and the double-controller cars may be used when switching is resorted to for changing the direction of travel.

One of the double-controller motor cars is shown in Fig. 22 standing in the yard of the car house. A steep incline communicates with the Ceinture Railroad above, where some car bodies may be seen on the freight cars ready for unloading. The motor cars, 29 ft. 6 ins. in length, are furnished by the Ateliers de Construction du Nord de la France, whose factories are at Blanc-Misseron (Nord). Double frames are provided, one to support the car body and one for the truck, this design allowing the removal of the upper portion without interfering with the lower. The trailers, however, supplied by the Franco-Belgian Company, of Raismes, have but one frame, painted black, while the upper frame of the motor cars is painted red, in order to make them more readily distinguished by train

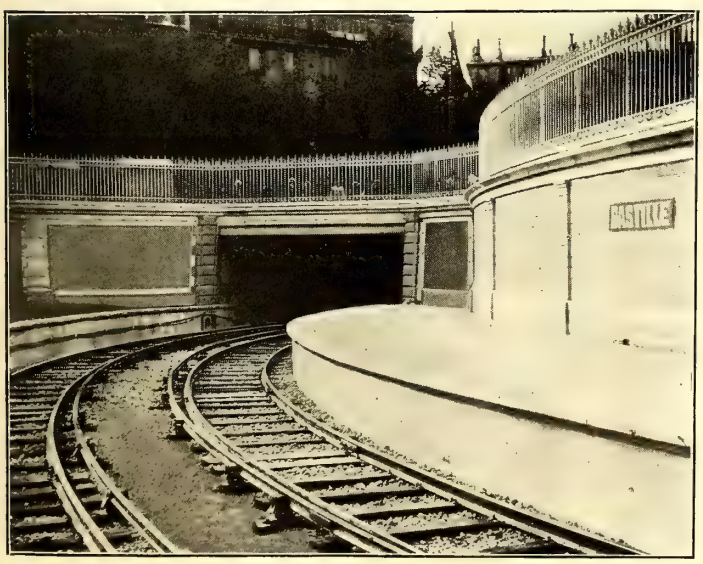

FIG. 20.—BASTILLE STATION, SHOWING THIRD RAIL

FIG. 21.—INTERIOR OF VINCENNES CAR HOUSE

hands and perhaps to give some brightness to the front of the train. Both these car factories are close to Valenciennes, in the Department Nord of France. The car

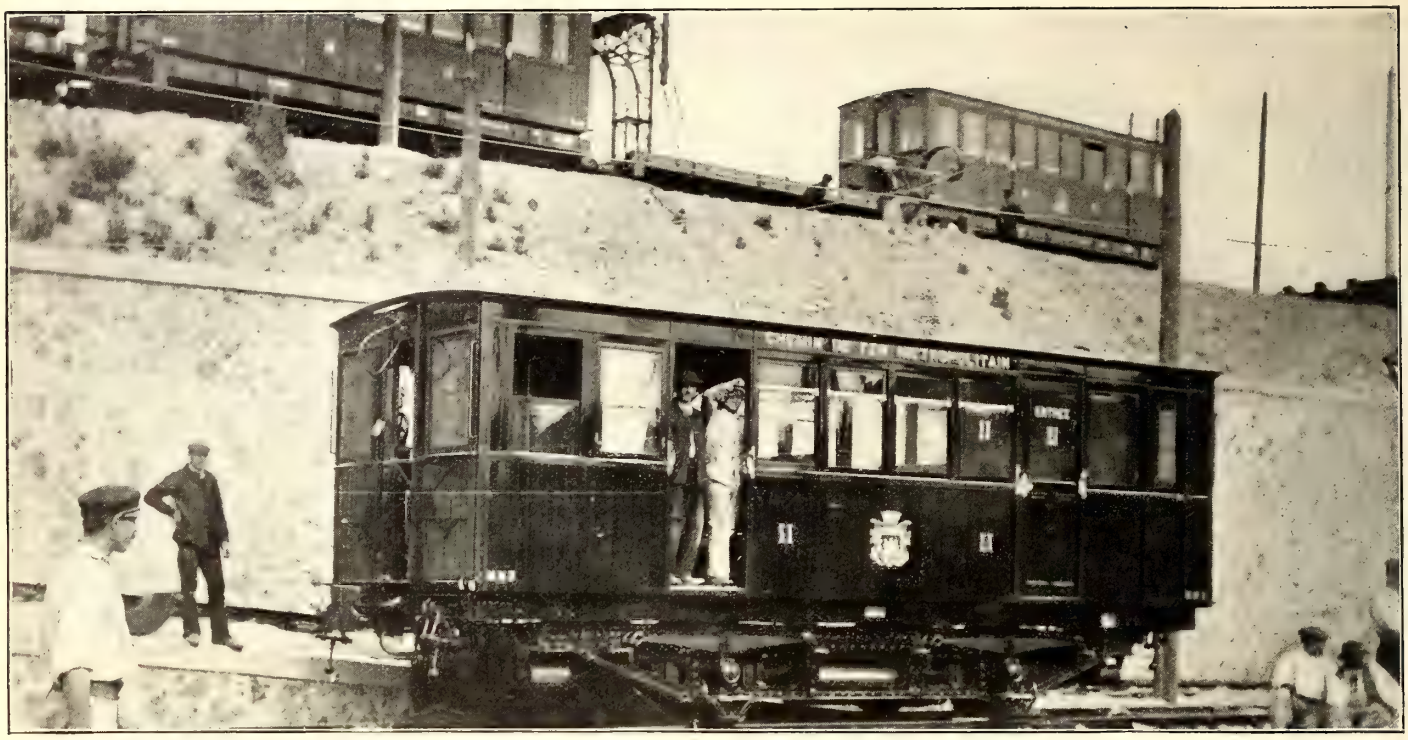

FIG. 22.—DOUBLE CONTROLLER MOTOR CAR

wheels are of forged steel, made by Baume & Marpent, and have a diameter of nearly 33½ ins.

The Metropolitan Railway Company is to be congratulated on its choice of motors, as there is no doubt that its selection of Westinghouse material in this respect has eliminated from the railway system all possibility of breakdowns, besides providing thoroughly reliable and substantial apparatus whose value will be more appreciated as repair bills are found to be low. In some other directions the railway company is perhaps not so fortunate, but is possibly desirous of assisting home enterprise.

The motors supplied by the Westinghouse Company are of 110-hp type, No. 70, two motors being provided for each motor car. In a short compartment at the end of the car is the fine large controller, of the new standard 98-A. type. In the roof above is an automatic circuit breaker, car type, and on the other side, against the partition, a toggle-joint fuse box carrying a copper wire fuse which is replaceable in a moment if burned out, and which may be easily removed if it is desired to open the circuit to prevent tampering. A Wurts lightning arrester is placed alongside the fuse box, of the ordinary form for cars.

All the above apparatus is by Westinghouse, but the air brakes are of French make. They are made by Soulerin, of Paris, and air compressors and motors are furnished by Amelin & Renaud, also of Paris. These motors, of the spherical ironclad type, are connected by gears to the compressor, which has two cylinders 90 degs. apart, and supplies air to a reservoir in which the pressure is kept at about 65 lbs. per square inch. The output of this motor is only 1½ hp, which is rather low.

Contact to the third rail is obtained by means of two shoes of the ordinary double-link form. In the car depot an overhead construction is used, and it will be observed that two wires are used, on which a four-wheeled carriage runs, passing through the loop-shaped supports. A cable from this carriage is fitted with a plug, which may be pressed into a socket on the motor car, providing by this means a connection to the controller and motors.

The motor cars are lighted by eight lamps of 16 cp, and two lamps on the outside of the cars at the head of the train. Also in the small vestibules at the end there are lamps which may be switched in, instead of one of the interior lamps. The trailers also carry ten lamps.

The start of the line was made with twelve trains of three cars each; one motor car, one first and second-class combined, and one second-class. The motor cars are all second-class, and carry twenty-eight passengers, seats being provided for twenty. The seats are back to back, some accommodating two persons, or three, and some being narrow seats for one person only. Plenty of room is provided in the middle of the car, with the object, it is

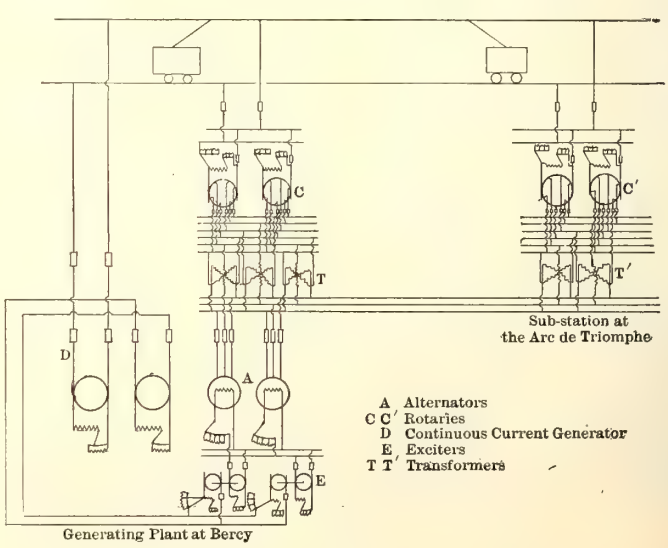

FIG. 23.—SCHEME OF ELECTRICAL DISTRIBUTION

said, of facilitating circulation. It has been said that only twenty to twenty-five seconds will be allowed for stops at stations, but, while this may seem a very short time to the French mind, it is about double the time usually required

on the London Underground Road, except on occasions of heavy traffic.

The power station which is to supply current for the Metropolitan Railway is in course of construction. The site is near the Lyon station on the banks of the Seine at Quai de la Rappé. The equipment of this station will include three batteries of six boilers each; one 1500-kw direct-current, 600-volt engine and generator; three 1500-kw three-phase, direct-connected engines and alternators delivering current at 5000 volts and 25 cycles, and rotaries, exciters, storage batteries, etc. Under ordinary circumstances the direct-current set will be used to supply the line in the immediate neighborhood of the station, but, if necessary, power can be taken from the alternating-current board. At present there are only two sub-stations. The scheme of distribution is shown in Fig. 23. The boilers at the main station are of the semi-tubular type, and will supply steam at 142 lbs. per sq. in. The engines are vertical, compound, condensing, though capable of working with free exhaust, and are fitted with Corliss valve gear. Their cylinder dimensions are 1800 mm and 1100 mm x 1500-mm stroke (70.9 ins. and 43.3 ins. x 59 ins.); each engine is fitted with a fly-wheel weighing 63,000 kg (138,600 lbs.), and operates at 70 r. p. m. The rotaries at the sub-stations are of 750 kw capacity each. A section and plan of the main station are given in Figs. 24 and 25. Fig.

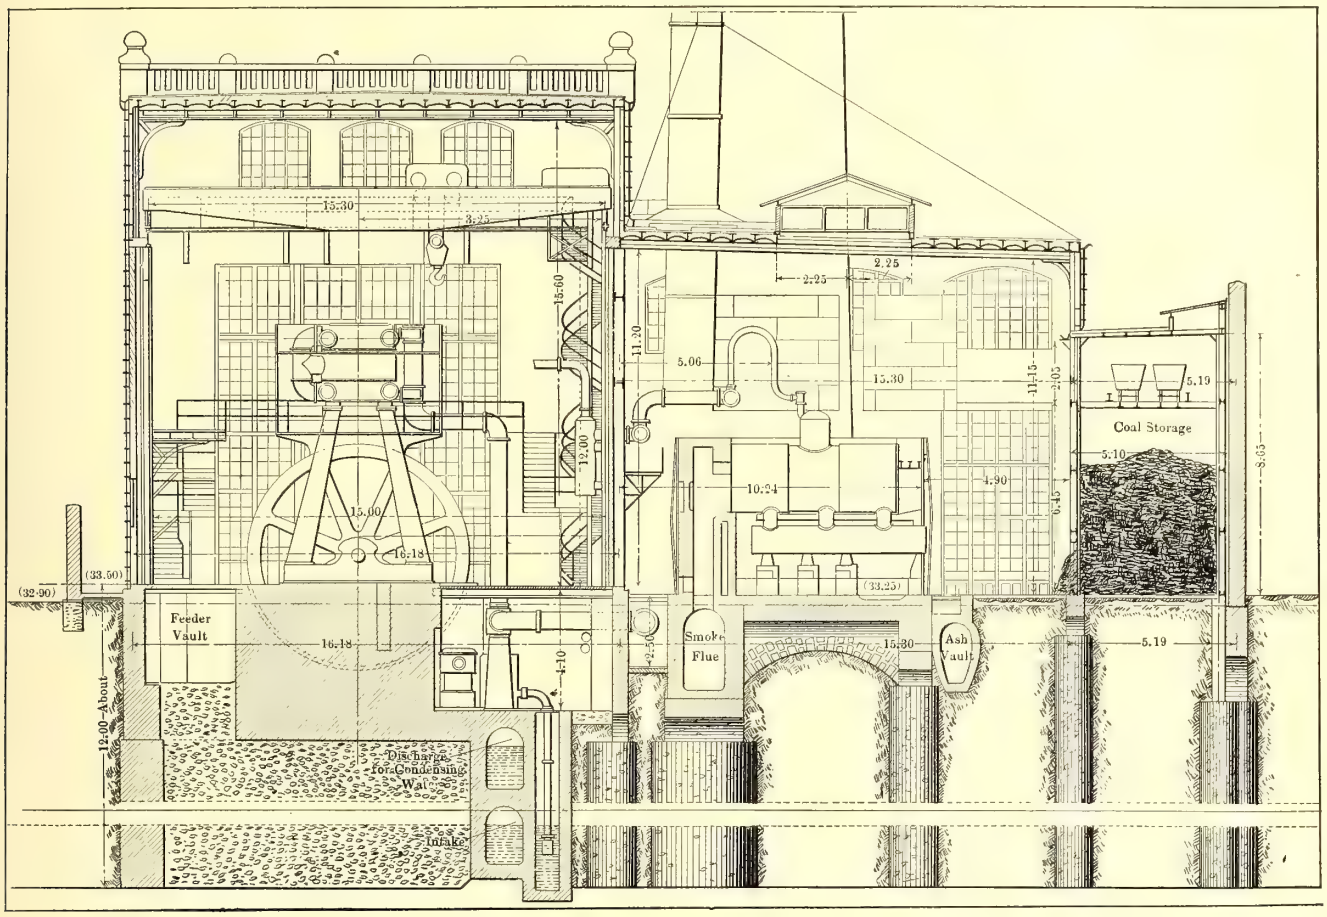

FIG. 24.—TRANSVERSE SECTION OF POWER HOUSE

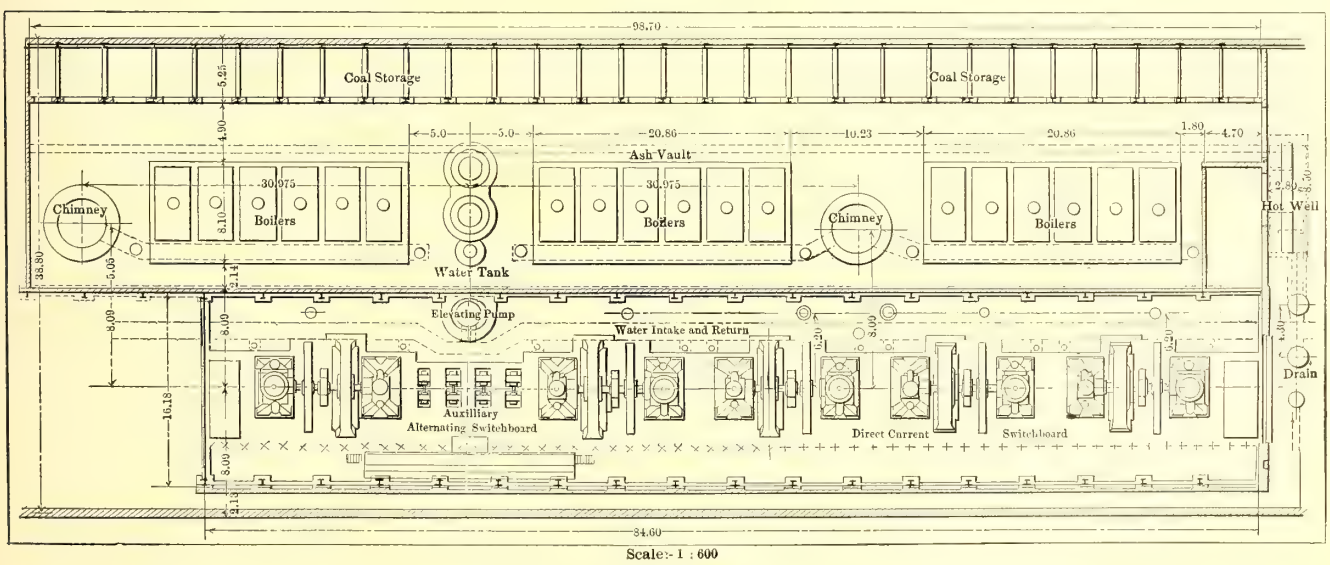

FIG. 25.—PLAN OF POWER HOUSE

26 shows the exterior of the station. The whole station outfit is to be provided by Schneider & Company, of Creusot.

One of the chief reasons that the Parisians in general were not aware of the extent of the subterranean work going on was that so little surface activity was visible. The reason for this was that arrangements were made for transporting the excavated earth by tunnels to the river. Four such tunnels were built, one at the Avenue d'Antin, above the Champs Elysées station, another at the

FIG. 26.—EXTERIOR VIEW OF THE POWER HOUSE

Place de la Concorde, another at the Louvre station, and another close to the Hotel de Ville station. By this means the streets were kept clear of an endless succession of carts loaded with earth, and the process of excavation could be pushed more rapidly to completion. This comprised the sections between the St. Paul station and the Champs Elysées. Near the Bastille the earth was removed by canal-boats, for the remaining sections of the line convenient points were selected, from which loaded carts could be sent to the river without seriously interfering with regular street traffic. Such points were at the terminal stations of Porte Dauphine and Porte Maillot, the Place de l'Etoile, Gare de Lyon and Place de la Nation. Nevertheless, as soon as the tunnels could be laid with rails a great part of the transportation of excavated earth was directed to the special tunnels, even from a distance.

The engineer in charge of rolling material and electrical equipment for the Metropolitan Railway Company is Henri de Grièges, who has seen a great deal of American practice in extended visits through the United States. The general director of the company is Mr. Maréchal.

The Westinghouse Company has a capable and experienced engineer in Philip Salberg, who has been superintending the setting up and operation of the material furnished by them. Mr. Cocquillot, road foreman of electrical equipment for the Metropolitan Company, has contributed largely to the initial success of the undertaking by careful and conscientious work in the important position which he has filled.

Electric Railway Possibilities in the Philippines

BY G. D. RICE

Better transportation facilities in the form of electric lines are urgently required in the first and second class cities of the Philippine Archipelago. The writer has visited most of these cities and has talked with the leading merchants of Manila and Iloilo and other cities, and the universal opinion is that such lines will pay well. American enterprise and push are securing a hold, and the largest towns, especially the two cities mentioned, are rapidly becoming Americanized. Nearly all other cities in the Orient, many of them smaller than these two cities, have already street railway lines in successful operation, and new ones are being built, and it will only be a question of time when the electric car will be as familiar a sight in the principal cities of the Philippine Islands as it is in the United States.

The conditions in the cities mentioned in these islands have greatly changed during the last few months. New business houses have opened in large numbers in the outskirts of the cities, while many private residences have been erected by persons who have been driven in from the interior by the recent wars of the guerilla bands. The territory covered by Manila and Iloilo, which, like other Oriental towns, is very large, has become greater than ever before, and the indications are that the expansion will be greatly increased before the close of the present year, for there are many contracting firms at work putting up business houses, factories and private dwellings. At the present time the working classes are obliged to walk or hire carremettas or bull cars, and as most of the workers get only about 20 cents a day, it will be seen that they cannot afford to hire expensive traveling outfits. The only street car line in Manila now is operated by animal power, the stunted native horse being employed. Only a few cars are run, and these at long intervals. These cars, however, are filled to the point of overflowing by the natives, so there is no chance for the ordinary traveler to get on. The road need not be considered as a factor in the traffic of the city, although it might be used as a basis upon which to establish a modern form of railway line. In Iloilo there is no street car line, but instead there are lines of busses and carremettas. These do a good business, but cannot begin to accommodate the people who desire to travel.

Owing to the fact that most of the streets in Manila are very narrow, special plans in the establishment of an electric system would have to be adopted. There are a few main thoroughfares which are broad enough for all practical purposes, but such streets are few compared with the narrow ones. These narrow streets are going to interfere with the improvement of the cities of the Philippines for many years, and possibly until the streets are widened by tearing out alternate blocks. Only the shortest cars can be employed in these narrow streets, and probably a narrow gage would have to be adopted, as in many of the European cities. The sidewalks are also narrow, and in many cases the span wires will have to be attached to the buildings on each side of the streets. In Iloilo a standard gage road can be used, and the suburbs of Manila are also suitable for standard gage tracks. The streets in both cities are crowded not only with vehicles, but with pedestrians, who walk in the streets. This would interfere to a considerable extent with the speed attainable, but it seems to be the general opinion that if an electric line were built much of this traffic would be diverted to it, and that the effect would be to reduce considerably the street congestion.

An advantageous condition for the construction of lines in these islands is the fact that stone for ballast can be secured very cheaply. There is found here in the mountainous sections of Luzon and Panay vast quantities of so-called sandstone, which not only makes a good ballast, but is an excellent building stone. Many of the churches and bridges in the islands have been constructed of this stone, and it has been found very desirable. Taken altogether the outlook for electric traction in the Philippines is exceedingly good.

The First Five Years' Experience in Maintaining the Niagara Gorge Railroad

BY GEORGE A. RICKER

Some æsthetic souls, whose observations concerning Niagara Falls Mr. Slicer has compiled in "The Niagara Book," doubtless held up their hands in horror at the mere suggestion of building a railroad in the Gorge of the Niagara, but I do not believe they can harbor resentment against us, for the tracks hugging the shelf at the foot of the great cliffs and winding their way beside the waters look for all the world like toy tracks that embryo engineers in their childhood build, with cars running slowly up and down, seeming no larger than the plaything trains they used to wind and watch with breathless interest in their perilous career across the floor. These good people failed to appreciate the depth of the canyon, and rightly feared the destruction of its beauty. It was indeed inevitable that the appearance of the Gorge should, for a time, suffer by the operations of building, as displacing the foot of the slope in excavating for the roadbed meant that its equilibrium would be disturbed, that slides would take place and carry with them some of the vegetation which covered the talus. A year or two sufficed to re-cover these bare spots with shrubs and vines, that, growing in such luxuriance, when viewed from the highlands above seem like landscape gardens, blending with their varied foliage the deep tranquil blue of the skies with the snowy white and brilliant greens of the rapids below. All lovers of Niagara, and surely those who entertain feelings of special admiration for the Whirlpool Rapids, must, it seems to me, take pleasure in the keen delight of the eager throngs that view the splendid panorama of the Gorge from the vantage ground of the new road. Before the railroad was built but little could really be seen of this wondrous spectacle. At a few points only visitors could get narrow glimpses of the tumbling waters, from stairways and crevices in the cliffs; now the whole river from the Falls to the silent depths at Lewiston can be seen and enjoyed.

While it is not known who first conceived the idea of building the railroad in the Gorge, it is certain that two well known Buffalo men, Benjamin Fenton and Ensign Bennett, were the first to actually undertake the difficult work. It was their intention to build a road from the Maid of the Mist Landing in Prospect Park to the Whirlpool, with narrow-gage tracks, to be operated by steam, for it must be borne in mind that even so recently as 1886 an electric railroad was not practicable. The opposition met by these gentlemen from vested interests was so great that they finally abandoned the work.

In 1889 another prominent Buffalonian, Captain J. M. Brinker, purchased the franchise of the Whirlpool Company, and reorganized the enterprise under the name of The Niagara Falls & Lewiston Railroad Company. The line was continued beyond the Whirlpool through the Gorge to the village of Lewiston, where connection was made with the New York Central Railroad and with the steamers for Toronto. At the Niagara Falls end of the line the location was changed to ascend the talus, and by climbing the high bank the city of Niagara Falls was reached, where connection was had with the other railroads reaching that point. The courts sustained the new company, as they had failed to do the Whirlpool Company, granting to it the right of eminent domain. From this time rapid progress was made in securing the necessary right of way, either by purchase or by condemnation.

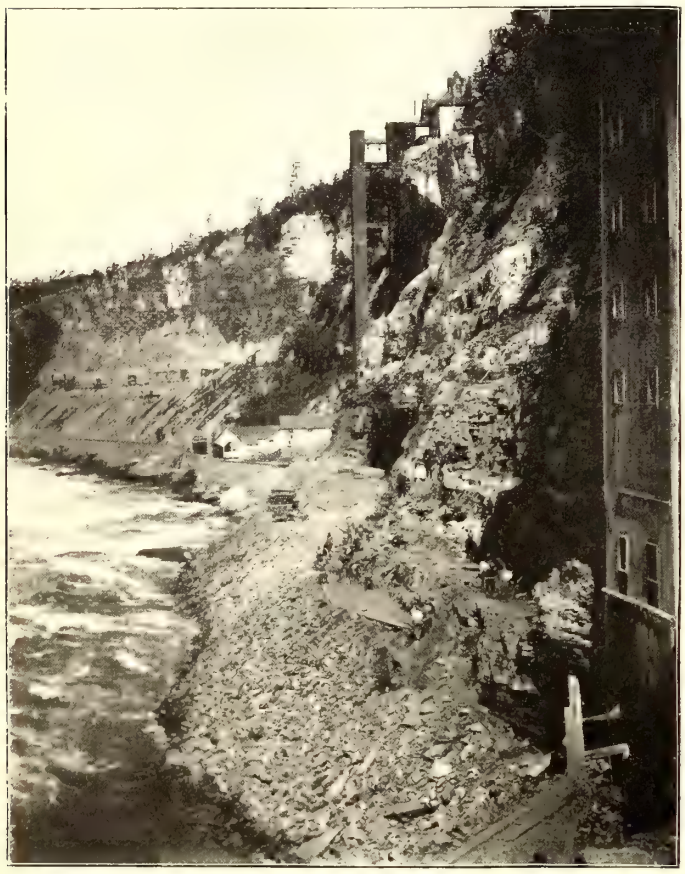
Probably no more difficult railroad survey was ever attempted than this. The slopes, which from the uplands seem to be covered with soft verdure, and to present no great obstacles to progress, were found to be at close range almost impenetrable jungles of underbrush. Shrubs and trees in countless varieties were intertwined and bound together by the wild grape vines, grown to such density and strength as only the wild grape can, when undisturbed for many years. Much trouble was experienced in the insecure footing, as nicely balanced rocks of great size would roll down the slopes, crushing everything before, from the weight of a man climbing over them. The work of the survey was hazardous in the extreme, for not only was the vegetation dense and the footing insecure on the talus, but for a distance of about one-half mile below the railroad bridges, nearly vertical cliffs extended from the Highlands to the rapids below. At several points in this section men from the engineer corps were lowered over the cliffs and flags placed on projecting ledges where they might be seen from the top of the bank on the Canadian side. Base lines were established on Canada's side of the river, from which the flags were located by triangulation. Beyond this section, and continuing to Lewiston, the line was run following the curving bank of the river, and as nearly as possible 20 ft. above the average water level. Just before undertaking this survey I had returned from railroad location in the Rocky Mountains, and was imbued with the idea

BEGINNING WORK ON TALUS NEAR LEWISTON

that nothing in this part of the world could equal the difficulties I had met in the canyons of the Rockies. After locating the Gorge road my views have been substantially modified, for, although the cliffs of the Western canyons exceed many times in height the walls of the Niagara, nowhere are there to be met the difficulties inseparable from the tremendous forces working in the Niagara rapids.

Construction of the road was begun on April 11, 1895, by Crage & Tench, contractors, of Buffalo, who furnished men and tools and their services, for 10 per cent of the force account. Beyond a profile, which it was found impracticable to follow, no detailed plans had been made since the survey. The method adopted in building was aptly described by one of my rodmen, when he said, "It was by main strength and awkwardness." My orders were to build a railroad in this unpromising place, and I proceeded forthwith to obey. Had classification been attempted, two kinds of material would have been named: loose and solid rocks, as the talus is made up of large and small stones with not enough earth to fill the interstices, and no cementing material, although the roots of dense vegetation helped to hold in place and maintain a much steeper slope than would otherwise have been possible. The deep channel of the river afforded the very best place for wasting the material excavated, and work proceeded rapidly. From 600 to 1000 men were employed, and the

first 5 miles roughly completed; one track laid, and the work train reached the southern terminus Aug. 25 of the same year. On the inner side of the roadbed a slope was formed that would stand for the time being, which meant that heavy rains and the frost in the coming spring would bring down large quantities of material left on the steps above. Crossovers were placed at such point as seemed to threaten, and from time to time as slides occurred the road was operated with single track in section, and large numbers of men quickly removed the encroaching talus.



THE OLD BUTTERY ELEVATORS AND CLIFFS WHERE VERTICAL ROCK CUT OF 100 FT. WAS MADE. LOOSE ROCK, SHOWN BY SLOPE, WASHED AWAY NOW

Several large slides took place in the early part of 1896 and again in 1897, but the quantity decreased each year until the spring of 1899, when but trifling amounts of earth and stone were found after the frost had come out of the ground, indicating that a condition of stable equilibrium had been reached. The slopes are now fully covered again with vegetation, and have taken on their former appearance of stability and beauty. Many culverts were necessary in this lower section of the road, but fortunately few bridges were required. Near the village of Lewiston a small stream in a deep gully, running into the river from the foot of the Lewiston escarpment, is crossed by a timber trestle 124 ft. in length, and 42 ft. high. Two miles further up the line is a 70-ft. decked span latticed girder over a gully, formed by another lateral stream, into which for years the New York Central Railroad, which is located about 150 ft. above us, has wasted its surplus earth and rock. These two bridges are the only structures in the lower 5 miles of the road, and the wooden trestle will be replaced in the coming winter by a steel viaduct. The latticed girder bridge put in last summer replaced the earlier wooden structure. The tracks for the entire length of the road are ballasted with rock borrowed from the talus; no crushing was necessary, as in many places clear slides of small stone, not much larger than ordinary broken stone ballast, was found, furnishing an almost unlimited supply of excellent ballast. The ties are of cedar, except on the steep grades, where oak was used, and all are of the standard steam railroad sizes and spacing. The rails were rolled by the Carnegie Steel Company, weigh 60 lbs. to the yard, and are of the "American Society" section, No. 110. No attempt was made at mathematical alignment, as the roadbed followed the irregular outline of the natural slope. None of the curves is at all sharp for the slow rate of speed required by the schedule, and all that are less than

ONGIARA POINT, VIEW TAKEN DURING SURVEY

300 ft. radius are protected with guard rails. A timber guard extends the entire length of the road outside of the outer rail.

Construction of the upper section of this railroad, beside the rapids and to the top of the high bank in Niagara Falls, was much more difficult and tedious. South of the old Buttery Elevator, at the terminus of the first year's work, began almost vertical cliffs, extending from the top of the escarpment to the seething rapids below. Drills and men were lowered over the cliffs to the first ledge, about 100 ft. above the grade line, and blasting operations carried on mostly by hand. The blasts were fired usually at noon, when hugh quantities of rock were thrown into

ONGIARA POINT, VIEW TAKEN AFTER COMPLETION OF ROAD

the river, disappearing beneath the tumbling waters of the rapids, without seeming in any way to obstruct the stream or to change in the slightest degree the curve of the waves. The vertical cutting averaged nearly 100 ft., and estimated roughly, 100,000 cubic yards of rock were thrown into the river from this one-half mile of line. At the site of the old Van Horn elevator, about one-fourth of a mile below the railroad bridges, in a deep recess in the cliff, an attempt was made to construct the roadbed in the swift current of the rapids. This experiment I believed would be futile, as a powerful stream of water was constantly discharged

upon the new embankment, diverted from the main current by a large boulder, about 50 ft. from the cliff. It was evident that this bed had been excavated by the same powerful agency, and it was but waste of time and money to attempt to place in its way any structure less substantial than the cliff, which it had cut out. I speak in some detail on this point, as it has since proved to be one of the most difficult parts of the roadbed to maintain. During a period of high water in the spring of 1897, when the river rose 19 ft.

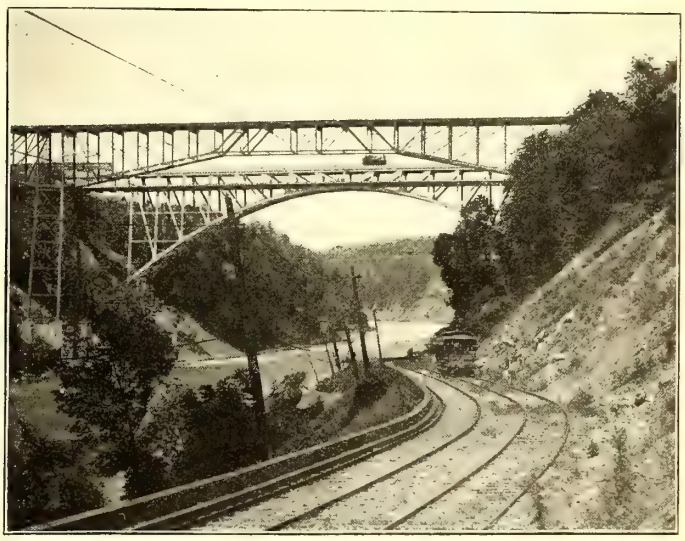
GIANT ROCK ON LEFT, DEVIL'S HOLE RAPIDS ON RIGHT. VIEW TAKEN DURING CONSTRUCTION

ALMOST VERTICAL CLIFFS, MOST DIFFICULT PART OF SURVEY. VIEW TAKEN JULY, 1886

above its ordinary level, some of this embankment was carried away. A substantial crib of large timber, which replaced the embankment, was in turn washed out in 1898, after which the company determined to do what it might profitably have done at first, and the cliff was blasted away and a shelf made of sufficient width for a single track.

During the early part of the summer of 1899 the old Niagara Falls & Lewiston Railroad Company became seriously embarrassed, and its property passed into the hands

THE LONG GRADE. FALLS IN THE DISTANCE. VIEW TAKEN AUGUST, 1899



FINISHED ROAD, CANTILEVER AND NEW STEEL ARCH BRIDGE VIEW TAKEN AUGUST, 1899

of a new corporation, at the head of which, as president, is General Francis V. Greene, of New York, and as vice-president, Herbert P. Bissell, of Buffalo. These gentlemen and their associates, after thoroughly reorganizing the enterprise and placing it upon the most substantial financial basis, proceeded to the practical reconstruction of the entire road. Operation in 1899 was not begun until July, when most of the work was finished. The talus having, as I have already said, been reduced to a condition of stability, the greater part of the work consisted in protecting the embankment from erosion by the rapids. The general method followed is best described as "enrockment." This consists in riprapping or paving the slopes with very large stones. To accomplish this a specially constructed flat car, carrying an electric derrick, was built, and has been in constant use for several months. Two men operate this car, and as many additional as are necessary assist in taking out the stone and replacing them in strengthening the embankment. Long stretches of the outer slope have been thus protected, and this work will proceed until all exposed surfaces will be entirely covered in the manner described. At the bay referred to, where the original embankment was washed away, the river from the ledge or shelf on which the inner track rests as before described, has been filled with large stones out to the great boulder of Niagara limestone, and these stones are so arranged on the outer side as to present the appearance of being carefully paved. Protection for the second track has thus been provided, and the substantial character of this enrockment is such as to resist for all time, in my opinion, erosive action of the waters. Beneath the cantilever steel arch bridge the tracks are gauntleted, passing over two latticed girder spans in front of the bridge piers. The total width between the faces of the cantilever footings and the deep waters of the river was but 13 ft., and a single track was therefore unavoidable. This is the only point upon the line where the road is so contracted and operation is carefully guarded by stopping approaching cars by the use of suitable signals, and a watchman constantly on duty.

From the bridges to the top of the high cliff, a distance

of nearly a mile, the average gradient is 4.7 per cent, the maximum 6.4 per cent, and the total elevation overcome is just 200 ft. Continuing beneath the New York Central's five tracks the line sweeps sharply to the right on a curve of 50 ft. radius, the sharpest on the line, and from thence parallels the Central for a few hundred feet, reaching Second Street in Niagara Falls, where connection is made with the tracks of the Niagara Falls Street Railway. The views herewith show stages in the progress of the work, and were taken by Mr. Arnold.

Operation of the Niagara Gorge Railway is continued from the first of May of each year to the first of March of the following year. March and April, I may state positively, are the only months when the loose material from the cliffs falls upon the slopes of the talus. This is, of course, when the frost is coming out, and small stones which have been wedged out by the ice are loosened. Since beginning operation of the road in 1895 to the present time, no passenger or employee has ever received injury from falling rocks. I was daily over the road during its construction, and have many times since passed from the Falls to Lewiston and return on cars or on foot, and have never seen a rock fall. It is my opinion that with due care, and such is most certainly maintained by the present management, the maintenance of this railroad need not be excessively expensive, and that the same safety of operation can be obtained as is secured on any mountain railroad.

Since the acquisition of the railroad at the top of the bank on the Canadian side by the International Traction Company and the reconstruction of the Suspension Bridge at Lewiston, a belt line has been in operation, over which cars of the Niagara Gorge Railroad Company pass, starting from Niagara Falls, and going to Lewiston by both railroads, making the trip down the Canadian side across the Suspension Bridge and up the Gorge; and also in the reverse direction. The extraordinary beauty of the scenery from the commanding heights on her Majesty's side of the river, combined with the grandeur and wondrous effects of the rapids, which Hawthorne describes as "an impetuous river of snow," affords to the traveler an experience which is at once unique and impressive beyond power of words to describe. The river is itself so fascinating that I am loath to leave it for other scenes, but that the public appreciates the belt line is shown by its generous patronage.

The report of the passenger department of the Gorge route for the month of July, just passed, shows an increase of 35 per cent in passengers carried over the corresponding month in 1899 and this, in spite of the recognized fact that this year at Niagara Falls has been so far a dull one. The managers of all other attractions complain of the scarcity of people at the Falls this year, but the Gorge route is prosperous, and its management well satisfied with the showing of the road.

A new feature has been added to the attractions of the Gorge by illumination of the rapids at night. Trains are made up at the Falls, and run to the rapids, where an hour or more can be spent in contemplation of the beautiful spectacle, the lamps are hidden from view, and their rays projected over the waves by reflectors, so arranged that the illumination is most effective. In addition to the arcs, a large searchlight, mounted on a flat car, takes position some distance below the observation platforms, while its powerful beams are thrown against the waters and screens of green and yellow interposed, producing most beautiful effects. The roar of the waters against the walls of the Gorge, the depth of the canyon in the darkness of the night and the frowning cliffs above produce upon the onlooker a feeling of awe and fascination. I am bound again to refer to Mr. Howell's eloquent tribute to the rapids, whether viewed by the light of day or the moonlike glow of the artificial illumination, I must agree with him that "I had schooled myself for great impressions * * * but I had not thought of the rapids taking me by the throat, as it were, and making my heart stop. I still think that above and below the Falls the rapids are the most striking feature of the spectacle."

The Early Wichita Electric Railway, Built in 1887

BY T. C. HUGHES

During the summer of 1885 the writer became acquainted with Dr. A. W. Adams, of St. Louis, Mo., who was at that time making some experiments in the propulsion of cars by means of electricity. His efforts had resulted in the production of a design which was considered by the parties interested therein to have met all difficulties in motor mounting. The method adopted in mounting the motor on the car is clearly shown in Fig. 1. Making arrangements to acquire a territorial right in the invention I started out to find a place and the capital to equip a full sized road with the system.

This quest landed me, during the summer of 1887, in Wichita, Kan., where I obtained the ear of J. O. Davidson, then president of the Citizens' Bank of Wichita. With him

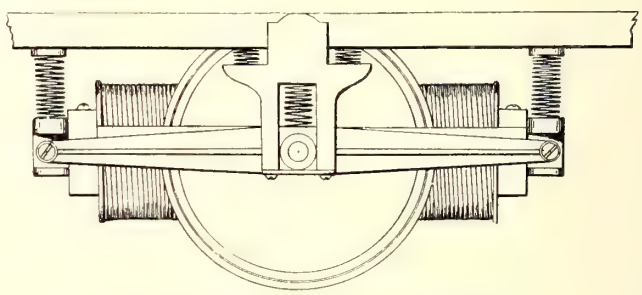


FIG. 1.—METHOD OF MOTOR SUSPENSION

and his associates I made a contract to build and equip with three cars some 5 or 6 miles of single track and switches, over a route commencing at Market and Douglass Avenue, then running north on Market to Riverside, thence west across the little Arkansas River to Riverside Addition and the Wichita Driving Tracks. From here the road extended north and west 3 or 4 miles through several new additions.

The work was commenced and carried forward both at St. Louis and in Wichita. The track was of 40-lb. Johnson girder rail, laid on ties and ballasted in the down-town portion.

A frame boiler and engine house, 40 ft. x 60 ft., contained two horizontal tubular boilers of 100 hp capacity each, a horizontal high-speed Smith, Beggs & Rankine engine of 100-hp rating, and a Brush generator, having an output of 60 amps. at 1000 volts approximately. The construction of the balance of the apparatus for the electrical equipment was in charge of W. L. Seddon, of St. Louis. The track work, power plant, etc., which was directly under my charge, progressed much faster than the manufacture of the electric machinery, and as the Wichita owners were pushing us for completion of the road within the time limit of the contract, many changes were made in the plans to procure the electrical machinery on time.

As many features of the construction were rather novel, and as no description has ever been given of them, I hope the following particulars relating to the details of this en-

terprise will prove both profitable and interesting history to the readers of the STREET RAILWAY JOURNAL.

The trolley wire was a hollow copper tube, $\frac{7}{8}$ in. in diameter and about 1-32 in. in thickness, made in lengths of 18 ft. Every 18 ft., or at the ends of each section of the trolley tube, an overhead switch was located, as shown in Fig. 2. The function of this switch was to cut out of circuit the section of live trolley wire directly over the car.

Two trolleys, pulled by a flexible cord, were attached to the roof of the car with spring clamps, one trolley being at the front, the other at the rear end of the car.

The distance between the trolleys was greater than the distance between the overhead switches, by probably 4 ft.

When, therefore, the front trolley opened the overhead switch the current would pass down to the motor through the rear trolley, and after traversing the motor would reach the overhead line again by the front trolley, the front trolley breaking all switches and the rear trolley closing all open switches, see Fig. 3. The current then reached the generator station by an independent pole line. In the overhead construction the trolley wire and switches were suspended from longitudinal cables attached to, but insulated from, cross suspension wires, fastened to wooden poles located on each side of the street. The trolley wire was suspended every 5 ft. from this longitudinal cable, each suspension wire being insulated therefrom, the return wire being carried on poles at one side of the street. At the generator station the return circuit was carried to a carbon-point automatic rheostat intended to throw in and out the field coils of generator, and thereby control the output of the latter.

The cars were of the Brill make, and were, if I correctly remember, 28 ft. over all, mounted on four-wheel trucks. The motors were mounted in a rigid frame, journaled at four points on the axles and geared to one axle with coil-wire belts. While this design of motor mounting did not conform to our ideas, we were forced to its use by stress of time to meet our contract requirements with the Wichita Company.

The trolley consisted of a frame carrying five wheels, as shown in Fig. 4. The under wheel would engage the switch points extending below the under surface of the trolley tube, and turn the wheel in the switch one-eighth of the way around, making or breaking the circuit as the case might be. Quite complicated overhead switches were designed for the turn-outs, but never erected. Instead, two wires were put up for that part of the line which extended from the power house to Douglass Avenue, with a single wire extending over the balance of the track.

In the operation of this line after construction, many difficulties were encountered, as I presume will be apparent to all electrical men, but which rather surprised the projectors at that time. Nevertheless enough experience was gained in the trial to enable the engineers to make a success out of it, except for financial difficulties in which the enterprise at that time became involved. It was then decided to abandon the series system and re-equip the road with a parallel system and to mount the motors as originally intended. This proposition was submitted to the St. Louis stockholders, but was rejected. Thus ended the first St. Louis effort to equip a practical street railway line with electricity.

The St. Louis company undertaking the work was known as the Advance Electric Construction Company, and the principal stockholders were A. W. Adams, W. L. Seddon, H. L. McPheeters, Seth W. Cobb, D. R. Francis, Charles Hoyle and Ewing Hill.

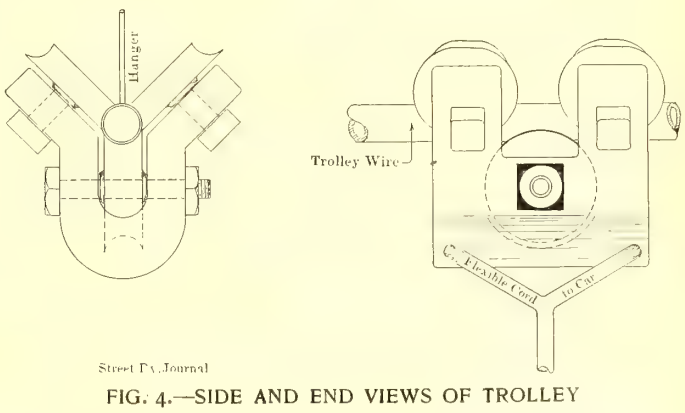

FIG. 4.—SIDE AND END VIEWS OF TROLLEY

A concession for an underground electric line in Buenos-Aires, Argentina, has been granted to Carlos Bright, an American engineer, having an office at 874 Cuyo Street, Buenos-Aires.

A railroad known as the Anglo-Argentino Tramway Company, having offices at 3583 Rivadavia Street, Buenos-Aires, has made application for permission to change its traction over to an electric system.

Can Small Electric Roads be Operated at a Profit? II and Conclusion

BY JAMES BLAKE CAHOON

An important consideration for a road operating in a small town is that of the track, for it may be taken for granted that this class of roads cannot afford, and in fact, it is not necessary for their moderate traffic to put in, as expensive a track as is necessary for the larger cities. Still, it must be amply heavy for the work to which it will be subjected, and must be so built that the repair account will be as light as possible. The City Councils are sometimes inflated with their own importance to such an extent that they fully believe that they know more about the construction of the roadbed than the railway people do themselves, and where this occurs, they are very apt to impose restrictions and specifications such as are only justly applicable to the larger cities. As a general rule, these specify that the road must lay a deep girder rail, not less than 6 ins. in depth, with a flange not less than 2½ ins. in width, through the main streets of the city, and they often compel the laying of this class of rail everywhere inside the city limits; they also impose the paving of the road between the rails and for a distance of 2 ft. outside, when, as a matter of fact, about the only paving in the city is that on the main business thoroughfare, yet they will permit a steam road to lay T rails, and often without any restrictions as to paving.

This is presumably on account of the general feeling that the electric road is going to be the most profitable enterprise that has ever been in the city. This idea is well illustrated by an actual fact that came under my own observation in an accident case that was being tried some time ago. The gist of the matter was that a man went out from his house to get a car, which was an open one, and without waiting for the car to stop, reached out for one of the handles with the intention of jumping on, but missed his grip with one hand, and was dragged for a few feet alongside the car. When the car was stopped, he recovered himself, jumped on and went on down town about his business. The conductor at the time asked him if he were hurt, and he answered in the negative. About a year afterward he brought suit against the road for $10,000 damages, on the ground that this accident was the cause of a double hernia. The evidence was practically all in favor of the road—the jury were unable to agree, and it cropped out later that the point of disagreement was solely on whether they should give the man $1,000 or $4,000, the argument in favor of giving him damages being that the road was a rich corporation, and the man was poor and ought to have something, anyway. This case was subsequently settled, in view of this fact which was brought out, for $400 in preference to letting it go to trial again. As a matter of fact, this road was only just about earning its operating expenses, and the prospect of paying any dividend was far in the dim future, yet the general feeling among people was that the road was earning a large amount of money.

Coming back to the question of track—it seems to be generally conceded that for this class of roads T rail construction is the best, and the nearer it comes to steam road construction, the better. I believe if this class of roads could build their roads with 70-lb. T rails, placed on a subfoundation of 6 ins. of broken stone, ballast them up even with the surface of the ties with the same material, fill them up practically level with the surface of the rail with ordinary dirt, or, preferably, gravel, use a long, heavy splice bar, and place ties every 2 ft., using for the latter a tie having not less than 7-in. face, 6 ins. in depth, and 8 ft. long, that the track could be maintained with a minimum amount of repairs. Even with this construction, I consider it necessary to maintain a small track gang, and keep them going over the road the year round, and this work should be done systematically and thoroughly, and not have the road gone over in a general way in the spring and again in the fall, and left to take care of itself the rest of the year. I have tried both methods, and am satisfied that the cheapest method is to keep a small gang at work continually. For the ordinary ten to fifteen car road, with a mileage of from 15 to 20 miles, three men will take care of a road built as above, and keep it in good shape without any difficulty. If, however, the road is built, as probably the majority of roads are, on the ordinary dirt foundation, there will be more or less heaving in the spring, and it will be necessary to supplement this gang at that time.

The question of paving is an especially sore point with the small railway. John W. Boyle, president of the Utica Belt Line Street Railway Company, in an article in the Utica *Herald* March 23, 1899, treated the subject of paving from a railway standpoint in a most admirable manner, and brought out very clearly the point that the street railway is not benefited in the least by paving. He states that pavements are built only at the request of abutting property owners. They secure the pavement and pay for it for their individual convenience and benefit, and this is so well recognized that the law compels them to pay two-thirds of the cost of the pavement and the city one-third, on the ground that the abutting property owner is the person most benefited. The street car is the only vehicle in the street which furnishes and keeps in repair at its own expense that portion of the street on which its wheels revolve; it is the only vehicle which neither wears out nor litters the pavement. He further makes the point that after a pavement is laid, it becomes a constant source of inconvenience and expense whenever work is necessary upon the tracks, and the railway company is expected to, and does bear this increased expense for an improvement which is made for the benefit of everyone in the city except itself.

If people want rapid transit in the small cities, the fact is beginning to force itself home that they must either lighten the burden imposed upon the railway corporations, and work with them and assist them in every way possible, or else this class of railway will be obliged to retire from business. Financial men are not, as a rule, putting their money into enterprises from motives of pure philanthropy, but do want to see and expect to receive a fair return for the money invested. If onerous laws are enacted, and penalties in the shape of paving and expensive track construction imposed, rendering it impossible for these roads to pay any return on the investment, capitalists are going to withdraw from this class of investment, which will result in either the abandonment of this class of roads or shifting the burden upon the local people. Some years ago it was not a difficult matter to float bonds to build a road in a city of any fair size, but a letter which I received only the other day in regard to financing a projected road well illustrates the feeling which bankers have in regard to these propositions at the present time. Quoting from a letter dated July 17, 1900, they say, "We regret to state that it is unlikely that we shall be interested in the way indicated, as we do not undertake the financing of companies except with a record *behind them*." Another firm of bankers, referring to the same proposition, says, "We are not financing uncompleted roads." These quotations in general illustrate the feeling among the banking element in regard to furnishing the funds for building roads at the present time. The numerous railway laws that have been passed in most of the States impose the same restrictions upon the

small road as upon the large, making no attempt to distinguish between the two, although common sense shows that a provision which might be a minor charge against a big road would be a crushing burden on a small road; it is high time that the small road, as well as the people, recognize this fact, and take the necessary steps to secure the repeal, and readjust the railway laws so that the burden, be it in the form of taxes, construction or paving imposed, shall not be more onerous to the small road than it is to the large.

I think it would be fair to assume that the majority of the small roads have been built by contract, and where this occurs, invariably the repair account is a large one; this is particularly true of the overhead line, largely due to the fact that when the roads were built the idea of calling in a consulting engineer to draw up specifications and supervise the work was not in vogue, and the result is that the line was put up in a slipshod way, with cheap materials, and has been giving out ever since. There is no part of the road where it pays to do as good work and put in the best of materials as in the line, one reason being that the pressure is on the line for about eighteen hours a day, and if the line is not well insulated there is a constant loss owing to leaks, and this loss represents coal at about $2 per ton usually. In this connection, I wonder how many of the small railways in the country make a thorough and systematic test of their lines to determine whether they are properly insulated or not. I will wager to say that not one in ten do it, the general rule being to let the line take care of itself until a break occurs in the line or an insulator gives out; they then send out and fix that particular break, return the tower wagon to its shed, and wait for another break. It is not a difficult matter to test the line out for grounds and leaky insulators, nor does it cost very much to do it, and as a matter not only of precaution but of good horse sense, it ought to be done at least once a week where there is reason to suspect that the class of insulators is not of the best; where the line is built of first-class materials, it still should be subjected to tests for grounds at least once a month. There is no better criterion of the management of a road than the general appearance of the overhead line as one goes over the town. If it has a slipshod appearance, poles out of line, the line itself baggy in one place and too taut in another, insulators with fur on them, line out of center, etc., it is pretty safe to conjecture that the road is not paying. It is not the great big things that conduce so much to economy and rendering the road a profitable investment, as it is the little things, and of these little things a general air of neatness is the chief.

The next subject that demands our attention is that of the car houses and repair shops, and how they should be taken care of to secure the best results at the least cost. The car houses of many of our small roads remind one of a junk dealer's, largely because of the small force employed and the little if any attempt made to keep things clean and in order. Gears, pinions, parts of motors, trolleys, and even cars themselves become worn out, and are thrown to one side in the corner of the car house and left to take care of themselves. Repairs are usually made wherever the car happens to be in the car house, and everything is left lying around in a perfect hodge-podge of disorder. There is really no necessity for this, and it leads to slipshod methods in the care of the cars and everything else. There is even more necessity for order and method on the small road than on the large, and the car houses should be laid out particularly to facilitate work. The car house should not be a machine shop, or a carpenter shop, or a paint shop—there should be the car house proper, in which the cars are housed, and at the rear end there should be provided separate rooms, preferably arranged as follows: Facing the car house, at the rear end and on the right half, place the wash room for washing cars, in rear of this the machine shop; on the left, the carpenter shop, and in rear of this the paint shop. Many roads wash their cars at night wherever they happen to stand on the tracks in the car house, and the result is that the car house is always damp, and consequently when a car is allowed to stand in there for any length of time, moisture gathers on the fields and armatures of the motors; after this has been repeated a few times an armature or a field burns out, and then the apparatus is blamed.

As a matter of economy, it is much better to have a separate wash room with proper drainage, wherein the cars can be washed. In this connection the care of the cars comes up, and after trying various methods, I am thoroughly convinced that the best is to provide a sufficient number of cars so that every car may be thoroughly washed, cleaned and given a brief overhauling every other day, doing this in the daytime, and not at night. Night inspection of car equipments and washing of cars do not accomplish the best results. When the cars come in after the day's run, half of them should be run on a track so that they can be taken care of in the manner indicated on the following day; the other half should be gone over to see that the grease cups are full, and brushes and brake mechanism in good working order. This small amount of inspection can be done by the night fireman of the power house, assuming that the car houses are situated as they should be, alongside of the power house. In addition to the inspection mentioned above, motors should be dropped from the cars periodically and thoroughly overhauled in the machine shop, commutators turned down, new bearings put in, and any general repairs needed to the motor equipment done at this time. In regard to the car bodies themselves, the utmost care should be taken to see that these are kept up in a cleanly condition and looking reasonably bright. Under ordinary conditions of operation, cars will need revarnishing once a year for two years, and the third year they should go into the paint shop and have the paint removed down to the wood, being repainted afresh. Many roads make a contract with some local painter to do this, while other roads, operating ten to twenty cars, find that they have work enough to keep a painter busy the year round. I believe the latter plan to be the better one.

The ordinary working force required to take care of cars of this size road under these conditions are a good machinist and helper, a carpenter who is also a blacksmith and general allround handy man, a painter, and a lineman who is also an armature winder and can take care of repairs to the armatures and fields, in addition to looking after the line and acting as starter to get the cars out in the morning. To keep things looking somewhere near decent, it is advisable to have the car houses and all shops thoroughly cleaned and inspected once a week, the rule I followed being to have the men clean up Saturday afternoon, then I would thoroughly inspect all buildings on Sunday afternoon. We built a bin in the rear of the machine shop, into which all broken gears, pinions and scrap of all kinds were thrown, and a junk dealer came regularly the first of each month and cleared this out. There were no excuses taken for the buildings not being thoroughly clean and in good order at the times mentioned—they simply had to be, and once the men understood this, there was no further trouble. One result of this was to make the men careful in their work, and to overcome the natural tendency to waste things, and the consequence was a marked decrease in our repair account. In the power house, where there was little

necessity for disorder or dirt, everything was required to be clean and in good order by 10 o'clock daily. There was very little trouble about this, as engineers are usually proud of their machines and take good care of them.

After all that has been said in regard to the property itself, when we come right down to the meat of the matter, the success or failure of a road depends very largely on three factors: First, the manager; second, the employees, and third, the cordial co-operation of the two preceding. As a rule, the class of men making up the employees of the small roads are drawn from the town itself, usually born and brought up there, and on the great majority of roads more or less difficulty is encountered in keeping the same men in the service continuously, due largely to the fact that the young fellows in the course of two to five years want to get into something that will pay better, and incidentally take them more out of the public gaze, many of them being inclined to look on the occupation of conductor of a street railway as pretty near the next thing to working on the street with pick and shovel. Hence it is that the younger element do not make as good conductors as the married men with a few years added to their age. This does not seem to be true of the motormen, and it is hard to discover a reason for it. I remember at one time a bright young fellow, who had been a conductor for some three years, and who, during this time, had an almost perfect record, came into the office one day and said that he had decided that he wanted to leave our employ. I sounded him a long time as to cause, and finally elicited the fact that he was engaged to be married, and the young lady to whom he was engaged did not like the idea of his working any longer as a conductor, and much preferred that he seek some other work. I asked him what he had in mind, and he said that he had been offered the position of brakeman on one of the steam roads. I told him I would give him a vacation for three months, and if at the end of that time he still entertained the same feelings in the matter, I would accept his resignation; if he did not, he could continue with the company. At the end of two months he came to me and said that he and the young lady had come to the conclusion that after all it was better for him to stay in the employ of the company, and so far as I know, he is there to this day.

It is often remarked that the discipline on this class of roads is not as good as on the larger, yet I see no reason why the discipline should not be better, provided the characteristics of the men are carefully studied. There is, of course, a tendency among them to be more or less hail-fellow-well-met with all their friends, and as they do not have to be as much on the alert, and look after things as sharply as on the large road, there is a tendency to chat with the patrons of the road and take life as easily as possible, but this can be counteracted through the cultivation of a proper esprit de corps, and infusing into the men the idea that on their efforts largely depends the financial success of the road. The manager comes more into contact with each individual than can possibly be the case on the large road, and hence has a chance to instill much of his individuality and methods into their minds and lead them in such a way that they are glad to work for the interests of the company. Many roads do practically nothing for their men, and when the advisability of establishing a club room for their employees is mentioned, they dismiss it with the single remark, "Oh, we cannot afford to do that." As a matter of fact, they are the very people who should afford to do it.

It does not cost very much to fit up a waiting or club room for the employees, with a billiard and pool table and the current literature, with a few good books of reference and some of the standard games. I believe I was the first manager of a small road to do this, as also to introduce the longevity system of paying the men and giving them service stripes in accordance with the number of years of service, and certainly I did not, and I know the men never regretted the taking of this step. Prior to this the men had no place to wait for cars whose men they were to relieve, and consequently drifted into saloons. In this particular town, all cars came into a common center, and the relief was made there. The car houses were situated nearly 2 miles from this point, so that it was practically impossible for the men to have any headquarters there. At first I took one fairly good-sized room on the second floor of a block on the corner of the main business street, at a point where the road turned the corner. From this the men could see their cars coming, and be ready to meet them promptly.

In fitting up this room, it not being large enough for a billiard room, and I being at the time unable to get other quarters, I carpeted the room, heated it, and provided card tables and several of the common games, like backgammon and cards, and the daily papers, including a New York paper, the weekly illustrated papers and half a dozen of the illustrated monthly magazines; there were also provided enough chairs and odd tables to take care of the average number of men who would find their way in there, as well as a clock and a telephone. This worked so well and showed such good results, that by renting the whole of the second floor of this block, I was able to secure a large room adjoining the former one, which we fitted up as a billiard room, putting in the tables and paraphernalia at the expense of the company. The question that came up in my mind at this time was how to handle the billiard tables—if the men were allowed to use them haphazard and just as they pleased, without being held responsible in any way, the chances were that they would be knocked to pieces in a very short time, and the thought occurred to me, "Why not treat this as we would in a private club? Whoever uses the table pays for it." There was this difference, however, that we could not afford to keep anyone to look after the tables and collect the payments. I believed that the men could be trusted in the matter, and therefore had some little printed slips made up in pads of one hundred, and instructions were issued that for every game the man who used the tables was to fill in his name on the slip and deposit it in the box provided for that purpose. These slips were collected once a week, and deductions made from the men's pay at the rate of 2 cents for each game, the loser of the game paying for the game. The revenue derived from this source was kept separately, and used for the maintenance of the tables, and anything in excess applied to the reduction of the rent of the rooms.

The balance of the rooms on this floor were rented for a sufficient rental, such that taken in connection with the receipts from the billiard tables, the rooms practically cost the company not over $10 per month, and I have always considered this as one of the best investments the company ever made. It did much to get the men together and keep them out of saloons and from hanging around street corners, and acted as a leaven to materially raise the esprit de corps, with the result that the men felt that they were not working for a soulless corporation, who did not care a continental whether they were taken care of or not, or whether their work was made easy or light, but they did feel that the company had their interests at stake, and we frankly told them that we were doing all we could afford to do and a little more. We did not hide our receipts nor our expenses from them, but told them frankly what they were and just how we came out year by year, and as times picked up and the receipts increased, we were able to do a little more for them, and did not hesitate to do it. The men, feeling that the interest of the company was their in-

terest, worked to further that—they were polite and attentive to passengers, took care of ladies and children, helping them on and off the cars, and in fact worked as though they really did have a financial interest in the success of the company.

Another thing which we did was to help the men in the matter of uniforms. When I took hold of the company, the men wore about anything they pleased in the way of uniforms, the principal thing being a blue coat and cap, with the word "Conductor" on the latter, and as each man had his own ideas on the subject, the styles were anywhere from a steam road conductor to a farmer. Having been brought up myself to see men in the neat uniform of the navy, it certainly grated to see this slipshod condition. Feeling that it would be a hardship to the men to force them to buy a new uniform at once, I suggested that they appoint a committee of five to select cloth and style of uniform, and told them that I would get bids from the different tailors, and that they could select the tailor and I would have him make the bid on a cash basis, the company paying for the uniforms and the men paying the company at the rate of $1 a week for the men having full pay, and a proportionately less amount for those receiving partial pay. In this way the men were able to get the benefit of a spot cash payment, which saved them about $2 on the cost of a uniform.

I found this committee to work well in the matter, and suggested to the men that they keep this committee or elect another to confer at any time when any points came up that seemed to need talking over. The only point that ever came up subsequently on which the committee needed to act was when the men in the winter time wanted to give a ball, and wanted to know what could be done in the way of taking their guests home when the ball was over, this being about 3 o'clock in the morning, after the cars had stopped running. This we readily fixed by telling the men that if they were willing to run the cars, the engines would be started up in the power house in time for them, and they could take their guests home without charge. In the summer time we also gave the men an outing, in the shape of a trolley ride with decorated cars, and let them invite their wives and sweethearts. After some two or three years union men from other cities came to our road and tried to interest our men in forming a union. The men promptly told these emissaries that there was no need of their joining anything of the kind, that they had all the union they wanted in their own club room, free, and I rather gathered from what leaked out subsequently that these representatives thought it advisable to leave the city on the first train, and it did not matter particularly where that train was going.

Too much care cannot be used in the selection of employees for this class of road; for the manager, it is almost like taking a man into his own family. Good men can be obtained, and therefore it is poor policy to take anyone who comes along and applies for a place. There is no point on which a manager needs to exercise more strictness than on this. Reference should not only be required, but should be examined into carefully, not necessarily by the manager himself, but by one of his aids, who reports on what he finds out of the man's past career, his habits, manners and customs, and the reasons why he is out of a place, or wants to leave his present place. We made it a rule never to take a man over thirty-five years of age, and for a motorman one of the requirements was that he should be a good mechanic or stationary engineer, and as vacancies were of infrequent occurrence on our road, we were able to hold to these requirements very strictly. When men were selected they were put through a course of training, motormen being sent for two weeks to work in the power house, followed by two weeks in the repair shops, then a week's instruction in operating cars, after which they were required to pass a written examination.

The training of the conductor, while not so thorough as this, was still sufficient to ground him in his duties before he was allowed to take a car, and he also was required to pass a written examination before he was accepted. Men coming in in this way were placed on the extra list, and were given a regular run in order of seniority.

Finally, I believe this class of roads can be made to pay if they are treated as has been indicated in this article. Each individual problem must be worked out, but in general it may be said that, given good equipment and good track kept up in first-class condition, a good manager who will show people that it is working not only for the interests of the company, but for their interests, and who can secure the co-operation of the employees, will make a road of this class pay.

Extension of the Plant of the Worcester Consolidated Street Railway

The Worcester Consolidated Street Railway is located in a thriving business town where the opportunities for a successful street railway are unusually good. Not only is the local traffic considerable and uniform, the cars being well filled on all the lines at all hours of the day, but connections are made with a large number of suburban lines. Among these are the Worcester & Webster, Worcester, Boylston & Clinton, Worcester & Leicester, and a half dozen other roads which connect with Fitchburg, Hudson, Leominster, Grafton, Oxford, Webster, Leicester and most of the principal towns and villages of Central New England. Through transfer systems and arrangements for joint use of tracks the road has been placed in a unique position, practically controlling the largest mileage, without exception, in New England, although its own tracks cover only about 65 miles.

Several of the neighboring roads have recently been acquired by a syndicate, and the question of consolidating the different suburban power stations has arisen, with the result that in the immediate necessary extension of the Worcester plant provision is being made for such additional equipment as may be needed to operate not only the Worcester street railway lines, but all the combined suburban roads. The power plant necessary for this immense system will be, with the exception of those controlled by the Boston Elevated Railway Company, the largest in New England.

The Worcester roads are all practically concentrated within the city limits, with the exception of the Worcester, Grafton Center and North Grafton line, which is also a part of the consolidated system. An average load of seventy double-truck cars is carried for about eighteen hours summer and winter, and the power-station output, under the same conditions, amounts to about 1250 hp. This is increased somewhat in the early morning and late afternoon hours, but the daily load factor is very high. The maximum current (exclusive of snow storms, etc.) is on a summer afternoon, say during a ball game, and sometimes rises to 3600 amps.

The power plant is located in the southern part of the city, near Webster Square, within 100 ft. of the Blackstone River, which furnishes an ample supply of excellent water the year round for both boiler feed and condensing purposes. A side track from the Boston & Albany Railroad leads to sheds alongside the boiler room, where capacity

for a month's supply of coal is provided. The building is of steel construction throughout, with light brick walls, the shaft center lines and boiler fronts being parallel and at right angles to the roof trusses, which are parallel with the gable ends. The extension, which is at the southern end, is being built without disturbing any of the existing construction. The present plant is 100 ft. wide and 120 ft. long, divided near the middle of its length by a 12-in. brick wall with only two doors, one at the end and one between the two batteries of boilers. The west wall abuts on the sidewalk, but there is ample room in every other direction, there being five acres of land in the property. At the northwest end of the engine room is the office of the superintendent, which is elevated about 12 ft. above the floor, giving a good view from the desk of every engine and generator. There are two monitors extending the entire length of the roof, one over the center of the engine room and one over the steam leaders above the boilers. The stack is steel, 100 ft. high, and rises from within the boiler room. The engine room floor is of latticed iron bars 10 ft. above the basement floor, so that the heating and condensing apparatus, piping, etc., are constantly in sight of the engineers. Each valve on the basement piping is connected with stands and rods, so as to be operated from the engine room floor.

The equipment consists of twelve horizontal, tubular boilers of 200 hp each, set in two batteries of nine and three units each; four 500-kw and one 850-kw generating sets, the four being belted, and the larger set direct coupled. The engines are all vertical, cross-compound condensing, built by the Lake Erie Engineering Works. The generators are of General Electric make. Most of this equipment was installed about seven years ago, and the generators especially are somewhat antiquated. In spite of this fact, however, the plant has run continuously for the seven years without a breakdown, and during that time has not been operating non-condensing for a single hour. The 850-kw unit has been running practically without a stop twenty-four hours daily for two years.

The condensing plant consists of a 500-hp Goubert feedwater heater and Worthington horizontal duplex independent jet condenser. A box crane rated at 8 tons, but frequently used for 30,000 lbs., and operated by hand, runs over the engine room. A 118-hp General Electric booster outfit, direct connected, is used for the "Lake line," raising the potential to about 650 volts, for transmission to the furthest distant point of the whole system, at Lake Quinsigamond, which is about 9½ miles from the plant.

The piping is arranged in duplicate for security against breakdown. Each of the first nine boilers is connected through a square bend to a T looking upward. From the run of the T a straight pipe leads to one header, and the other header is connected to the outlet of the T by a U bend having a valve at its highest point. The boiler mains are 6 ins., the two headers 12 ins. The last three boilers, which have only recently been installed, are each connected through a 6-in. long bend to an 8-in. header, from which two 8-in. U bends lead, one to each of the main headers. Steam to the engines is taken from Ts on the header through long sweep bends to the engines. No separators are used. The drips from the steam mains and headers are returned through traps to the boilers. These will eventually be superseded by some form of gravity return system. The engines exhaust into one 16-in. main, to which the condensers are connected, so that any condenser may be used on any engine. Neither mechanical draft nor economizers are used. The efficiency of the station as a whole has been moderately high, as compared with that of similar plants with more modern apparatus, but the operating expense per car mile has been low, and an average evaporation by the boilers of nearly 10 lbs. of water per pound of coal, with 170 degs. as the temperature of feed, is often reached, although they have been driven beyond their rated capacity.

The addition to the station will be 100 ft. in width and 90 ft. long, and will be of the same general construction as the existing portion. A broad monitor roof will be built over the engine room, which will consist of two bays 30 ft. and 16 ft. wide, respectively. The center bay, which is to contain the main engine, will measure 43 ft. from floor to bottom of roof girders, and will be surmounted by a 23-ton crane built by the Wrought Iron Bridge Company of Canton, Ohio. The smaller bay will have a 5-ton crane under a pitch roof. The boiler room, on the eastern side of the addition, will be an extension of the existing boiler room, and will permit of the installation of nine new boilers, making twenty-one in all. This room is 44 ft. wide and 16 ft. high to the lowest portion of the trusses. The roof is pitched up to a height of 38 ft. at the 12-in. dividing wall between boiler and engine rooms. The side walls of the addition are merely for filling in the steel work and are 12 ins. thick. The roofing is the H. W. Johns Manufacturing Company's asbestos paper; the flooring, granolithic on I beams and brick arches. There will be no basement, properly speaking, the condensers, etc., being planned to rest on the main floor, while the engine cylinders will be reached from this floor by a winding staircase. There will be a low, studded basement room under the westerly bay of the engine room, the purpose of which will be mentioned later. The main engine bay will be of sufficient size to contain two units of the size of the one now being installed. There will be space also for an additional 150-kw, direct-connected booster, which will become necessary if the plant is used to operate distant suburban lines.

The main floor of the smaller bay in the engine room is strengthened to support several three-phase rotary converters, which would in this case be required. The basement under would be ventilated by cone fans for the proper reception of step-up transformers. The rotaries would then take direct current at 550 volts from the main generators and deliver alternating current probably at not over 500 volts to the transformers. Here it would be raised to something above 2000 volts, the precise potential not having yet been calculated, and transmitted to various outlying sub-stations, where other rotaries would transform it to direct current for street railway use. All this is, of course, a matter of future probability, no transmission apparatus having been contemplated in the present stage of equipment.

The immediate extension for which the building has been thus enlarged consists of a 1600-kw, direct-connected generating set, which will be erected in October. The engine, which is being built by the International Power Company, of Providence, R. I., is a vertical cross compound, running at 100 r. p. m. The cylinder diameters are 32 ins. and 66 ins. respectively; the stroke, 48 ins. It will be the largest engine of its type in the country, with the exception of that recently purchased by the Boston Elevated Railway Company. It is of special design throughout, the novel features originating both with the builders and the railway company, many of the points being specified by Mr. McKee, the chief engineer of the plant. The high-pressure cylinder will be steam jacketed over the whole of its surface, the low-pressure cylinder on the heads only. A live steam reheater will be used between the cylinders. Lever throttles and lever by-pass valves will be used throughout, the general construction being closely in accordance with marine practice. A by-pass from the

main steam supply will be run to both sides of the low-pressure cylinder beneath the inlet valve.

The foundation for the engine will measure 35 ft. 8 ins. x 22 ft. at the top, and will be 13 ft. deep. The sub-soil is of first-rate quality for a footing, and the exposed work will be of Portland cement and broken stone concrete. The fly-wheel is 18 ft. in diameter and weighs 60 tons. The height from floor line to top of engine is 27 ft. 2 ins., so that a man standing on top of one of the cylinders could almost reach the roof girders. The shaft is of steel, solid, 20 ins. in diameter. The low-pressure cylinder is cast by a new method, which has been entirely successful. The shell and chest were made in three parts, the dividing lines being near the heads. The faces of these three parts were then machined, packed with very thin copper gaskets and securely bolted together. They have not been taken apart since, nor is it expected that they will be. The machining, including boring, facing and drilling, has been done on the three castings at once. The reason for so casting the cylinder was to provide for repairing a possible breakdown without getting a new cylinder. Should a head blow out taking a piece of the body flange with it, as it sometimes does in the power plants, the broken casting could be replaced in a short time by a new one made from the same pattern and machined to templates, and the new piece could be bolted in while the engine was in place on its frame.

Another unique feature is the valve motion. This, instead of being operated from spur gearing, as is usual in this class of engines, is actuated from two eccentrics set on the main shaft, one on the center and one on the quarter. The eccentrics transmit the motion to an auxiliary shaft, to which the rods are connected as in ordinary practice. As the rods are of extreme length, there will be no trouble occasioned by their angular displacement during rotation. The valves are of the endwise gridiron type, conforming in general design to the standard form of the old Green-Wheelock engines, and the clearance has been reduced by their use to less than 3 per cent. The main bearings are 20 ins. x 36 ins., and the generator outboard bearing 16 ins. x 32 ins. These are of the shell type, with water jackets. A small steam pump will maintain a gravity tank flow, or forced flow, if necessary, around each bearing piece. The bearing caps, instead of being fastened to the bases with stud bolts, will be connected with long T end bolts, the Ts setting in slots in the bases, which can be reached from the outside. This will render it quite easy to remove and replace the caps and fill the shells. The oiling will all be done mechanically, as it is in the present station. A supply tank will be located near the roof and a receiving tank in the basement. The oil will flow from the supply tank to the bearings, the regulation being by hand, and thence to the receiving tank. A small pump will take it from the receiving tank through a filter and force it to the supply tank again. A connection from a supply barrel will be made to the pipe between the pump and the filter. A Holly gravity drip system, soon to be installed, will carry all the live steam drips to a receiving tank, into which the low pressure drains from heaters, etc., will be brought. A small reducing valve blowing high-pressure steam into the heaters will give the required upward velocity to the condensation, which will thus be carried above the water level in the boilers to a supply tank, from which the return boiler feed will be through check valves to the blow-off pipes inside the cocks. This system will be entirely automatic and will be in continual operation except when a boiler is being blown off.

The exhaust from this engine will be carried to a 2000-hp Wainwright vertical heater of the "easy flow" type, especially designed for this plant. The heater body, which is 40 ins. in diameter, will be divided longitudinally into three compartments at the top and four at the bottom by webs, or fins, cast in one piece with the shell. The length of the body of the heater is 16 ft.; that of the tubes 124 ins. One hundred and fourteen $1\frac{1}{2}$-in. tubes are used, the total tube heating surface being 671 sq. ft., making a ratio of a little less than 3 hp to the square foot of heating surface. From the heater the exhaust will pass to the condenser, which is also of special design. This is a twin simplex beam vertical air pump and jet condenser, built by the Geo. F. Blake Manufacturing Company. The steam cylinder is 14 ins. in diameter; the water cylinder 35 ins. The stroke of both pistons is 21 ins. The floor space occupied is 7 ft. 4 ins. square, and the total height of the condenser from floor line to beams is 11 ft. 7 ins. The outfit is designed to give an even vacuum of $29\frac{1}{4}$ ins. of mercury with injection water at 70 degs. F. The water of the Blackstone River, which is to be used, will rarely rise more than 10 degs. above this temperature on the hottest days of summer. The vacuum maintained will, of course, have an important bearing on the economy of the engine as guaranteed by the builders. The contract calls for a steam consumption of the main engine, when operating at 125 lbs. steam pressure, not greater than $12\frac{1}{2}$ lbs. (dry) per i. h. p. per hour for any range of load between 1800 and 2500 hp. The vacuum under which this economy must be made has not been stated. With any practicable vacuum, however, so low a steam consumption at 125 lbs. steam pressure is almost unprecedented, and the result of the tests when they are made will be received with general interest. As the contract contains a forfeiture clause involving a heavy penalty for every 1/10 lb. of steam consumed in excess of the guaranteed rate, the engine will no doubt be a record breaker in its class. If the tests are made by weighing the exhaust steam condensed in a surface condenser and the indicators are accurate, the results ought to be authoritative.

The generator is one of the General Electric Company's multipolar railway type, running nominally at 550 volts at 100 r. p. m., and 10 per cent over compound. The machine has twenty-two poles. The distance across the field ring is 21 ft.; the armature is 164 ins. in diameter and the commutator 120 ins. The normal rating is 1600 kw, but provision is made for 25 per cent overload. The floor space occupied is 6 ft. x 21 ft., and the total height from base of bed to ring is 22 ft. The height from the top of the base is 14 ft. 6 ins. The machine will form a decided contrast to the old-fashioned octagonal field-ring generators now in the station. It will do well if it makes a better record. One of the commutators on a 500-kw generator which has been running steadily for seven years has only been turned off once in that time, and is to-day in almost perfect condition. The worst commutator of the lot is on a machine just opposite a doorway leading to the street. This has been turned down three times—about $\frac{1}{8}$ in. in all. All of this old equipment is working daily, the only perceptible defect being a slight weakening of the insulation.

The General Electric Company is building a switchboard for the new plant, which will take the place of the one now in use. Several of the present instruments will be utilized. The board will be constructed of black slate, in twenty panels; two for the boosters, six for the machines and twelve for the circuits. Should the developments already mentioned take place there will have to be added one machine panel, two or three feeder panels and several for the rotaries.

Instead of having connections separately from the positive, negative and equalizing wires to the board, a main negative bus is used, into which the negative wires of all

the machines are connected. By putting in the negative switch first the generators can be coupled in multiple. In other respects the board and wiring system will conform closely to standard railway practice.

Mention has been made of the rotaries and static transformers which may have to be installed very soon. The system will in this case be unique. The ordinary transmission plant uses alternating-current generators with step-up transformers if necessary and rotaries at the sub-station In this plant only direct-current machines will be used, and there will be four transformations: from direct to alternating current, then to high potential, then to low potential, and finally back to direct current. The reason for adopting such a system lies in the fact that a large amount of the equipment is already in place and that for best economy the large units must be used on the city lines. To fill these conditions direct current is a necessity and the loss by transformation through rotaries unavoidable.

Paris Exposition Notes

[*From Our Regular Correspondent.*]

It would be impossible to give in the pages of the Street Railway Journal, which it is possible to devote to the subject, even the briefest description of all the street railway exhibits at the Paris Exposition. The most important exhibits, however, have been mentioned, and readers of the paper may be certain that they have been able to acquire a knowledge of the street railway exhibits at the Exposition in this way much more readily and systematically, even if not so much in detail, than would have been possible by a visit to the Exposition itself. As already stated, the street railway exhibits are distributed around the Exposition in a dozen different places, so that it is almost impossible to locate them, and one would hardly be surprised at coming across some tramway exhibit in almost any section. Again, the delay, attributable principally to the Exposition authorities, in getting the exhibits in shape and under way, has added very much to the general confusion, and many exhibitors were glad to accept almost any space rather than to wait indefinitely until the space previously assigned them was ready for occupancy. This has added very much to the difficulty of locating many of the exhibits.

Mention has already been made that among the street railway exhibits American apparatus is predominant. Among those not previously described is that of the Lorain Steel Company, of Johnstown, Pa., and the Bullock Company, of Cincinnati, Ohio, who have a joint exhibit in the Electricity Building. Here the former company shows a number of Dupont trucks for single and double-truck cars, equipped with standard Steel motors. These motors range in size from 25 hp to 50 hp. A number of controllers, trolley poles, rheostats, etc., complete the exhibit. The Bullock space is devoted largely to Bullock generators. These are necessarily of the smaller sizes, but views are shown of 800-kw railway and power generators manufactured by the company. The American Steel & Wire Company has its largest exhibit in the mining section, where are shown samples of ore mined by the company, wires of steel, iron, brass, copper, aluminum, etc., varying in size, rail-bonds, etc. The Roebling Company has exhibits in both Electricity Building and in the Mining Building; the most conspicuous object in the former is a model of a conduit electric railway system, to show the method of connecting the feeders to the conductors; in the latter is shown a handsome model of the Brooklyn Bridge. The General Electric Company, in addition to the elaborate exhibits made by its representatives in Europe, and particularly by the French Thomson-Houston Company, has also an exhibit of its own in the Electricity Building. The feature of this exhibit is an elaborate model of its three factories made to the scale of 20 ft. to the inch. These models are constructed of sheet zinc and copper and beautifully colored, and every detail is reproduced. In addition, the company shows photographic views of its works and of some of the most important installations made in America and abroad. The Triumph Electric Company is making a joint exhibit with the Fay & Egan Company, of Cincinnati, Ohio. Part of this exhibit is located in the Electricity Building and part in Vincennes. The Triumph exhibit is of motors which run the woodworking machinery shown by the Fay & Egan Company. Among the other exhibits in the Electricity Building the visitor sees the switchboard appliances and overhead line material of the A. & J. M. Anderson Company, the commutator bars of the Billings & Spencer Company, the Van Wagoner & Williams Hardware Company, the Eureka Tempered Copper Works and the Forest City Electrical Company, the fuses of the Chase-Shawmut Company, the switchboard appliances of the Crouse-Hinds Company, the General Equipment Company, Zindars & Hunt and the Cutter Electric Manufacturing Company, the trolley appliances of the Central Union Brass Company, graphite brushes made by Joseph Dixon, Jersey City, N. J., specialties of the Creaghead Engineering Company, switches of the Falk Company, lightning arresters of the Garton-Daniels Company, fuses, overhead line appliances and heaters of the H. W. Johns Company, insulators of Fred. M. Locke, mica and micanite made by Eugene Munsell & Company, brushes of the Ohio Electric Specialty Company, New Process Rawhide pinions, fans of D. L. Bates & Brother, carbon brushes made by the Speer Carbon Company and the Partridge Carbon Company, raw hide pinions of Horsburgh & Scott, conduits of the Sprague Electric Company and American Vitrified Conduit Company, mica of the W. H. Sills Mica Company, Ward Leonard controllers, motors of the Jeffrey Manufacturing Company and the Crocker-Wheeler Electric Company, and wire of the Hazard Manufacturing Company and the Okonite Company.

In Class 27 of miscellaneous exhibits, in Electricity Building, are shown electric heaters made by the Consolidated Car Heating Company, Gold Car Heating Company and the American Electric Heating Corporation, and the measuring instruments of the Bristol Company, the Weston Electrical Instrument Company and Queen & Company.

Many of the American exhibitors in the tramway department have limited themselves to photographs or drawings of the apparatus made by them. This is particularly the case with the E. P. Allis Company, the American Car Sprinkler Company, the American Car Company, Babcock & Wilcox, Berlin Iron Bridge Company, Harold P. Brown, Chisholm & Moore Manufacturing Company, Christensen Engineering Company, Consolidated Car Fender Company, Hipwood-Barrett Car & Vehicle Fender Company, Leonhardt Wagon Manufacturing Company, Link Belt Engineering Company, J. R. McCardell Company, New York Car Wheel Works and Taunton Locomotive Manufacturing Company. Others, however, show models of their apparatus or samples. Among these, American rail-joints of different kinds are particularly prominent, especially those of the Continuous Rail Joint Company, the Weber Railway Joint Manufacturing Company and the Diamond State Steel Company. The Charles Scott Spring Company and the A. French Spring

Company both show sets of locomotive springs, while the Peckham Truck Company exhibits a beautiful set of models of the different types of Peckham truck. The American Street Railway Association has on exhibition a complete file of its transactions. McKee, Fuller & Company show a set of car wheels and axles, the Pressed Steel Car Company shows samples of its cars, trucks and bolsters, the Q. & C. Company of its tie plates, and the Safety Car Heating & Lighting Company is exhibiting its method of gas lighting.

Group IV. at the Paris Exposition comprises machinery, and, as is well known, the American exhibits in this department attracted widespread attention abroad, owing to the handsome showing made by American manufacturers. In this group are included steam appliances, prominent among which are engines of the E. P. Allis Company and of the Ball Engine Company, boilers of the Babcock & Wilcox Company and of the Clonbrock Steam Boiler Company, valves and pressure gages of the Crosby Steam Gage & Valve Company, injectors of the American Injector Company and Penberthy Injector Company, purifiers and filters of the Burt Manufacturing Company, steam separators of Joseph De-Rycke, lubricating graphite of the Joseph Dixon Crucible Company, governing and reducing valves of the Locke Regulating Company, valves, gages, injectors and lubricating devices of the Lunkenheimer Company, a feed-water heater of the Taunton Locomotive Manufacturing Company, valves, piping, etc., of the Walworth Manufacturing Company and of the Crane Company, feed-water heaters, pumps and condensers of the Wheeler Condenser & Engineering Company, pressure gages of the Bristol Company, valves and pumps of the Chapman Valve Manufacturing Company, a portable, automatic air compressor of the Christensen Engineering Company, conveying machinery of the Jeffrey Manufacturing Company, pumps and condensers of the Stilwell-Bierce & Smith-Vaile Company, flexible shaft appliances of the Stowe Manufacturing Company, exhaust fans and blowers of B. F. Sturtevant & Company, hydraulic jacks of the Watson-Stillman Company, pneumatic tools of the Chicago Pneumatic Tool Company and of the Q. & C. Company, corundum wheels of the Hamden Corundum Wheel Company, and machine tools of the Niles Tool Works Company and the Pond Machine Tool Company.

One of the most prominent electric railway exhibits at the Paris Exposition is the large electric locomotive, manufactured by the Allgemeine Elektricitäts Gesellschaft, of Berlin, and designed for hauling passengers and freight cars, as well as for switching purposes on heavy-service roads. It is constructed for a standard gage of 4 ft. 8½ ins. (1435 mm). The trolley and fixtures above the locomotive may be removed without trouble in case it is desired to use the locomotive as a car of a train. In that case the gears are also removed from the axles, so that the armatures do not revolve. The locomotive is capable of pulling a 300-ton train at a speed of 19 miles an hour, or 30 km per hour, on a level. The weight available for traction, which is equal to the total weight of the locomotive, is 24 tons; the maximum draw-bar pull at the start is 7900 lbs. (3600 kg). With the exception of the roof of the motorman's cab, the floor and the inner facing, the locomotive is constructed entirely of iron and steel. The wheel base is 8 ft. 2½ ins. (2500 mm), so that the locomotive can traverse the sharpest curves met with on railways. The wheels are 39.4 ins. (1000 mm) in diameter, and have wrought iron centers, with steel tires. The weight of the locomotive is carried on the two axles by means of elliptical springs.

The locomotive is equipped with a Westinghouse air brake, with independent motor compressor, and with hand brakes. Air whistles are used. The front and rear of the locomotives are made low, with sloping tops, to give an unobstructed view of the track from the cab, according to standard practice.

The trolley base extends along the entire length of the roof of the cab. The current is taken off by means of four sliding trolleys of special construction, which are pressed against the trolley wires by means of heavy springs. The style of trolley was adopted on account of the frequent changes of direction of travel which might be expected. In order to insure sufficient contact the manufacturers recommend a number of No. 0 (8 mm) trolley wires. The locomotive at Paris is fitted with three.

The locomotive is equipped with two type 800 V. B. (150 hp) motors, each geared to an axle at a 1 to 3 ratio.

In addition, this German company has on exhibition a three-phase 3000-kw generator with direct-coupled exciter, a pavilion lighted by Nernst lamps, a complete assortment of commutators, transformers, wattmeters, arc lamps, tramway equipment parts, photographs of installations, etc.

The German exhibits, on the whole, are exceedingly complete and elaborate, and reflect great credit on the German manufacturer. Among those which I have not previously described the exhibit of Felten & Guilleaume, of Carlswerk, deserves notice. In addition to the full line of bare and insulated wires, which this company shows, for electric light, power and miscellaneous electric service, the company is making quite an elaborate exhibit of copper rail-bonds. Both the Electricitäts Actiengesellschaft, formerly Schuckert & Company, of Nuremburg, and the Helios Company, of Cologne, make elaborate exhibits. The latter shows quite an amount of tramway apparatus including railway motors of different sizes. Outside of Germany, the principal Continental firms exhibiting tramway apparatus are Ganz & Company, of Buda-Pest, and the Société Anonyme d'Electricité & Hydraulique, of Charlevoix, both of whom have elaborate exhibits. The latter shows direct-connected units of 1000-hp three-phase, 500-hp monophase, 200-hp direct-current motors, etc., in addition to its standard street railway equipment.

Most of the English exhibits which are of interest to tramway managers will be found in the Electricity Building, although there are a few in Vincennes. Among the latter are the Westinghouse exhibits, already mentioned in previous issues. The Mossberg Roller Bearings Company shows journals fitted with its well known bearings. In the Electricity Building, however, will be found the greater part of the British exhibits, including those of the British Insulated Wire Company, Callender's Cable & Construction Company and W. T. Glover, showing cables and wires for electrical transmission purposes. British industries are also well represented by the exhibit of Mather & Platt, who have a direct-current unit in the Exposition power station; the Chloride Electrical Storage Syndicate and the Electrical Power Storage Company both showing accumulators, and James White, of Glasgow, who is exhibiting a fine line of scientific and measuring instruments. R. W. Blackwell & Company, Ltd., also exhibit a full line of the many devices and appliances for which they are selling agents, and supplied a large proportion of the material for the third-rail Exposition Railway. In the Suffren power station of the Exposition one of the largest engines was supplied by Willans & Robinson. This engine is of the well-known Willans type, is of 2400 rated hp, and is direct connected to a 1340-kw direct-current 500-volt generator, built by Siemens Bros. With the possible exception of one German engine, which is of about equal capacity, it is the largest engine in either of the two electrical stations at the Exposition.

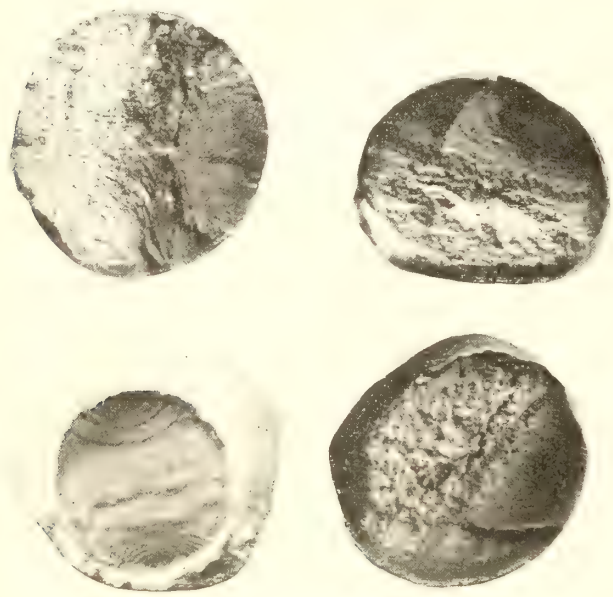
CORRESPONDENCE

Breaking of Copper Trolley Wire

Societa Generale Italiana Edison di Elettricita,
Milan, Italy, July 11, 1900.

Editors Street Railway Journal:

Where the copper trolley wire on our system has broken we have noticed the constancy of certain marked characteristics that we think may be of some interest to your readers. The broken surface is never homogeneous, but consists of one part showing a fresh break, and one or two other parts showing a series of concentric zones of brown



SECTIONS OF TROLLEY WIRE

(Enlarged about five times actual size)

oxide. The photographs annexed represent some of these surfaces.

It would seem from these sections that the breaking is not due to a sudden strain or to a reduction of the area, but occurs gradually and during a comparatively long space of time.

It would be interesting to know if other observations of this kind have been made on other roads, and if any investigations have been made to determine the cause of this initial weakening of the wire. Guido Semenza.

Polyphase Distribution for Electric Railways

Denver, Col., Aug. 10, 1900.

Editors Street Railway Journal:

Dr. Louis Bell has, in this month's Street Railway Journal, what appears to me to be a very timely word of caution against the extravagant application of the three-phase method of distribution for railways. To be in fashion some railway companies are evidently using it when the ordinary well known and much cheaper methods are available. Electrical distribution for railways with direct current and the ordinary standard machinery has by no means reached its limit, and although railway companies are generally suffering for higher voltage, their engineers appear to have overlooked the fact that they all have it within easy reach.

The present and almost universally used method of distribution *is all wrong*. High voltage in the congested districts and low in the suburbs is the rule. It should be the reverse. Running motors down town in series is poor practice. It heats them, while running the cars in the suburbs under low voltage is very expensive. The heavy current used also heats the motors and is a severe drain on the supply. The time of the motorman and conductor is also squandered wastefully. On more than one road with which I am acquainted the total operating expenses could readily be reduced 20 per cent by changes in the circuit arrangements. The method I advocate is a three-wire compensating system. The ordinary generators are used, but coupled in Edison's three-wire way. Those on one side, which are to supply the congested districts, are arranged for, say 450 volts, while the other side, which supply the outskirts, are arranged for, say 650 volts. Such an arrangement would effect a great saving in copper and would come pretty near eliminating that great source of trouble—electrolysis. By speeding up in the suburbs four cars may take the place of five now running, and in some cases one-half of the number could be dispensed with. People living in the outskirts would probably be as well accommodated with a forty-minute service done in twenty minutes as with a half-hourly service, which requires thirty minutes to take them to business or home.

If it is desired to extend the roads to other towns, for instance, the ordinary motors may be used safely and have all of the advantages of a distribution at 1100 volts. This would require a double trolley, each to be in connection with the outside terminals of the three-wire system. The motors would be run in series. John C. Henry.

The Characteristics of a Successful Street Railway Manager

Neck o'Woods, N. Y., Aug. 11, 1900.

Editors Street Railway Journal:

I know that it is great temerity on my part to try to add to the words of yourself, Mr. Vreeland and John Smith, but "fools rush in, etc.," and this is my rush. I read your article on "Successful Managers" in the June number, because I always find something good in that department; I read Mr. Vreeland's article because he always says something worth listening to and has the happy faculty of winnowing the wheat from the chaff and baking it into good, plain, everyday bread (I hasten to say that this last sentence has no reference to *your* article!), and I read Mr. Smith's article because he seems to voice the opinions of that large portion of the human race that bears the same name, and therefore his article *ought* to carry weight.

When I had read and digested the three, I put all the qualifications into one pan of a scale and jumped into the other pan myself, and—like Mr. Smith—I *just* balanced them! That showed at once that there was something wrong somewhere, as I am *not* a "successful" manager; there was certainly short weight or count on the part of the qualifications, so I hunted for the missing ones, and found them as Paddy found the cellar door—"by their *not* being there."

You have all three missed two important qualifications of a "successful" manager—the available opportunity to display his ability and the power to grasp it. You see, it is not given to all of us to have the opportunity to take our little candle out from under the bushel and wave it in the sight of bankers and syndicates; with some of us blind fate sits on top of the basket with all her heft, and our little taper burns on—and out—in "innocuous desuetude"; then again there are times when she will kick the bushel over, yank out the light and wave it so high and wide that all plutocracy shall see it—and thus is made another success-

ful manager! No—the most important of the qualifications is the opportunity—the available opportunity. Shorn of this, the manager may be *capable*, but he will not be "successful" in the full meaning of the term. He may be all that you three artists have painted him; he may be capable in each and every one of the seven ways (Mr. Smith seems to think that there are only six), he may have proved those qualifications one by one and over and over, but until he gets the *opportunity* to *display* those seven managerial virtues, what shall it profit him? And Echo answers: "From twelve to eighteen hundred per year with a week's vacation to attend the A. S. R. A. convention, if it happens to be held near his town"! And Mr. Smith indorses every word that Echo says, and to prove it plays a sample tune on his own horn! This is a bad example, and—while I know that "comparisons are odious"—I am going to do the same thing—in another key.

You—Mr. Editor—have known me a long time and are pretty well acquainted with my railway career; you know that I have had a succession of small successes without a single failure to mar the dread monotony since my unhappy fate dumped me into the street railway business. You know that I can plead guilty to all of Mr. Vreeland's "seven virtues," even to "honesty," "diplomacy" and "horse sense"; you know that I know the street railway business from top to bottom and am still willing to learn, and yet I would hardly call myself a "successful" manager, because I have never had the opportunity to display these qualifications in any field large enough to attract attention to my work nor to redound very greatly to my credit or my financial benefit.

Now, I know that someone will say "Pshaw! The successful man—or manager—*makes* his opportunity." That is not true, and what is worse, it is not good sense. Opportunities are like poets, they are born and not made. It takes three things to make a successful manager; the capable man, the available opportunity and the ability to grasp it, and if they do not all come—and come together at the same time—well, there is "another good man gone wrong"!

So, Mr. Editor, if you do not feel convinced that I am right in both my arguments and my "terrible example," just you get some of those bankers and syndicates to turn loose a few fine, large opportunities and send them down this way, and I will soon prove to you and Mr. Vreeland (Mr. Smith does not need any proof on this point) that you both left out two very important qualifications!

Yours hopefully

BROWN, JONES AND ROBINSON.

The Car Hour Unit in Milwaukee

It will be remembered that at the last convention of the Street Railway Accountants' Association of America, H. C. Mackay, auditor of the Milwaukee Electric Railway & Light Company, made an able argument in favor of the use of the "car hour" instead of the "car mile" as a unit for comparing the results of operation. The "car hour" unit has also the indorsement of John I. Beggs, general manager of the company, and has been adopted by the company, as shown by the reproduction herewith of the company's daily earnings sheet. In this sheet the names of several of the divisions have been omitted to reduce the space required for the form.

This statement, as will be seen, gives a comparison of earnings by lines, together with a comparison of the service given to secure such earnings, and the effect of that service, and keeps the management thoroughly posted as to the service required.

An example is given in the form below, showing an increase in service of forty-five car hours, which has produced an excess revenue of $54. It has, however, reduced

the earnings per car hour from $2.20 to $2.10. Assuming the cost of operation to be $1.20 per hour, the result would be:

Year	Car Hours	Net Earnings
1900	450	$405.00
1899	405	405.00

Indicating that while the increased service has reduced the earnings per hour, the profit on the increased hours has made the net earnings equal.

Electric Express Company at Dayton

The Southern Ohio Express & Freight Company is now being organized at Dayton, Ohio, for the purpose of conducting the freight and express business on the electric lines centering at Dayton. The officials of the different electric railways centering at Dayton will be interested in the company, and it is said that James M. Randall, at present with Wells, Fargo & Company, will be general manager of the company. The capital stock of the company will be $100,000.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the Journal *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our news columns.

All matters intended for publication in the current issues must be received at our office not later than Wednesday of each week.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

Experience from visiting a large number of railway systems has shown that a pretty fair index of the care exercised in the maintenance of the entire road can be gained from the condition of the car house. While this is not always true, it is generally safe to conclude that where the car house is kept clean and light, and where the corners are not made the depository of worn-out parts and scrap, the line, as a whole, is kept in pretty fair condition. On the other hand, if the reverse is the case, slackness in management is generally present in other parts of the system. This is true not only because one part of the system is not likely to be better than the rest, but because the car house is to a certain extent the center of the maintenance department, and the microbes of trouble which develop outside on the road very often have their origin there. For instance, if a slovenly use of grease is permitted in the car house the repair men there soon look more like coal heavers than like mechanics, whose business it is to handle electrical machinery, and it is not strange if they should lack a certain pride in the maintenance in a cleanly condition of the apparatus under their care. Again, if dust and dirt are allowed to accumulate in the corners, they soon extend to the controllers and motors, and where there are miscellaneous piles of scrap and broken parts on the floor they often hide new supply parts and the tools used in car repairs. As a result the workman fails to find the tool he requires for the repair which he wishes to make, and often either neglects to make the repair entirely or uses an inferior substitute for the right article to save time. The ideal car house should not only be kept in good condition, but it should be so located that there is plenty of light from above and on the sides, and the light should enter the building in such a way that it is not cut off by a line of cars standing on the tracks. Where the structure is in the center of a crowded city, where natural light is not available, it is the best economy to use artificial illumination freely, as it is almost impossible to keep a dark car house in tidy condition. Eternal vigilance is the price of a low maintenance account, and a car house in good order is one of the most important factors in securing it.

* * * *

Another factor, however, is order and arrangement in the repair shop, and here also can often be found causes for a high repair bill. One of the most conspicuous of these causes is that there is no one person responsible for the tools used and there is no place to keep them when not in service. The time lost by workmen in searching for misplaced or lost tools will usually more than pay for a tool room and attendance to insure the return to the storeroom and keeping in proper order of the necessary tools used in repairs. Tools are lost and broken, and in order to save the first cost of the proper tools resort is made to all sorts of makeshifts, which involve loss in labor and the waste of good material. While it is true that a good workman does not blame poor work on the tools he employs, yet it is certain that better work can be produced where well kept tools suitable for their purposes are supplied. The large roads have learned by experience that these elements are vitally important essentials in bringing down the cost of repairs and in increasing the life of the equipment. In the smaller roads these matters are not so readily determined, but the cost of equipment repairs is high, and where the tool investment is small, the supply and labor investment is large for a given number of equipments maintained.

It has been found by several roads operating suburban and interurban lines that the powerful search-light beam from an arc headlight is of great benefit in running the cars at high speeds after dark. Such arcs are always supplied directly from the 500-volt circuits, by far the greater part of the power taken from the line for this purpose being wasted in dead resistance. By the use of the enclosed type of arc lamps from 80 volts to 100 volts can be usefully expended between the carbons. Enclosed arc lamps are

made for even higher voltages, some lamps used on 220-volt lighting circuits being designed to operate with as high as 150 volts or 160 volts between the carbons. It is difficult, however, to adjust the lamps so that they will operate successfully with such long arcs under the vibrations of car service, so that about 100 volts is all that can be usefully expended in the arc, the other 400, 450 or 500 volts, as the case may be, being wasted in the resistance. In an arc taking 6 amps. this means a waste of about 2½ kw or 3 kw, and any means of preventing this waste would remove a serious objection to the arc headlight. While this power can during a part of the year, be used to assist in heating the car by putting the headlight resistance in the car during the winter and outside of it in the summer, obviously the most useful application would be in the lighting of the car, as car lights and headlights are desired at the same time, summer or winter. If the car lights were wired in series with the arc headlight, in place of the usual resistance, they would be subjected to the fluctuations of the arc, and particularly to the jump of the current when the arc is struck by the closing of the carbons together on starting. The fluctuations of the enclosed arc are slight, and their effect upon a circuit with a large fall of voltage in series with the arc is still less, so that this factor would disturb the steadiness of the light of incandescent lamps less than the usual variations of trolley voltage. The jump of the current on striking the arc might, at first sight, appear to be a serious objection, but it must be remembered that even if the arc is short-circuited the lamps, normally burned at 450 volts, would only be getting 550 volts, not enough to burn them out very soon if of good quality and of low efficiency.

About two years ago one of the large Edison companies operating 80-volt enclosed arc lamps on its 115-volt mains tried the experiment of putting in incandescent lamps for the series resistance to absorb the 30 volts or 35 volts difference between the line voltage and that of the arc. These lamps, of course, got a tremendous rise of voltage when the arc was momentarily short-circuited by the closing together of the carbons. They operated satisfactorily, however, for some time; but, being simply used to illuminate a street corner sign, the arc itself giving all the light that was wanted, their value was small and their use was not extended. In street railway work, however, the 2500 watts or 3000 watts thrown away in series with an arc headlight would serve to light thirty or forty 16-cp lamps, enough to make even the longest double-truck car a blaze of illumination. This could be done without taking any current for the incandescent lamps, the waste of the headlight being used solely for this purpose. The wiring could easily be arranged to substitute a resistance for the arc light during those times when it is desirable to shut off the arc on meeting other cars, etc. It would be interesting to know whether this experiment has been tried, and if so, with what results.

Street Railway Consolidation.

Some time since we gave a brief investigation of the advantages to be derived from consolidating small roads into connecting systems, viewing the matter mainly from the operating side. The advantages gained in the way of cheaper motive power, increased traffic from other connections, and the possible advantage to be gained from consolidating power systems—all these causes operate to insure very material economies. There is, however, another side to the matter, viz: The gains to be made from consolidation in the matter of more general expenses than those to which we previously referred. Whatever views may be held with respect to the effect of consolidations broadly considered in the public interest, all political economists seem to be pretty well united for once upon the following proposition: That human energy misapplied, or applied at an economic disadvantage, is a loss to the community. Consequently there seems to be a general concurrence of opinion that as regards consolidations, viewed in their most general aspect, those changes due to consolidation which avoid needless expense and apply, on the whole, the energy of the organization more efficiently thereby, are, to both public and private interests, thoroughly beneficial.

A very brief investigation of the facts regarding the small street railways of the country will show that not only can consolidation improve their condition in the ways heretofore described, but more particularly by means of lessening unnecessary and wasteful expenditures, and enabling the general business of the consolidated companies to be carried on more economcially than would otherwise be the case.

Without endeavoring to analyze too closely the nature of these affairs, there are three directions in which consolidations are able to make a very remarkable improvement in the economic conditions surrounding such enterprises. These three are, economy in fixed charges, economy in administration, and economy in maintenance and repairs. Taking these up in order, an item which is apparent at the first glance is the advantage of large consolidated interests in the matter of funded indebtedness. When a group of roads pools its issues, and comes under a consolidated management, there is, in nearly every case, back of the enterprise financial support of the most solid character. Now, *per se*, such a backing may be no more responsible or of any higher integrity than the interests back of the small individual enterprises; but, nevertheless, it is a fact that the large interests represented in the case of consolidation can and do secure funds at a very materially lower interest rate than could possibly be obtained by the component parts of the enterprise.

There are still a good many small roads whose funded debt bears 6 per cent interest. They may be perfectly solvent and well administered, but under such general conditions that any further issue of bonds, for purposes the most legitimate, would practically have to be made at the same rate. A very large number of roads have of late been able to secure funds at 5 per cent, but below this rate only the biggest and solidest enterprises have, as yet, been able to go. Once let a group of small roads be consolidated or put into a single coherent solidly backed enterprise, and it becomes possible to secure further capital for proper administration, at a rate ½ per cent to 1 per cent better than could possibly be realized by the roads independently.

Now, street railways at the present time are operated on an average margin of profit so small, that saving of interest on funded debt is an advantage not lightly to be put aside. The last report of the Railroad Commissioners of

Massachusetts gives a vast amount of detailed information regarding the financial status of the various roads throughout the State. The average street railway in Massachusetts is, from necessity, rather conservatively capitalized and rather economically managed. Yet the report of the Railroad Commissioners shows that out of 116 companies doing business in the State, only fifty-four last year paid dividends; while the remaining sixty-two, of which thirty-eight had been in operation more than a full year, had paid no dividends whatever. This indicates that not a few roads, even in a time of more than average prosperity, are staggering along under the unpleasant burden of funded indebtedness.

For example, one small road which carried last year more than three-quarters of a million passengers, came out of the game $2.51 to the bad. Even a small saving in interest on its funded debt would have made a much pleasanter looking balance sheet, although it might not, and would not, have justified the payment of a dividend. Another road that shall be nameless here paid a dividend out of a surplus providentially secured the previous year, although it was blessed during the current twelve months with a visible net income of only $152.34. This statement is merely given to indicate that not all even of the fifty-four companies in Massachusetts which paid dividends had actually earned them during the current year. The long and short of it is that the margin of profit is so small in the operation of the average—not the favored—street railway, that the saving to be secured from the better financial standing, which, on the whole, comes from wise consolidation, is really a very valuable asset. The investor has a feeling of security in a carefully consolidated system that he never has with respect to most of the individual parts of which it is composed.

If this were the only gain to be secured by consolidating there might not be, in many cases, sufficient reason for such a step. But in the general administration of small roads there are necessary expenses which may be materially diminished when a group of roads is put under a united management. For instance, the items of superintendence and clerk hire, in other words, the general office expenses, are very materially reduced by a consolidation of management. In many cases the possible saving might only be 1 or 2 per cent of the operating expenses, but, such as it is, the economy is clear gain. With one set of general officers and an economically administered clerical department, a group of roads can generally be assured of enough saving to make a very perceptible change in the balance sheet.

But this is by no means the most important gain in administration which can be thus effected. Two of the items of general expense in street railway operations, not always appreciated by the general public but painfully evident to those in the business, are legal expenses and insurance. A strong consolidation gains in the former item, not only directly, but indirectly, on account of the considerably smaller probability of a certain class of legal actions being brought to a damaging termination. Every one engaged in the business of transportation sooner or later runs across litigious individuals who succeed in making themselves very disagreeable and sometimes very expensive to the enterprise in which he is concerned.

The general legal department can take care of such cases more cheaply and efficiently than is possible in the case of the small individual road, operating only in the district in which the action may chance to be brought. Legal expense is, however, as a rule, not a considerable portion of the operating expenses; although it not infrequently rises to half a per cent or more. A much more serious matter is the insurance, which is more or less involved in the question of legal expense in very many cases, inasmuch as a large part of the insurance expense is due to accident and liability insurance of one kind or another. A glance through the report just referred to shows that it is not uncommon to find as high as 5 or 6 per cent of the total operating expense charged to insurance. This is a very considerable amount and one in which a material saving would be highly desirable. Of course it is an open question as to how far it is economical for street railways to carry all or a part of their legitimate insurance charges, but the policy of at least partial self insurance is one often carried out successfully, and, in the case of large consolidated enterprises, a chance for gain of this kind is much greater than among roads considered individually.

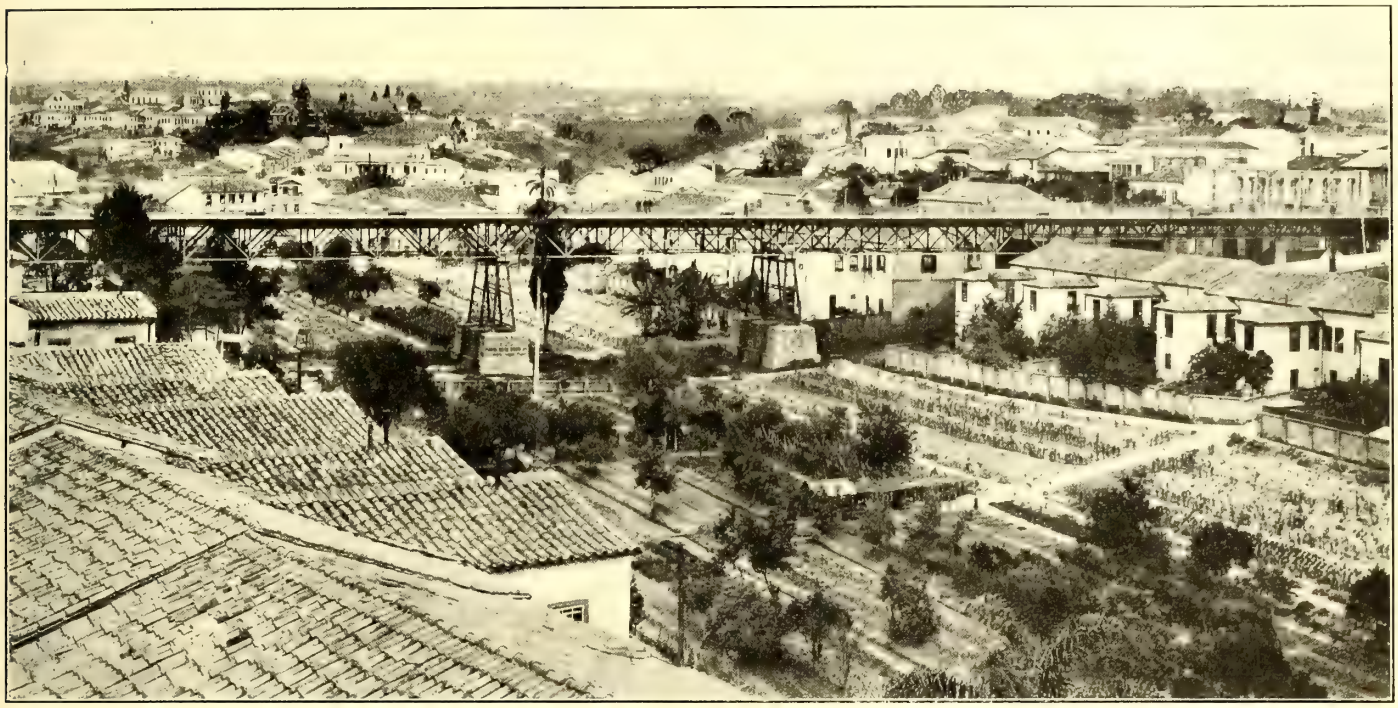
Closely allied to the question of general expense, yet in some features related to operating cost, is the matter of such organization as will secure economical buying, and careful and searching book-keeping. It is rather difficult for a small road in which one or two men are charged with a great variety of duties by way of superintendence, either to keep as close track of the books or to buy as advantageously as is easily possible when there is a regular accounting, auditing and purchasing department. Much of the advantage in consolidation as respects funded indebtedness also applies to the uniting of current purchases of material. On the whole, a large and solidly backed organization can buy cheaper and on better terms, and with more effective competition, than a small road operated as an individual and with comparatively limited resources. It will be very difficult indeed to estimate the amount of possible or probable saving due to this cause, but those practically in the business not infrequently have occasion to realize it.

In the department of operation and maintenance there is likewise a chance for very material economy. As a rule, large roads own and operate their own repair shops, and do much other miscellaneous work of a similar character, for which the necessary equipment is a considerable item of expense. Small roads, as a rule, have not this advantage, and consequently many items of maintenance fall most heavily upon those least able to bear them. The moment a consolidation takes place all the parties to it have the advantage of the aggregated facilities for repairs and maintenance.

The sum total of the items which we have enumerated as favorably affected by a union of roads under a single, strong management, is of amount not easy to estimate exactly on account of the varying conditions. It will generally, however, be as much as 10 per cent of the total operating expense, sometimes as high as 15 per cent. The possible savings from this amount are certainly large enough to make an essential difference in the year's balance sheet of the average road. It is worth noting that the savings here enumerated are practically dependent upon organic consolidation, while those to which we directed attention a few months ago can be, in part at least, secured through friendly affiliation.

The Sao Paulo Tramway, Light and Power Company

In the issue of July, 1899, the STREET RAILWAY JOURNAL announced the formation of the Sao Paulo Tramway, Light & Power Company, Ltd., and gave a short description of its plans. Recent reports from Brazil show that the undertaking is progressing very favorably. This company, it will be remembered, was organized under the laws of the Dominion of Canada, early in the year 1899, for the purpose of constructing and operating a combined electric light, power and street railway system in the city of Sao Paulo, State of Sao Paulo, Brazil, the concessions granted to F. A. Gualco and A. de Souza for these purposes having been assigned to the company. The construction work was commenced about the 1st of July, 1899.



GENERAL VIEW OF SAO PAULO

The city of Sao Paulo has 260,000 inhabitants according to a census just completed. In addition to a large area of the city proper, there are several suburbs to which the company proposes to extend its lines. The city is substantially constructed, possessing many fine buildings, and is well provided with schools for general education, as well as for higher college work, including normal and law schools. The streets are well paved, a very large amount of money having been expended for this purpose within the last few years. A first-class waterworks system supplies all portions of the city, and all sections are well provided with sewers. The city is lighted with gas at the present time, and in a manner fully as satisfactory as that of any city of Europe or in this country, where gas lighting is still in vogue. The street lighting, waterworks and sewers are under the control of the State authorities.

The city of Sao Paulo is located upon a high plateau, about 2300 ft. above the sea level, and on account of climatic conditions, is noted for its healthfulness as compared with other Brazilian cities. The infectious diseases which are so prevalent in the seacoast cities are practically unknown at Sao Paulo, and it is very rare indeed that an isolated case is brought into the city from the seacoast. In consequence of its healthfulness the city of Sao Paulo is the manufacturing center of Southern Brazil, and one of the most important cities in the Republic in this respect. The manufactures are very diversified, consisting of bags, shoes, sugar, beer, cotton and woolen cloths, sacking for coffee bags, flour, brick, tile, coffee, machinery and other products.

A large amount of power is used in the city, now produced by steam, aggregating at least 4000 hp. The power plants are of various sizes, from 500 hp down, of which 1000 hp consists of motors, ranging from 5 hp to 25 hp. On account of the price of coal, the cost of steam power is quite high, and the consumers are very generally pleased at the prospect of securing a cheaper and better form of motive power.

The hydraulic plant is situated at Parnahyba, 21 miles from Sao Paulo, on the River Tiete. The initial installation will consist of three turbines of about 2000-hp capacity, directly connected to alternating-current generators of the three-phase type, with necessary step-up transformers, and high and low-tension switchboards. The building is being constructed so that a fourth turbine and generator can be installed at a later date if desired. As shown by the dotted lines on the general plan of power development the capacity can be doubled should occasion

VIEW OF DAM IN COURSE OF CONSTRUCTION

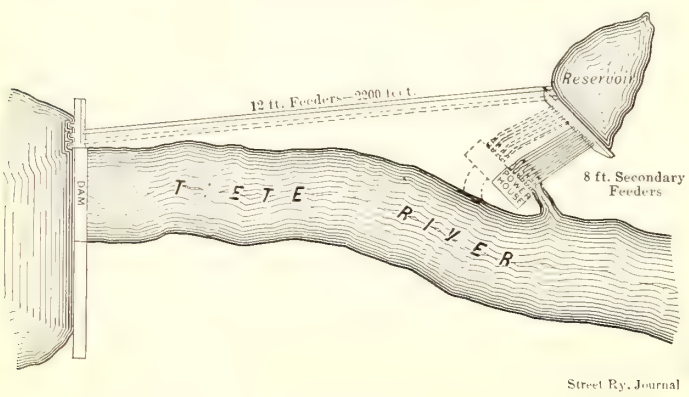
arise. The hydraulic plant consists of two dams, the larger crossing the River Tiete about 35 ft. in the clear height, and about 750 ft. long on the crest, constructed of rubble granite masonry, founded on solid ledge. The illustration shows the dam in course of construction. It will form a large storage reservoir of an average width of 660 ft., and a length of 4 miles to 5 miles in the main course of the river. In addition to this, there are several lateral branches, following up the course of streams emptying into the main river for long distances, and covering large areas, so that the combined surface area of the reservoir will probably exceed 600 acres, thus affording enormous storage capacity. The water will be conveyed from the dam to a small reservoir through a steel tube 12 ft. in diameter, by 2200 ft. in length. This tube will be supported every 10 ft. by steel saddles, similar to the one shown in the illustration. The irregularities in the surface of the ground are overcome by lengthening the uprights of these saddles, and making cuts through the hills. The view of the masonry foundations—which are made of granite rubble, capped with cement—shows the large amount of work required on this main feeder construction. To provide for changes in temperature three expansion joints of the type shown will be placed in this tube. These joints will allow quite a change of length in the pipe, the rubber gaskets effectually preventing leakage. The small reservoir, at a distance of 2200 ft. from the main dam, is formed by a small dam about 165 ft. long by 50 ft. high, across a ravine. The water is led to the turbines from this small dam through steel feeder-tubes, about 8 ft. in diameter and 178 ft. in length. Two small feeders, of about 3 ft. diameter, are provided for operating the exciter turbines. The head of water at the turbines will be about 75 ft.

MASONRY FOUNDATION FOR MAIN FEEDER TUBE

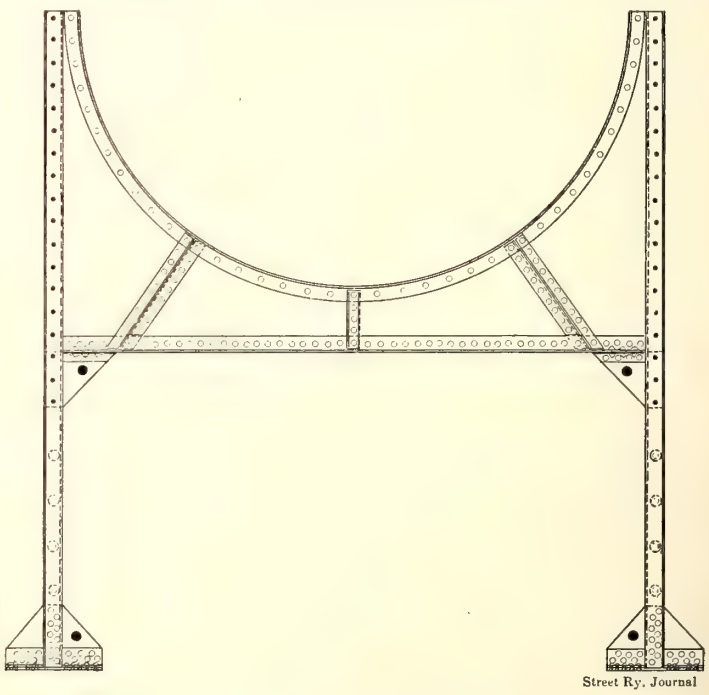
When completed there will be installed in the power house four horizontal twin turbines of a rated capacity of 1800 hp, direct connected to alternating-current generators; and two 150-hp turbines, connected to 100-kw exciters. The hydraulic apparatus is of the Victor type, from the Stilwell-Bierce and Smith-Vaile Company, and the electrical equipment is furnished by the General Electric Company. The alternating current is transformed by twelve step-up transformers of a total maximum capacity of 5600 kw to the line potential of 25,000 volts. The transformers are of the air blast type, the ventilating fans being made by the Buffalo Forge Company. For the operation of the apparatus and the control of the current, an extensive switchboard is provided, consisting of two high-tension line panels, one ground detector panel, four generator panels, two exciter panels, four high-tension and four low-tension transformer panels, and two totalizing panels. In both the main power station at Parnahyba and the sub-station in Sao Paulo the high-tension switchboards are placed on a gallery near the entrance for the transmission line. The other switchboards are placed on the main floor. All high-tension wiring is thus kept away from the low-tension circuits, the latter being, in general, placed under the floor in terra cotta ducts. The power station building is fireproof, built of concrete and iron, provided with traveling cranes, and machine shop for the repair of apparatus.

A substantial and comfortable dwelling house has been constructed, near the power station, for the accommodation of the employees of the company, who are to be stationed at Parnahyba. A telephone system connecting the Parnahyba station with the central one in Sao Paulo, and also connecting the various car houses, shops and offices of the company in the city, will be installed.

From careful measurements of the flow of water made last summer at the low water season, it was found that



GENERAL PLAN OF POWER DEVELOPMENT

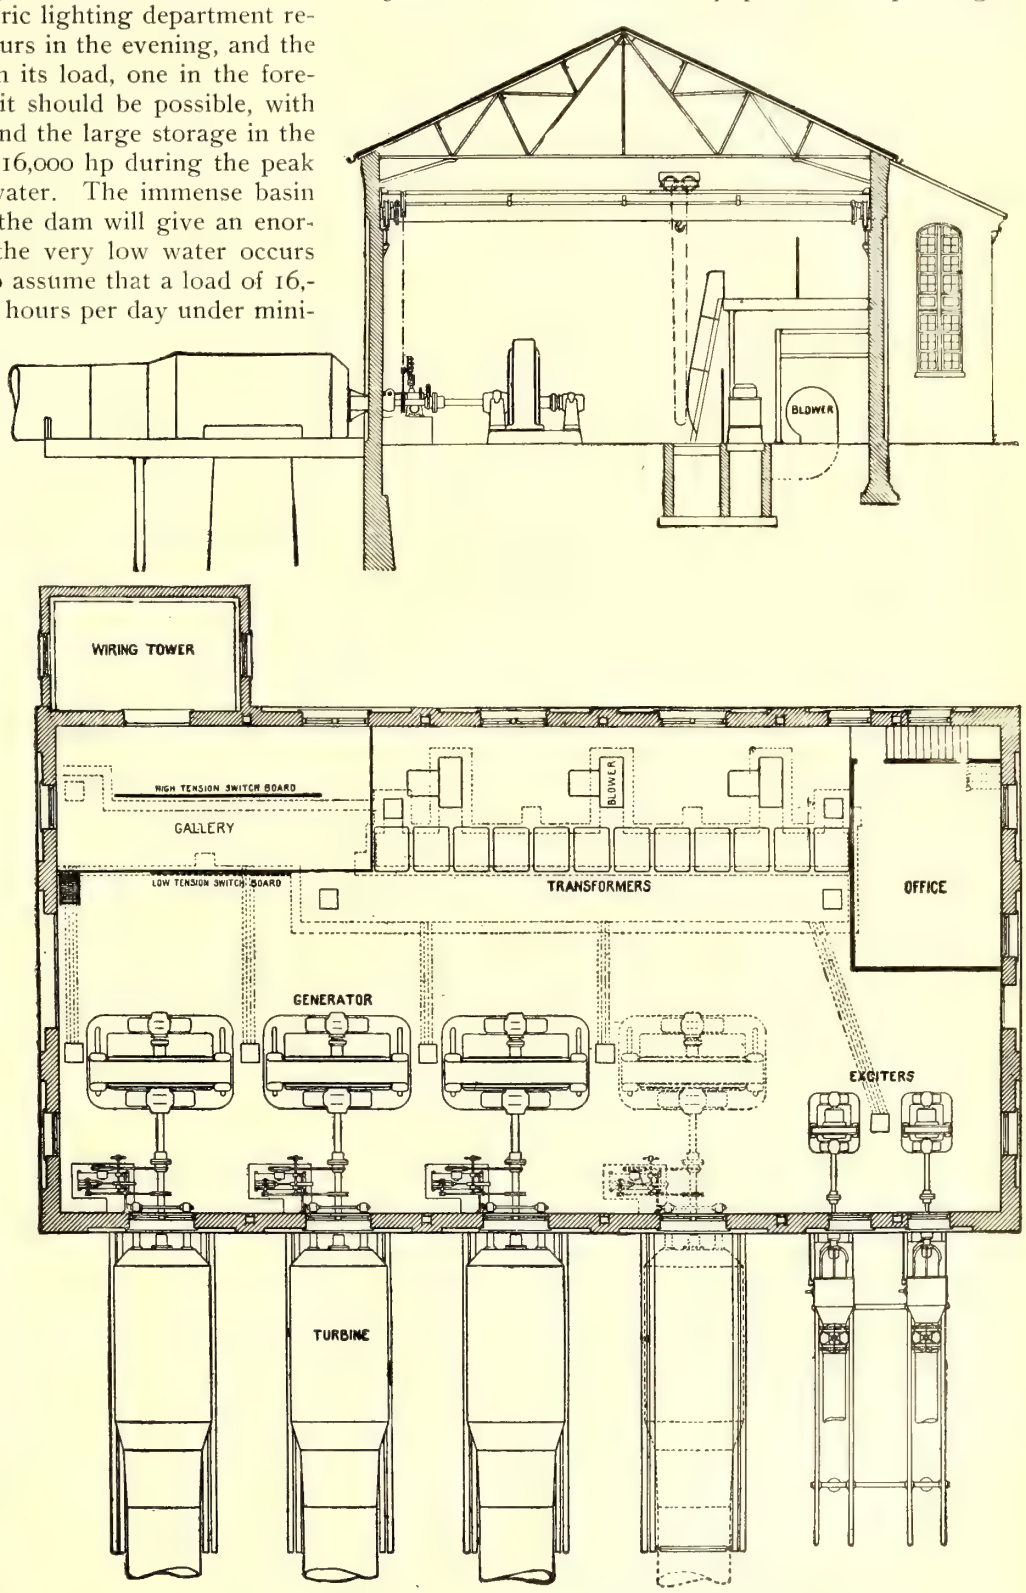


SADDLE FOR SUPPORTING MAIN FEEDER TUBE

there was a minimum of at least 6500 hp flowing through the twenty-four hours of the day. This was based upon accurate measurements, and on an assumption of a much lower water level than was actually found at any time during the summer or as stated by the old residents of Parnahyba. Inasmuch as the electric lighting department requires the power only a few hours in the evening, and the street railway has two peaks in its load, one in the forenoon and one in the evening, it should be possible, with this amount of water flowing and the large storage in the dam, to operate the station at 16,000 hp during the peak of load at the season of low water. The immense basin formed by the construction of the dam will give an enormous storage capacity. As the very low water occurs for a few days only, it is safe to assume that a load of 16,000 hp could be carried for ten hours per day under minimum conditions. With the exception of these few days there will always be at least double this amount, and during the high water season there is at least 140,000 hp available. The rise of water is very gradual, and there are never any sudden freshets in the river; there is also an absence of ice, consequently the troubles and dangers due to cold weather, connected with the operation of the hydraulic plants in the north, are absent. The work on the hydraulic power station is progressing rapidly, and it is hoped that the first power can be obtained from there about the first of next year.

The transmission line from Parnahyba to Sao Paulo will consist of two independent three-phase circuits, designed to operate at 25,000 volts. These circuits consist of No. 0 bare copper wire, and each is of sufficient size to transmit 2200 kw with a loss of about 10 per cent. Octagonal wooden poles are used, 34 ft. long, on which are supported two cross-arms, the braces and other pole fittings being of galvanized iron.

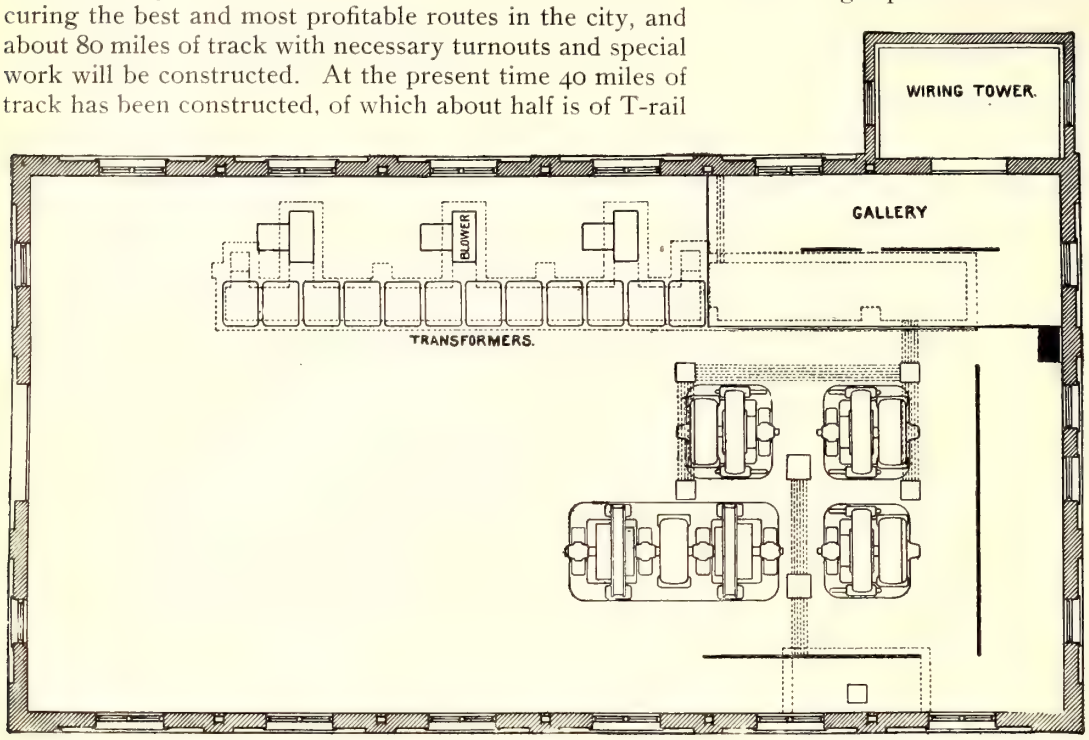
All of the current required for lighting power and street railway purposes will be distributed from a central step-down sub-station, in which the high-tension current at 23,000 volts will be reduced to 2300 volts, and where will also be located motor-generators, for the conversion of the alternating current to a 500-volt direct current for street railway use. This station will consist of a fireproof building, equipped with traveling crane. The electrical installation will consist of three 500-kw induction motors, direct-connected to 575-volt direct-current railway generators, and a synchronous motor set will probably be added. The motor-generators have been used instead of rotary converters, as it is claimed that they will give better regulation on the periodicity adopted, 60 cycles per second. There is also 600 arc lamp capacity of constant current transformers, ten 400-kw potential regulators for lighting circuits, twelve step-down transformers of total maximum capacity of 5600 kw, and switchboard equipments for operating the high and low-tension circuits, and for connecting the electrical apparatus above enumerated. These boards are very complete, and are equipped with the latest type of apparatus, consisting of two high-tension line panels, ground detector panel, four high-tension transformer panels, four low-tension transformer panels, one totalizing lighting panel, four motor panels, four railway generator panels, ten power-circuit panels, arc light circuit



ELEVATION AND PLAN OF POWER HOUSE—PARNAHYBA

panels for twelve 50-light circuits, and ten railway feeder panels.

The railway lines have been laid out with the view of securing the best and most profitable routes in the city, and about 80 miles of track with necessary turnouts and special work will be constructed. At the present time 40 miles of track has been constructed, of which about half is of T-rail and half of girder rail, Pennsylvania Steel Company's sections, No. 242 and No. 243 respectively.



PLAN OF SUB-STATION—SAO PAULO

The girder rail used is 7 ins. high, weighing 90 lbs. per yard, having a lip inside of the groove, which is on the level with the tread of the rail, for the purpose of preserving the pavement. The rails have a 6-in. base, resting on concrete stringers, with steel ties placed 10 ft. apart. These steel ties are made of 7-in. channels, and are 5 ft. 9 ins. long, imbedded in concrete. Drop forged brackets are used, four to each tie, for the purpose of bracing the rail.

STREET SCENE IN SAO PAULO—LAYING TRACK

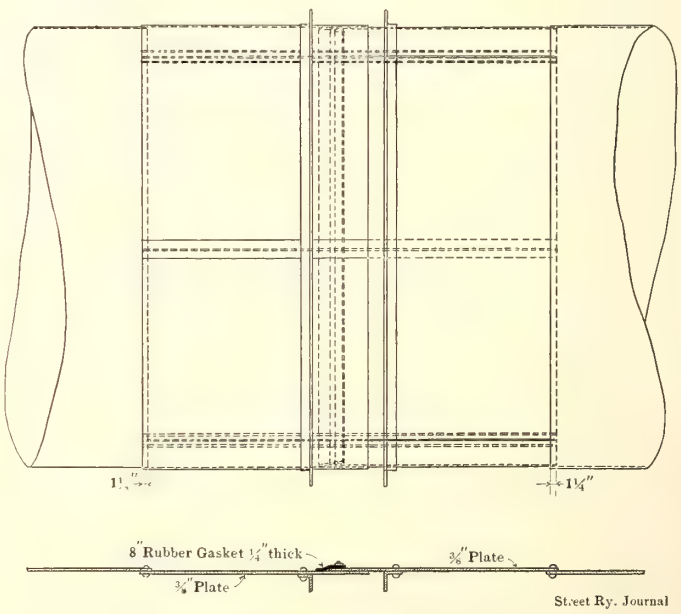
The whole surface is covered over to a distance of 2 ft. outside of each rail with a 4-in. layer of concrete, and to 5 ins. below the tread of the rail to allow for paving blocks. The T rails are 6 ins. high, weighing 62 lbs. per yard. The rails are placed on wooden ties, spaced 2 ft. apart, with four brackets to each tie, through which the rails are spiked to the ties, the whole lying on a layer of concrete 4 ins. thick.

On part of the line steel ties are used in place of the wooden ties. Both the T rail and girder rails are bonded with the West End type of bond.

The single pole overhead construction is illustrated in the engraving. This form is used in many places, but in the center of the city span wires are stretched from poles at the curbs.

The company is operating at the present time fifteen nine-bench open cars of the J. G. Brill Company's make. The cars are 29 ft. 8⅜ ins. in length over the crown pieces, and have a seating capacity of forty-five. They are mounted on Brill 21-E trucks, having a wheel base of 8 ft., and wheels 30 ins. in diameter. The cars are finished in cherry and ash, with a ceiling of three-ply birch veneer, neatly decorated. The cars are equipped with the Neal electric headlights and the Millen illuminated signs. Orders have just been placed with the St. Louis Car Company for fifty additional cars, to be of the same general design and finish as those now in use, and fitted with the same style trucks.

The motor equipments consist of General Electric Type 58 motors. These are rated at 37 hp each, and there are two motors per car.



DETAILS OF EXPANSION JOINT IN MAIN FEEDER TUBE

The electric light system will consist of an underground installation for the center of the city, of a capacity sufficient to supply 10,000 16-cp incandescent lamps and 200 arc lamps. The remainder of the city and the suburbs will be supplied by an overhead system completely covering the entire territory, so that the current can be supplied in any street of the city or suburbs where there is a demand.

On account of the extremely high price of gas, due to the excessive cost of coal, and the great cost of kerosene

oil and other illuminants, the use of electric light will be almost universal, as already indicated by applications to the company, and the electric light system will need to be as extensive and general as the distributing system of a

T RAIL AND CENTER POLE CONSTRUCTION

gas company ordinarily is in a large city. The total capacity of the electric light system in wiring and transformers will be sufficient to supply 50,000 16-cp lamps and 800 arc lamps.

The system of distribution adopted is a single-phase alternating circuit, 2300-volt, 2-wire primary, with a network system of 3-wire secondary mains, at 115 volts. By means of a proper arrangement of feeders and location of transformers, a uniform potential will be maintained in the secondary network. It is proposed to operate from this system all the small motors and fans, for which there is a large demand, as well as to supply current for heating and cooking purposes.

In addition there will be installed a complete system of circuits for power distribution, reaching all sections of the city where power is used. In the central section of the city the motors will be supplied from a three-phase 430-volt underground circuit, the circuit being supplied from transformers situated in the lighting transformer vaults. The remainder of the city will be supplied by a three-phase 2300-volt overhead circuit.

It was very important to commence the operation of the company's lines in Sao Paulo at as early a date as possible, and as the hydraulic plant could not be built within eighteen months, it was deemed best to order a small temporary steam plant for the operation of the first electric lines. This plant, which is now in operation, consists of two 350-hp engines, built by the Robb Engineering Company, of Amherst, N. S., directly connected to 225-kw generators. This plant will operate about twenty cars. As already mentioned, fifteen cars only are now in operation, for which a small car house has been erected.

When the power is supplied by the hydraulic power station at Parnahyba, the cost of operating the tramway lines will be low, as open cars only are required, and there will be no snow expenses, while the wages of all classes of labor are very much lower than the ruling wages in this country. The cost of operating the plant at Parnahyba and the distribution of the current in Sao Paulo for lighting and for manufacturing purposes will also be very low. The men required for the direct operation of the plant will be experienced and well paid, but few of this class are needed, and the great body of employees required for the maintenance of the transmission lines in the city and the general conduct of the business will be of the ordinary laboring classes, so that the cost of producing and distributing the power will be fully as low, and probably less, than with any hydraulic power station in this country. Under these conditions it is believed that the ratio of net to gross income will be very high.

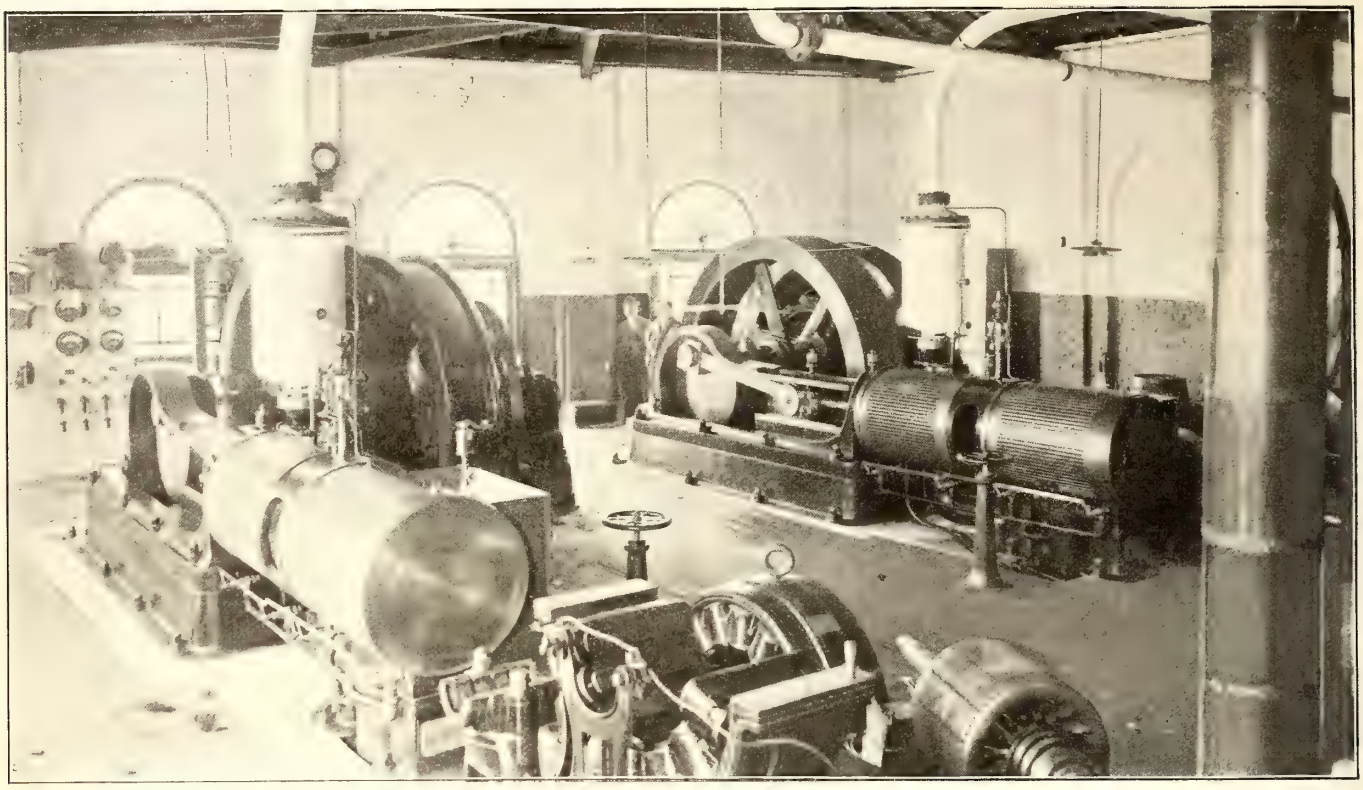
The contracts for the track materials, electrical and hydraulic equipment were placed a year ago at prices much less than those prevailing at the present time, and the cost of construction is being carried out well within the amounts estimated by the company's engineers.

At the time of the organization of the Sao Paulo Company and the commencement of the work there were two rival companies engaged in business in the city, one the Viacao Paulista, with about 57 miles of track, doing a street railway business with animal traction, the other the Agua Luz, operating an electric light business and supplying about 5000 incandescent lamps and 100 arc lamps. Negotiations are under way for the absorption of these two companies by the Sao Paulo Tramway, Light & Power Company, Ltd. The Viacao Paulista owns and operates two independent railway systems, one situated in the city

STREET SCENE IN SAO PAULO, SHOWING ONE OF THE OLD CARS

of Sao Paulo and the other in Santos, a city of 60,000 inhabitants, about 50 miles distant from Sao Paulo, and one of the most important ports in Brazil. The plant and equipment of the Viacao Paulista includes about 57 miles

of track in Sao Paulo, 153 passenger cars, with an average seating capacity of twenty-three, twenty-six freight cars,



INTERIOR OF STEAM POWER STATION, SAO PAULO

two locomotives, 2300 mules, and ten car shops and stables.

The company has in its employ in charge of the work at Parnahyba H. L. Cooper, one of the best known hydraulic engineers in this country. The general business of the company in Brazil is under the charge of Robert C. Brown, formerly electrical engineer of the West End Street Railway, of Boston, afterwards chief engineer of the Montreal Street Railway Company, and later general manager of the Halifax Electric Tramway Company, of Halifax, N. S. A. Mackenzie, of the firm of Blake, Lash & Cassels, of Toronto, is in charge of the legal interests of the company.

Changing the Broadway Road From Cable to Electric Power

The Metropolitan Street Railway Company, of New York, is utilizing the usually slack traffic months of July and August to make the necessary changes in the conduit of the Broadway cable railway to fit it for electric traction. This work is in line with the policy of the company, announced some time ago by President Vreeland, to change over all of its cable lines to the underground trolley system. The work is being carried on in sections of three or four blocks in length, so as not to obstruct the street to any greater extent than is necessary, and a section is completed and paved in before the adjoining section is opened. The reconstruction is being carried on without interfering with the operation of the cable cars, and as these cars run under a thirty-second headway during the greater portion of the day, and as the reconstruction not only involves radical changes in the conduit itself, but renewal of all tie-rods and track rails, it will readily be seen that the task is one of no small engineering difficulty. It is done by keeping the men at work as long as possible between bunches of three or four cars, then having them

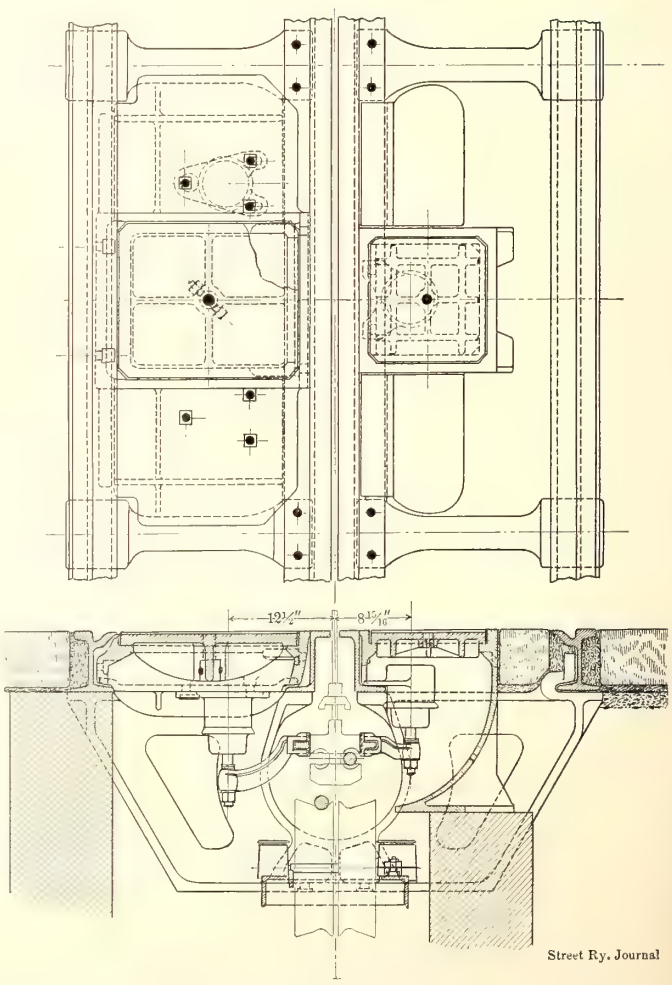


FIG 1.—SECTION AND PLAN, SHOWING BROADWAY CONDUIT, ELECTRICALLY EQUIPPED

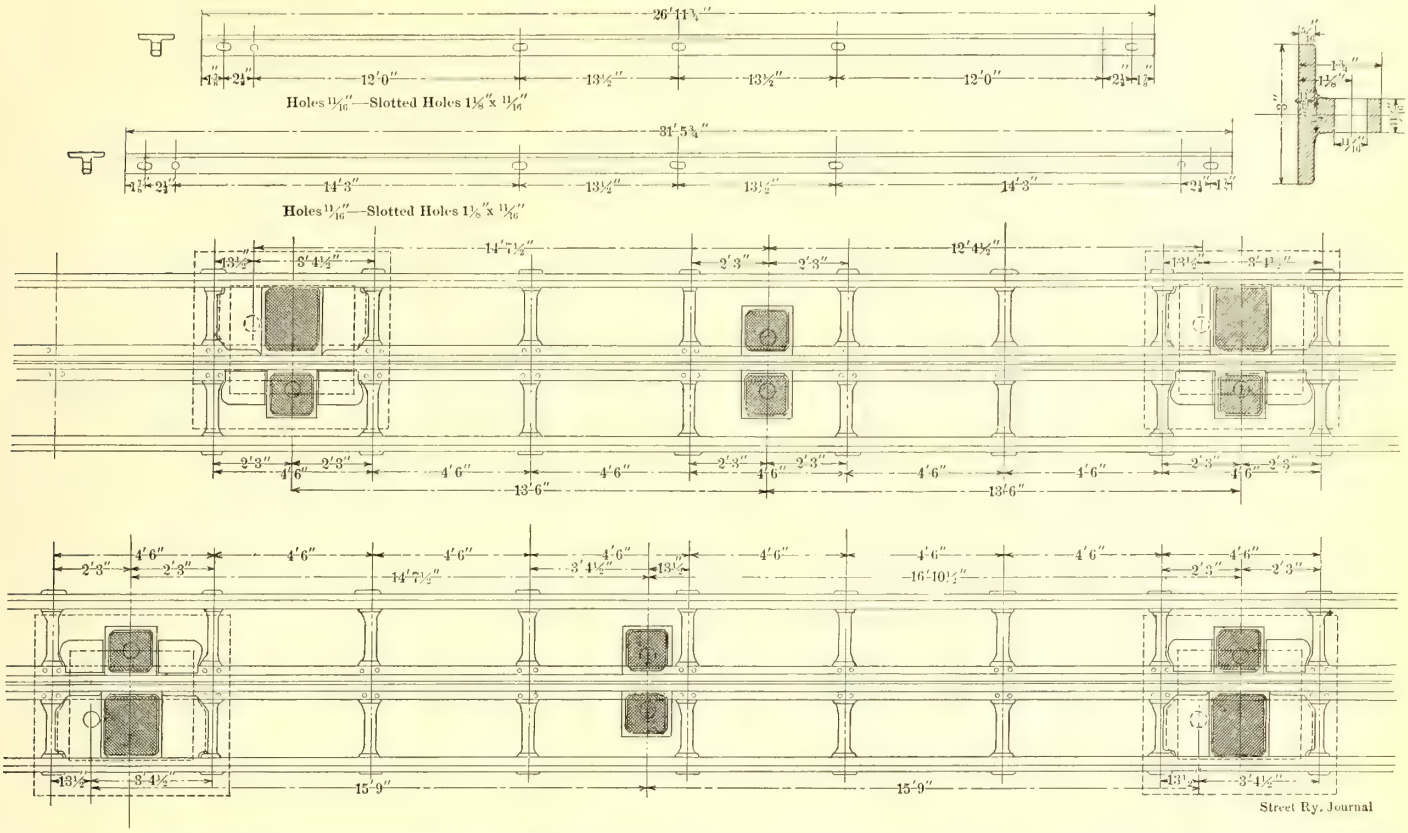
suspend operations until these cars have passed, then beginning their work again quickly. Of course at night the headway is much longer, and this allows the men to work under much more advantageous conditions.

The accompanying diagram, Fig. 1, shows a cross sec-

tion and plan of the Broadway conduit, as adapted for electric traction. For convenience of reference the existing cable sheaves and grip are superimposed on the section in light lines in their correct position. In the present work the insulators, brackets and conductors are not being installed, this being left for a later date, when they can be



GENERAL PLAN OF BROADWAY CONDUIT, SHOWING THE TWO STANDARD SPACINGS OF HAND-HOLES, ALSO CONDUCTOR BARS

put in place through the hand-holes and grip hatches without disturbing the pavement.

The principal work now being done on the conduit itself is the cutting of the concrete for, and the setting in place of, the hand-hole curbs. In the original Broadway conduit the yokes were 4 ft. 6 ins. apart, and the carrier pulley vaults were spaced either 27 ft. or 31 ft. 6 ins. apart, depending upon local conditions. As shown in the plan, Fig. 1, which is of the conduit at such a vault, the old manhole cover was on one side of the slot rails only. This cover will not be interfered with, but the insulator for that side of the conduit will be supported on either one side or the other of the cover, depending on the spacing. Directly opposite each of these covers, however, a special hand-hole curb is being installed, as shown. This curb is of cast iron, rests on a concrete base, and is grouted in place. Midway between each manhole, also, similar hand-holes are being installed for insulators, so that the latter will be located either 13 ft. 6 ins. or 15 ft. 9 ins. apart. The original conduit was lined with sheet iron. This necessarily had to be cut away at the hand-holes, but is being left in position between the hand-holes. The form of conductor bars and insulators to be used is the same as on the rest of the system, and is shown in both engravings.

The method to be followed when the insulators and conductors are introduced in the conduit has not yet been announced, and this forms a very interesting problem. As will be seen from the section, if these conductors are placed in position while the cable is in use, the grip will be apt to collide with the conductors, and break the insulators. On the other hand, if cable operation is stopped during the considerably long process of introducing the insulators and conductors, the financial loss, owing to a suspension of traffic, would be considerable. It will be remembered that in the conversion of the Third Avenue Railroad the insulators were mounted on rods, so that they could be slid to the side of the conduit and equipped. When the company was ready to make the change to electricity, the cable was stopped and all the insulators in a section were slid forward into position together, taking a much shorter time than if all the work of placing them in position had to be done when cable operation was suspended. On the other hand the Capital Traction Company, of Washington, D. C., in altering over its Pennsylvania Avenue cable line to electricity, ran horse cars during the interruption.

Street Car Building

(Stephenson Practice)

BY CHARLES HENRY DAVIS, C. E.

VIII.—Assembling—(Continued)

In the August issue of the STREET RAILWAY JOURNAL we gave the details of the roofs for our two standard cars, namely, the Boston (closed) and the Brooklyn (open). Tables Nos. 37 and 38 give respectively the details of platforms for the standard cars, while Plates IX. and X. illustrate the various parts. As in tables Nos. 31, 32, 33, 34, 35 and 36, each distinct part of the platforms is described, giving the material, the general dimensions, how made, on what tools and how assembled, all in consecutive order as each car is built in the shop. In using these tables they are to be read across the page, line by line, as in the case of any book. In column 1 the numerals indicate, in consecutive order, the number of distinctive pieces; where a letter follows the numeral it indicates another operation, but not another distinctive piece. Letters in column 4 are the same abbreviations of woodwork and metal work as used on Plates I. and II. These tables are given on the following pages.

Table No. 37

Detail of Platforms of Boston Closed Car, in the Order of Assembling

(25 ft. Body; Car No. 2; Fig. 3; Plates I. and IX.)

Consecutive Number	Quantity	Name of Piece	Piece Number Plates I. and IX.	Material See Plates I. and II.	Details: Quantity	Details: Name	Details: Reference Letter Plate IX.	Dimensions	Observations and Particulars of How Used	Tools Usually Employed (Others can be used if convenience or necessity requires)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
									The various pieces of which the platforms are composed are assembled independently of all others, as was seen to be the case with the roofs, etc., and when completed they are attached to the car. These pieces are —	
166	2	**Crown-pieces** (Fig. 296)	3003	O.	--	----------	--	6 ft. 1¾ in. x 14½ in. x 2¾ in.	Each having :—	
					2	Holes	a	9-16 in. diam.	For platform outer-sill (3001) bolts	Borer
					4	Holes	b	9-16 in. diam.	For platform inner-sill (3002) bolts	Borer
					2	Holes	c	13-16 in. diam.	For dasher short-end-posts (3504)	Borer
					2	Holes	d	13-16 in. diam.	For dasher center-posts (3505)	Borer
					2	Holes	e	13-16 in. diam.	For dasher intermediate-posts (3506) through platform outer-sills	Borer
					1	Hole	f	9-16 in. diam.	For pedal alarm-gong pin (3564)	Borer
					1	Hole	g	7-16 in. diam.	For brake-shaft pawl-pin (3527)	Borer
					1	Hole	h	4 in. x 1⅝ in.	For wiring	Borer
					2	Holes	i	9-16 in. diam.	For bolts for brake-shaft lower-bearing (3517) Fig. 331	Borer
					2	Holes	k	9-16 in. diam.	For bolts for platform step-hanger (3531)	Borer
167	4	**Platform outer-sills** (Fig. 294)	3001	A.	--	----------	--	6 ft. 8 in. x 7½ in. x 3 in.	Each having :—	
					1	Gain	a	10¾ in. x 2¾ in.	For crown-piece to rest on	Band saw or shaper
					2	Chamfers	b	----------	To round off the sharp edges	Chamfering machine
					1	Hole	c	9-16 in. diam.	For 7 in. x ½ in. round-head bolts to secure the crown-piece through holes (a) of the crown-piece	Borer
					1	Hole	d	13-16 in. diam.	For securing crown-piece by means of intermediate-post through hole (e of crown-piece	Borer
					1	Tie-bolt	e	6 in. x ½ in.	To prevent the sill from splitting at (f)	
					2	Holes	g	11-16 in. diam.	On the underside for bolts to secure the sills to the side-sills through holes (m) Fig. 33, Plate IV.	Borer
168	4	**Platform inner-sills** (Fig. 295)	3002	A.	--	----------	--	5 ft. 11 in. x 7 in. x 2¾ in.	Each having :—	
					1	Gain	a	14 in. x 2½ in.	For crown-piece to rest on	Band saw or shaper
					1	Gain	b	4½ in. x ½ in.	For iron buffer. These are on the underside of this part, but not seen	Band saw or shaper
					2	Holes	--	9-16 in. diam.	For 7 in. and 6⅛ in. x ½ in. round-head bolts to secure crown-piece through holes (b) of the crown-piece	Borer
					1	Tie-bolt	c	6 in. x ½ in.	To prevent the sills from splitting at (d)	
					1	Hole	e	13-16 in. diam.	On underside, for bolts to secure the sills to the intermediate cross-sill (6) Fig. 38, Plate IV. (*see Con. No. 6, Table No. 31*), through hole (h)	Borer
					1	Hole	f	13-16 in. diam.	On underside, for bolts to secure the sills to the end-sills (2) through hole (e) Fig. 36, Plate IV. (*See Con. No. 10, Table No. 31.*)	Borer
					2	Chamfers	g	----------	To round off the sharp edges	Chamfering machine
169	8	**Platform flooring-boards** (Figs. 297, 298)	3004	Y. P.	--	----------	--	4 in. wide, 1 in. thick	Having :—	
					2	Gains	a	----------	Next the car body to allow rain water on the platform to fall through to the ground. They are screwed to the sills with 128 No. 12 in. x 1¾ in. steel screws	Shaper
170	4	**Crown-piece corner-irons** (Fig. 307)	3501	W. I.	--	----------	--	17 in. x 2¾ in. x ⅛ in.	Each having :—	
					1	Hole	a	----------	For No. 12 in. x 1½ in. steel screws to secure it to the crown-piece	Power punch
					1	Hole	b	----------	For 2½ in. x ½ in. lag screws to secure it to the crown-piece	Power punch
					4	Holes	k	----------	For bolts, same as shown at (k) Fig. 296, for platform step-hangers	Power punch
171	4	**Dasher short-end-posts** (Fig. 312)	3504	W. I.	-	----------	--	2 ft. 1 1-16 in. x 1½ in. x ⅞ in.	Are now inserted in holes (c) Fig. 296, of the crown-piece, the	
172	4	**Dasher-post washers** (Fig. 317)	3507	C. I.	--	----------	--	3½ in. x 1¼ in.	Being first slipped over the end of the post; they are then tightened up with the flat washer and nut under the crown-piece	
173	4	**Dasher center-posts** (Fig. 313)	3505	W. I.	--	----------	--	2 ft. 8¼ in. x 1½ in. x ⅞ in.	Inserted in holes (d) of the crown-piece, and with	
173a	4	**Dasher-post washers** (Fig. 317)	3507	C. I.	--	----------	--	3½ in. x 1¼ in.	Are tightened up with the flat washer and nut under the crown-piece	
174	4	**Dasher intermediate-posts** (Fig. 314)	3506	W. I.	--	----------	--	2 ft. 8¼ in. x 1½ in. x ⅞ in.	Inserted in holes (e) of the crown-piece, and through holes (d) of the platform outer-sills, and with	
174a	4	**Dasher-post washers** (Fig. 317)	3507	C. I.	--	----------	--	3½ in. x 1¼ in.	Are tightened up with the flat washer and nut under the crown-piece	
175	2	**Dashers** (Fig. 299)	3511	S. S.	--	----------	--	2 ft. 8 in. x 5 ft. 10 in.	No. 14 gage, bent to fit around the crown-piece, to which they are secured with 20 No. 12 x 1 in. blued steel screws through holes (a), they are fastened to the dasher short-end-posts with	
176	12	**Dasher end-posts straps** (Fig. 311)	3508	W. I.	--	----------	--	1 in. wide	Slid over the end-posts and bolted to the dashers through holes (b) with 24 round-head ¼-in. stove bolts	
177	8	**Dasher-post top-clips** (Fig. 315)	3509	W. I.	--	----------	--	1 in. wide	Bolted round the center and intermediate-posts to the dashers through holes (c) with 16 round-head ¼-in. stove bolts	
178	8	**Dasher-post bottom-clips** (Fig. 316)	3510	W. I.	--	----------	--	1 in. wide	Bolted round the center and intermediate-posts to the dashers through holes (d) with 16 round-head ¼-in. stove bolts	
179	2	**Iron-buffers** (Fig. 334)	3530	M. I.	--	----------	--	22 in. x 5 in.	Are now bolted to the crown-piece with two bolts, 4¼ in. x ½ in., and to the crown-piece through the platform inner-sills with 4 bolts, 5¾ in. x ½ in., countersunk round heads, and screwed to the crown-piece through holes (a) with 4 lag screws, 3½ in. x ½ in. The undersides of the platforms now receive 2 coats of lead paint mixed in oil, after which they are attached to the car body, the platform outer-sills being secured with 4 bolts 12½ in. x ⅝ in. and 4 bolts 15¼ in. x ⅝ in. through holes (g) of the outer-sills and the holes (m) of the side-sills, Fig. 33, Plate IV. Further, 4 bolts 16½ in. x ¾ in. and 4 bolts 20 in. x ¾ in. are passed through the holes in	
180	4	**Platform-sill clamps** (Fig. 304)	3502	W. I.	--	----------	--	----------	Which are placed under the part (h) of the outer-sills, then the 16½ in. bolts are passed through holes (d) in the end-sills, and the 20 in. bolts through holes (l) in the side-sills, Fig. 33, Plate IV., and holes (b) in the end-sills, Fig. 36, Plate IV., and are well screwed up	
181	4	**Sill-bolt beveled-washers** (Fig. 305)	3503	C. I.	--	----------	--	----------	Are inserted under the bolt nuts on the sloping underside of the outer-sills to give a firm bearing. The platform inner-sills are then secured with 4 bolts, 9 in. x ¾ in. through holes (e) of the inner-sills and the holes (h) of the intermediate cross-sills, Fig. 38, Plate IV., and 4 bolts, 16½ in. x ¾ in. through holes (f) of the inner-sills, and the holes (e) of the end-sills, Fig. 36, Plate IV., there being used	
181a	4	**Sill-bolt beveled-washers** (Fig. 306)	3503	C. I.	--	----------	--	----------	For the holes (e) of the inner-sills	
									The following are now adjusted and secured, to a large extent in the order given, though for convenience or other reasons this may be sometimes departed from.	

182	8	**Platform step-hangers** (Fig. 308)	3531	S. S.	--		--	3-16 in. thick	In pairs, are now bolted to the platform step-hanger brackets (1512), Fig. 123, Plate V. (*see Con. No. 85, Table No. 33*, with 8 bolts, 1½ in. x ⅜ in., clearly shown in Fig. 351, and to the crown-piece through holes (k), Fig. 296, with 4 6 in. and 4 7 in. x ½ in. bolts. They are further secured with	
183	4	**Platform-step hook-bolts** (Fig. 320)	3531	W. I.	--		--	4 in. x ⅜ in.	Bolted through the platform outer-sills, and hooked to the step-hanger as shown in Fig. 359	
184	4	**Platform-step tread-boards** (Fig. 310)	3005	A.	--		--	2 ft. 8 in. x 12 in. x 1 in.	Bolted to platform step-hangers with 32 countersunk bolts 1½ in. x 5-16 in. through holes (a)	
185	4	**Platform step-fenders** (Fig. 309)	3534	M. I.	--		--	2 ft. 9 in. x 7⅛ in. x 4¾ in. x ¼"	Screwed to the front of the tread-boards and outer-sills with 40 No. 12 x 1 in. steel screws	
186	4	**Platform-step tread-board facing-irons** (Not Ill.)	3533	W. I.	--		--	⅞ in. half-round	Screwed to the front of the tread-boards with 36 No. 14 x 1 in. steel screws	
187	2	**Switch-stick rings** (Fig. 318)	3560	M. I.	--		--		Placed on the left-hand dasher intermediate-posts, resting on the dashers	
188	2	**Trolley-cord rings and snaps** (Fig. 319)	3561-2	M. I.	--		--		Placed on the left-hand dasher center-posts, resting on the dashers	
189	2	**Dasher-rails** (Fig. 302)	3512	W. S.	--		--	5 ft. 5½ in. x 1¼ in. x ⅜ in.	Is adjusted to the dasher-posts by the 4 holes (a) and secured by the nuts shown; there are further in each rail:—	
					5	Holes	b	5-16 in. diam.	For bolts to hold the dasher rail-caps (3513), Fig. 303	Drill press
					2	Holes	c	5-16 in. diam.	For bolts to secure the dasher-rail grab-handle (3514), Fig. 300	Drill press
					2	Holes	d	⅜ in. diam.	For bolts to secure the brake-shaft upper-bearing (3516), Fig. 328	Drill press
190	2	**Dasher-rail caps** (Fig. 303)	3513	Bz.	--		--	5 ft. 7 in x 2 in. x ⅞ in.	Bolted to the dasher rails with 10 square-head bolts, 1¾ in. x ¼ in. through holes (b)	
191	4	**Dasher-rail grab-handles** (Fig. 300)	3514	Bz.	--		--		Adjusted to the dasher intermediate and short end-posts and secured to the dasher-rails with 4 round head bolts, 1 in. x ¼ in., through holes (c) and with the bolts going through holes (b) of the dasher-rail. They are secured to the short end-posts with	
192	4	**Dasher-rail grab-handle nuts** (Fig. 301)	3515	Bz.	--		--		Screwed to the short end posts	
193	--	**Brake-shafts complete** (Fig. 321)	3519	----	--		--		Consisting of:	
193a	2	**Brake-shafts** (Fig. 321)	3520	W. I.	--		--	1½ in. diam.	With	
194	2	**Brake ratchet-handles** (Figs. 321, 322)	3521	Bz.	--		--		In which are	
195	2	**Brake ratchet-handle upper-ratchets** (Fig. 323)	3522	M. I.	--		--		With	
196	2	**Brake ratchet-handle springs** (Fig. 324)	3524	W. S.	--		--		While to the top of the brake-shafts are secured	
197	2	**Brake ratchet-handle lower-ratchets** (Fig. 321)	3521	M. I.	--		--		Which interlock with the upper-ratchets	
198	2	**Brake-shaft upper-bearings** (Fig. 328)	3516	M. I.	--		--		Bolted to dasher-rail through holes (d), Fig. 302, with 4 bolts 1¾ in x 5-16 in.	
199	2	**Brake-shaft lower-bearings** (Fig. 331)	3517	M. I.	--		--		Bolted to the crown-piece through holes (i), Fig. 296, with 4 bolts 14 in. x ½ in.; the cut-outs (e), Fig. 299, at the bottom of the dasher fit round these pieces and also make room for	
200	2	**Brake-shaft ratchets** (Fig. 329)	3525	C. I.	--		--		Fitted tight to the brake-shaft and keyed	
201	2	**Brake-shaft pawls** (Fig. 326)	3526	M. I.	--		--		Are secured to the crown-piece by means of	
202	2	**Brake-shaft pawl-pins** (Fig. 325)	3527	W. I.	--		--		Which are bolted through	
203	2	**Brake-shaft pawl-washers** (Fig. 327)	3528	M. I.	--		--		The brake-shaft pawl and hole (g) in the crown-piece, Fig. 296	
204	2	**Brake-chains** (Fig. 332)	3529	W. I.	--		--	⅜ in., 30 in. long	Are bolted to the brake-shaft through the hole (a) below the ratchet, Fig. 321	
205	2	**Brake-shaft steps** (Fig. 330)	3518	C. I.	--		--		Are bolted later to the drawbar-rest (3007), Fig. 348, through the holes (c) with 4 bolts 3¼ in. x 5-16 in.	
206	--	**Drawbar spring-castings complete** (Fig. 335)	3535	----	--		--		Composed of:—	
206a	2	**Drawbar spring-castings** (Fig. 336)	3536	M. I.	--		--		Bolted under the platform to the platform inner-sills with 4 bolts 9½ in. x ⅝ in. and 8 bolts 9 in. x ⅝ in. through holes (a)	
207	2	**Drawbar springs** (Fig. 339)	3537	W. S.	--		--		Fitting inside the casting, while going through it and the ends of the casting are	
208	2	**Drawbar-heads** (Fig. 341)	3539	M. I.	--		--		Upon which at each end of the springs fit	
209	2	**Drawbar spring-plates** (Figs. 337, 338)	3538	M. I.	--		--		The heads are held in the castings by means of	
210	2	**Drawbar-head keys** (Fig. 335)	3549	W. I.	--		--		Inserted in the end of the heads, through the slot (a), Fig. 341. When the car is to draw a trailer	
211	2	**Drawbar plain radial-bars** (Fig. 349)	3544	W. I.	--		--	4 ft. 2 in x 2¼ in. x 1⅛ in.	Are inserted between the jaws (b) of the head (3589) and secured by	
212	2	**Drawbar coupling-pins** (Fig. 340)	3540	W. I.	--		--		Which are prevented from being jolted out by	
213	2	**Drawbar coupling-pin cotters** (Fig. 335)	3541	W. S.	--		--		Inserted in holes in the pins. To complete the outfit for trailers	
214	1	**Drawbar coupling-link** (Fig. 344)	3546	M. I.	--		--		Is secured by one of its	
215	2	**Drawbar coupling-link pins and chains** (Fig. 344)	3547	W. I.	--		--		To the other end of the drawbar radial-bar (3544), the other end being similarly coupled to the trailing car	
216	1	**Drawbar coupling-link box** (Fig. 343)	3008	W. P.	--		--		For stowing away the coupling-link when not in use, is secured to the underside of the car bottom by	
217	2	**Drawbar coupling-link box-straps** (Fig. 342)	3559	W. I.	--		--		Secured to the link-box with 12 No. 14 x 1 in. steel screws, and to the car bottom with 4 No. 14 x 1¼ in. steel screws	
218	--	**Drawbar supporting-frames complete** (Fig. 359)	----	----	--		--		Composed of	
218a	2	**Drawbar-rests** (Fig. 348)	3007	A.	--		--	6 ft. 0 in. x 3 in. x 1½ in.	With	
219	2	**Drawbar-rest wearing-plates** (Fig. 350)	3550	W. I.	--		--		Screwed to the rests with 20 No. 14 x 1 in. steel screws. To these rests are secured one end of each of the following supporting pieces, the other ends of same being secured to the platform:—	
220	4	**Drawbar-rest hangers** (Fig. 352)	3552	W. I.	--		--	1 ft. 5 in. x 1½ in. x ½ in.	Bolted to the drawbar-rests through holes (b) with 4 bolts, 3¼ in. x ½ in. and to the crown-pieces with 4 bolts 3¾ in. x ½ in. countersunk heads	
221	4	**Drawbar-rest hangers** (Fig. 353)	3552	W. I.	--		--	1 ft. 5½ in. x 1½ in. x ½ in.	Bolted to the drawbar-rests through holes (a) with 4 bolts 3¼ in. x ½ in., and to the crown-pieces with the dasher short-end-posts (3504)	
222	4	**Drawbar-rest braces** (Fig. 358)	3553	W. I.	--		--	1½ in. x ¼ in.	Bolted to the drawbar-rests through holes (b) with the same bolts as used for the hangers, Fig. 352, and to the platform outer-sills with 4 bolts 3¾ in. x ½ in.	
223	20	**Drawbar-rest toe-guards** (Fig. 354)	3554	W. I.	--		--	½ in. diam.	Screwed to the drawbar-rests with 20 No. 12 x 1 in. steel-screws, and to the crown-pieces with 20 No. 12 x 1 in. steel screws	
224	2	**Drawbar-guards** (Fig. 347)	3006	A.	--		--	4 ft. 4 in. x 3 in. x ¾ in.	Bolted to the drawbar-rest hangers, Fig. 352, through holes (a) with 4 bolts, 1½ in. x ⅜ in.	
225	4	**Fender-slides** (Fig. 357)	3555	M. I.	--		--		In pairs, bolted through holes (a) to the drawbar-rest through holes (a) with the same bolts as used for the hangers, Fig. 353, and through holes (b) to the drawbar-rests through holes (e) with 8 bolts, 3¾ in. x 5-16 in.	
226	4	**Fender adjusting brackets** (Fig. 355)	3556	M. I.	--		--		Bolted to the platform-step tread-boards, Fig. 310, through holes (b) with 8 bolts 2 in. x ½ in.	
227	2	**Fender holding-sockets** (Fig. 356)	3557	M. I.	--		--		With	
228	2	**Fender holding-pins** (Fig. 356)	3558	W. I.	--		--		Bolted to the drawbar rests through holes (d) with 4 bolts 2¾ in. x ½ in.	
229	2	**Upper-deck grab-handles** (Fig. 342a)	2504	W. I.	--		--		Seen in Fig. 359, screwed to the upper-deck roof with 4 No. 14 x 1½ in. and 4 No. 12 x 1½ in. steel screws	
230	2	**Pedal alarm-gongs** (Fig. 345)	3563	S.	--		--		With	
231	2	**Pedal alarm-gong castings and hammer** (Fig. 345)	3565	M. I.	--		--		Are secured to the underside of the platform with 2 bolts 5½ in. x ¾ in. and 2 bolts 3⅜ in. x ⅜ in	
232	1	**Pedal alarm-gong pin** (Fig. 346)	3564	W. I.	--		--		Passes through hole (f) in the crown-piece, and is detachable for use on either platform	
233	4	**Platform-gates and fixtures** (Fig. 333)	3566	W. I.	--		--	Wood's make	Screwed to the ends of the car with 12 No. 15 x 1¼ in., 24 No. 16 x 2 in., 8 No. 20 x 2 in. and 8 No. 20 x 1¼ in. steel screws	

Number of Distinctive Pieces	67	(Column 1)
Total Number of Pieces	235	(" 2)
Number of Bolts	244	(" 6 and 10)

106	4	**Dasher center-posts** (Fig. 363)	8504	W. I.	..	.....	..	41 in. x 1 in.	Are inserted in holes (c) of the crown-piece (5028) Fig. 62, Plate IV., passing through holes (c) of the platform inner-sills (8018) Fig. 61, and bolted underneath	
107	4	**Dasher intermediate-posts** (Fig. 362)	8505	W. I.	..	.....	..	36½ in. x 1 in.	Are inserted in holes (d) of the crown-piece (5028) and bolted underneath	
108	8	**Dasher-post washers** (Figs. 362, 363)	8506	C. I.	..	.....	..	.....	Are passed over the bottom ends of the posts before being inserted in the crown-piece holes	
109	2	**Dashers** (Fig. 360)	8501	S. I.	..	.....	..	No. 16, 6 ft. 6 in. x 2 ft. 8 in.	With hole 9⅝ in. diameter in center for electric headlights, screwed to crown-pieces through holes (■) with 48 No. 12 x 1 in. blued steel screws, round heads	
110	8	**Dasher-post bottom-clips** (Not Ill.)	8509	S. I.	..	.....	..	1⅛ in. wide, ⅛ in. thick	Bolted round the center and intermediate-posts to the dashers through holes (b) with 16 round-head ½ in. x 3-16 in. stove-bolts	
111	2	**Dasher-moldings** (Fig. 383)	8003	A.	..	.....	..	6 ft. 6 in. x 1¼ in. x ⅞ in.	Screwed to dasher through holes (c) with 46 No. 9 x ¾ steel screws	
112	8	**Dasher-post top-clips** (Not Ill.)	8508	S. I.	..	.....	..	1⅛ in. wide, ⅛ in. thick	Bolted round the center and intermediate-posts to the dashers through holes (d) with 16 round-head 1¼ in. x 3-16 in. stove-bolts	
113	4	**Dasher end-moldings** (Not Ill.)	8523	W. I.	..	.....	..	2 ft. 5¾ in. x ¾ in. x ¼ in.	Half-oval, riveted to the end of the dashers through holes (e) with 40 round-head rivets, 7-16 in. x ½ in.; the clips 8508 and 8509 are shown by Figs. 315, 316, Plate IX.	
114	2	**Dasher-rails** (Fig. 382)	8510	W. I.	..	.....	..	1¼ in. x ⅜ in.	Are adjusted to the dasher center and intermediate-posts by the holes (a) and secured by the top nuts shown in Figs. 362, 363. There are further in each rail:—	
					6	Holes	b	.....	For screws to secure the dasher-rail caps (8004) Fig. 384	Drill press
					2	Holes	c	5-16 diam.	For bolts to secure the dasher-post pipe-commode-handle (8514) Fig. 364 to the dasher-rail	Drill press
					1	Hole	d	7-16 diam.	For bolt to secure the brake-shaft upper-bearing (8528) Fig. 371 to the dasher-rail	Power punch
					1	Hole	e	7-16 diam.	For bolt to secure the switch-stick top-holder (8518) Fig. 385 to the dasher-rail	Power punch
					1	Hole	f	⅜ in.	For bolt to secure the fender hold-up eye (8522) Fig. 382, to the dasher rail	Power punch
115	2	**Switch-stick top-holders** (Fig. 385)	8518	M. I.	..	.....	..	.....	Bolted to the dasher-rail through holes (e) with 2 bolts, 1⅜ in. x ⅜ in.	
116	2	**Switch-stick bottom-holders** (Fig. 386)	8519	M. I.	..	.....	..	.....	Bolted to the crown-piece with 4 bolts 3½ in. x ⅜ in.	
117	2	**Fender hold-up eyes** (Fig. 382)	8522	M. I.	..	.....	..	⅜ in. diam.	Bolted to the dasher-rail through holes (f) with 2 stove-bolts, 1⅛ in. x 5-16 in.	
118	4	**Platform-hood supports** (Fig. 361)	8503	W. I.	..	.....	..	1¼ in. diam.	Inserted in holes (e) of the crown-piece (5028) Fig. 62, Plate IV., and bolted underneath	
119	4	**Dasher-post washers** (Fig. 361)	8506	C. I.	..	.....	..	.....	Are passed over the bottom ends of the hood-supports before being inserted in the holes in the crown-piece	
120	4	**Dasher-post pipe commode handles** (Fig. 364)	8514	Bz.	..	.....	..	12 in. long	Are passed over the top of the platform-hood supports, and bolted through holes (a) to the dasher-rail through hole (c) with 4 round-head bolts 1⅛ in. x ½ in.	
121	4	**Platform-hood-support brackets** (Fig. 366)	8515	Bz.	..	.....	..	.....	Are adjusted to the top of the platform-hood supports and screwed to the platform-hood bows with 16 No. 12 x 1¼ in. steel screws	
122	2	**Brake-shaft lower-bearings** (Fig. 369)	8529	M. I.	..	.....	..	.....	Fitted in hole (h) of the crown-piece	
123	..	**Brake-shafts complete** (Fig. 365)	8526	....	..	.....	..	.....	Composed of:—	
123a	2	**Brake-shafts** (Fig. 365)	8527	W. I.	..	.....	..	1 15-16 in. diam.	Are adjusted to	
124	2	**Brake-shaft upper-bearings** (Fig. 371)	8528	M. I.	..	.....	..	.....	Which are bolted to the dasher-rails through holes (d) with 2 bolts 1⅜ in. x ⅜ in. There are also	
125	2	**Brake ratchet-handles** (Figs. 367, 368)	8532	Bz.	..	.....	..	.....	Burns & Silver's pattern with ratchet, Fig. 368, pawl and spring, welded to the top of the brake-shaft	
126	2	**Brake-shaft ratchets** (Fig. 365)	8536	C. I.	..	.....	..	.....	Fitted tight to the brake-shaft and keyed	
127	2	**Brake-shaft pawls** (Fig. 372)	8537	C. I.	..	.....	..	.....	Are secured to the crown-piece by means of	
128	2	**Brake-shaft pawl-sleeves** (Fig. 374)	8540	C. I.	..	.....	..	.....	Upon the upper portion of which the pawl turns, and the lower portion of which is secured to the crown-piece by	
129	2	**Brake-shaft pawl-bolts and nuts** (Fig. 373)	8541	....	..	.....	..	.....	Bolted to the crown-piece	
130	2	**Brake-chains** (Not Ill.)	8542	W. I.	..	.....	..	.....	Are bolted to the brake-shaft below the ratchet	
131	2	**Brake-shaft stays** (Fig. 370)	8531	W. I.	..	.....	..	.....	Bolted to the platform inner-sills (8018) Fig. 61, Plate IV., with 4 bolts 8¼ in. x 7-16 in.	
132	1	**Center-brake-lever carrier** (Fig. 407)	8544	W. I.	..	.....	..	.....	Bolted to the center-brake-lever carrier-beam (5025) Fig. 63, Plate IV., with 4 bolts 8¼ in. x ½ in., round heads	
133	1	**Center-brake-lever** (Fig. 408)	8545	W. I.	..	.....	..	.....	Bolted to the carrier with	
134	1	**Center-brake-lever bolt** (Fig. 406)	8546	W. I.	..	.....	..	.....	And secured with the nut and cotter	
135	1	**Brake-chain connecting-rod** (Not Ill.)	8543	W. I.	..	.....	..	.....	Attached to center-brake-lever and brake-chain	
136	2	**Rigid drawbars** (Fig. 375)	8551	W. I.	..	.....	..	.....	With	
137	2	**Drawbar coupling-pins** (Fig. 377)	8559	W. I.	..	.....	..	.....	Which also passes through hole (c) of the buffer (8590) Fig. 390, and	
138	2	**Drawbar coupling-pin chains and eyes** (Fig. 377)	8561	W. I.	..	.....	..	.....	Bolted to crown-piece through holes (g) with 6 bolts 4¼ in. x ½ in., the eyes being secured with one of the buffer-bolts. (*See Con. No. 140, also Fig. 390*). The bolt also passes through one of the holes (a) of the buffer	
139	4	**Buffer-blocks** (Fig. 379)	8006	A.	..	.....	..	6⅝ in. x 3½ in. x 2¾ in.	And	
	4	**Buffer-blocks** (Fig. 379)	8006	A.	..	.....	.	6⅝ in. x 3¼ in. x 2¾ in.	Screwed to the projecting ends of the platform inner and outer-sills with 8 No. 20 x 4 in. steel screws	
140	2	**Angle-buffers** (Fig. 390)	8590	W. S.	..	.....	..	.....	Bolted through holes (a) to the platform inner and outer-sills through holes (d) and (c) Figs. 60, 61, Plate IV., with 8 bolts, 8 1-16 in. x 7-16 in.; the bolts also pass through the buffer-blocks, and the platform-hood supports pass through holes (b)	
141	4	**King-bolt-casting beams** (Figs. 391, 392)	8010	O.	..	.....	..	3 ft. 9¼ in. x 13¾ in. x 3¼ in.	Of which two are cut out at (d) to make room for the pedal alarm-gong, are bolted to the crown-pieces through holes (f) Fig. 62, Plate IV., with 4 bolts 8 in., 4 bolts 8¼ and 4 bolts 8½ in. x ½ in., countersunk heads	
142	2	**King-bolt bottom-castings** (Fig. 402)	8595	M. I.	..	.....	..	.....	Bolted to the king-bolt casting beams through holes (b) with 8 bolts, 10¾ in. x ½ in., and to the king-bolt-casting beams through holes (c) and the king-bolt beams through holes (f) Fig. 53, Plate IV., with 4 bolts 16¾ in. x ½ in.	
143	2	**King-bolt top-castings** (Fig. 404)	8594	M. I.	..	.....	..	.....	Bolted to the king-bolt beams through holes (d) with 4 bolts 5¼ in. x ⅝ in.	
144	2	**King-bolts** (Fig. 404)	8593	W. S.	..	.....	..	.....	Adjusted to the top and bottom castings	
145	2	**Spring-compressor channels** (Fig. 398)	8599	W. S.	..	.....	..	6 ft. 2½ in. x 6 in.	To which is fitted	
146	2	**Spring-compressor wearing-plate beams** (Fig. 399)	8005	O.	..	.....	..	6 ft. 7 in. x 5½ in. x 3 in.	Both being then bolted together to the side-sills through holes (j) Fig. 48, Plate IV., with 8 bolts 8¼ in. x ⅝ in.	
147	2	**Spring-compressor wear-plates** (Fig. 405)	8600	W. S.	..	.....	..	.....	Screwed to the wearing-plate beams with 28 No. 16 x 2 in. steel screws, countersunk heads	
148	4	**Truck check-chain hooks** (Fig. 403)	8619	W. I.	..	.....	..	.....	Secured with bolts of the spring-compressor wearing plate beams (8005) Con. No. 146	
149	4	**Angle truck-bearing plates** (Fig. 400)	8597	W. S.	..	.....	..	.....	With

150	4	**Truck rub-plates** (Fig. 401)	8558	W. S.	--	----------	Bolted to side-sills and rubbing-plate beams (5026) Fig. 58, Plate IV., with 8 bolts, 8¾ in. x ⅝ in., through holes (a) and 4 bolts 7⅞ in. x ⅝ in., countersunk heads, through holes (b) Note.—All the pieces described under Con. Nos. 141 to 150 are for use with Brill's Maximum Traction Truck
151	22	**Side-step hangers** (Fig. 395)	8579	W. I.	--	----------	Bolted to the side-sills through holes (g) with 28 round-head bolts 5⅞ in. x ½ in. and 16 round-head bolts 6⅜ in. x ½ in.
152	2	**Side-step tread-boards** (Fig. 387)	8601	Y. P.	--	32 ft. 5 in. x 9¾ in. x 1⅝ in	In 2 pieces, joined together with
153	2	**Side-step splice-plates** (Fig. 393)	8580	S. S.	--	----------	Are now bolted to the step-hanger feet at the notches (a) with 22 round-head bolts 2¾ in. and 22 round-head bolts 2½ in. x 5-16 in.
154	2	**Side-step tread-board facing-irons** (Not Ill)	8581	W. I.	--	33 ft. 0 in. x 1 in. half-oval	Are screwed to the front edge of the tread-boards with 144 No. 14 x 1¼ in. and 4 No. 20 x 4 in. steel screws
155	2	**Side-step toe-guards** (Fig. 389)	8602	Y. P.	--	32 ft. 5 in. x 9¾ in. x 1⅜ in.	Bolted to the legs of the step-hangers with 44 round-head bolts 1 13-16 in. x ¼ in.
156	4	**Side-step hold-up chain and snap** (Fig. 394)	8582	W. I.	--	----------	Screwed to the side-sills with 8 No. 14 x 1 in. steel screws, and
157	4	**Side-step hold-up chain eye** (Fig. 394)	3583	W. I.	--	----------	Bolted to the side-step tread-boards with 8 round-head bolts, 1½ in. x ¼ in.
158	4	**Gooseneck fender-hanger blocks** (Fig. 397)	8007	A.	--	1 ft. 3¼ in. x 6 in. x 3¾ in.	With
159	4	**Gooseneck fender-hangers** (Fig. 396)	8601	W. I.	--	----------	Bolted to crown-piece with 4 cheese-headed bolts 6¾ in. x ½ in. and through the buffer to the platform sills with 4 round-headed bolts, 7¾ in. x ½ in.
160	2	**Dasher-rail caps** (Fig. 384)	8004	C.	--	6 ft. 7½ in. x 2¼ in. x 1 in.	Screwed to the dasher-rails through holes (b) with 12 No. 12 x 1 in. steel screws
161	4	**Platform guard-chains and snaps** (Fig. 381)	8004	W. I.	--	----------	Secured by the eye to the dasher-rails by means of the bolts in holes (c), Fig. 382
162	4	**Platform guard-chain eyes** (Fig. 380)	8605	Bz.	--	----------	Secured to the corner-posts with 8 No. 16 x 1½ in. bronze screws
163	2	**Pedal alarm gongs** (Fig. 378)	8606	S.	--	----------	With
164	2	**Pedal alarm-gong castings and hammer** (Fig. 378)	8607	M. I.	--	----------	Are secured to the floor with 4 bolts 2¼ in. x 7-16 in. and to the crown-piece with 2 bolts 4 in. x 7-16 in.
165	1	**Pedal alarm-gong pin** (Fig. 378)	8608	W. I.	--	----------	Is inserted in hole in nose-piece to operate same
							Assembling has now progressed so far that cabinet work, trimmings, etc., can be next taken up. (*See Table 40, Plate XVI.*) Fig. 195 is reproduced on Plate X., as it shows in position many of the pieces described in this table

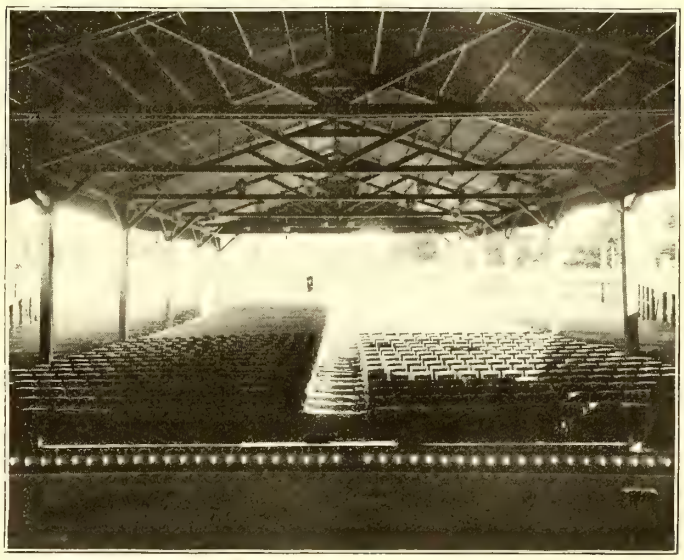
Summer Theater at Syracuse, N. Y.

At some of the recent national and State street railway conventions some doubt has been expressed by certain street railway managers as to the profit of engaging theatrical troupes as attractions to summer railway parks. That this is not the sentiment of all managers, however, is shown by the number of very tasteful and commodious summer theaters which have been built and operated at



INTERIOR OF THEATER

many railway parks throughout the country during the past season. A number of these have been illustrated in recent issues of this paper, and below will be found several views of the theater built this season by the Syracuse Rapid Transit Railway Company.

The theater was opened July 2 and contains about 1000

VIEW OF VALLEY THEATER AFTER PERFORMANCE, JULY 28

seats. It is provided with a roof, so that the entertainment can be given rain or shine. A stock opera company of twenty-seven people was engaged through a musical bureau in New York, and repertoire opera is given, the bill being changed every week. The opera for the first week was the "Mikado."

Conductors sell tickets for 25 cents, including the round-trip car fare and admission to the opera. Persons who do not ride on the cars to the theater have to pay

25 cents admission. The best seats, which consist of 400 opera chairs, are sold at 25 cents extra. Matinee performances are given on Wednesday and Saturday afternoons, when the general admission is 10 cents. During the first two or three weeks in July the weather was very much against open-air performances on account of rain nearly every day and cold nights, but still with the inclement weather the attendance was good. The business, however, steadily increased, and during the last part of July and the first two weeks in August the gate receipts of the show paid the expenses of the theater, making the car fares clear profit.

The plan was a new one for Syracuse, but it has fully established itself in the minds of the people and the very best people in the city are regular attendants. The park is run in a very high-class manner; no intoxicating drinks are sold within the inclosure, and the managers of the company have now no doubt as to the success of the venture. Besides the direct return from the investment there is also no doubt but that the high character of the performances and the splendid car service to and from the show have been the means of improving the standing of the street railway company with the public and making it more popular.

Important Work in Northern New Jersey

The New Jersey & Hudson River Railway & Ferry Company, which operates an electric line from Hackensack and Englewood to Edgewater, N. J., and a ferry between Edgewater and West 130th Street, New York, has been engaged during the last year upon important extensions to its line. A full description of the Hackensack division, about 3 miles in length, was published in the Street Railway Journal of February, 1900. This section has recently been completed by the opening of a large swing-draw across the Hackensack River, giving an entrance to Hackensack. As this bridge is one of the largest, if not the largest drawbridge in the country, used exclusively for electric railway service, it is worthy of more than passing notice. It was built by F. R. Long & Company, contractors, under the supervision of Ford, Bacon & Davis, consulting engineers of the Railway & Ferry Company.

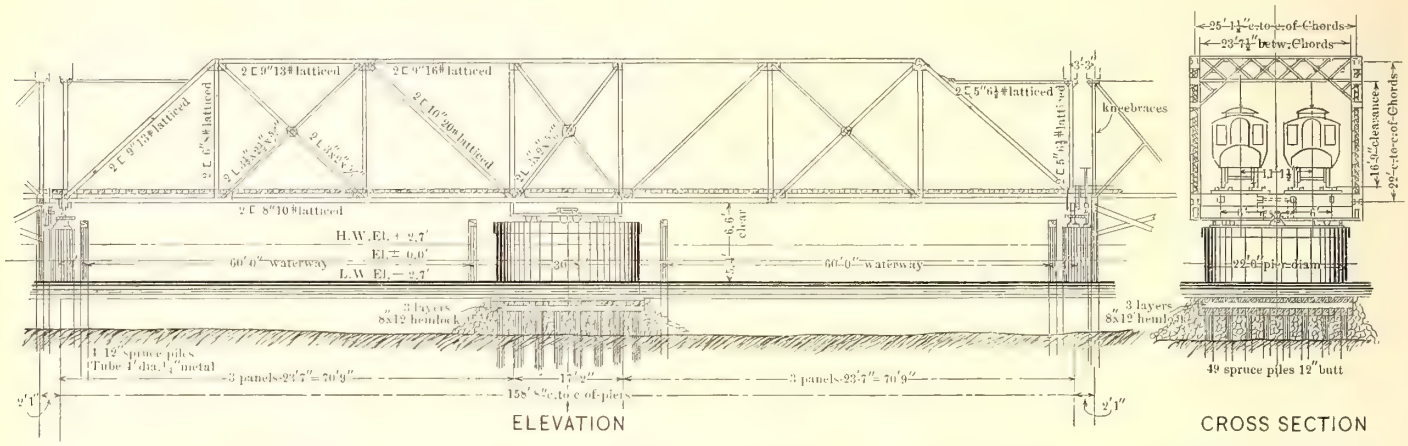


FIG. 2.—SIDE ELEVATION AND CROSS SECTION OF BRIDGE ACROSS THE HACKENSACK RIVER

The approaches to the draw are over trestles at each end. The west side trestle is 915 ft. in length, consisting of sixty-one bents of 15 ft. each. The eastern trestle is 285 ft. in length, and consists of nineteen 15-ft. bents. A standard bent is shown in Fig. 1. The piles, of which there are six in each bent, are all of selected white oak, from 30 ft. to 45 ft. in length. The framing is of long leaf yellow pine, and consists of caps 12 ins. x 12 ins.; girders, of which there are four underneath the track, 8 ins. x 12 ins., and cross and longitudinal bracing, which is 3 ins. x 10 ins. The bracing is bolted and the caps are fastened to the piles by iron dowels. These dowels are 1 in. in diameter, and average from 18 ins. to 24 ins. in length. The holes to receive them were bored 1-16th in. smaller than the dowels, which were covered with white lead and then driven into the hole.

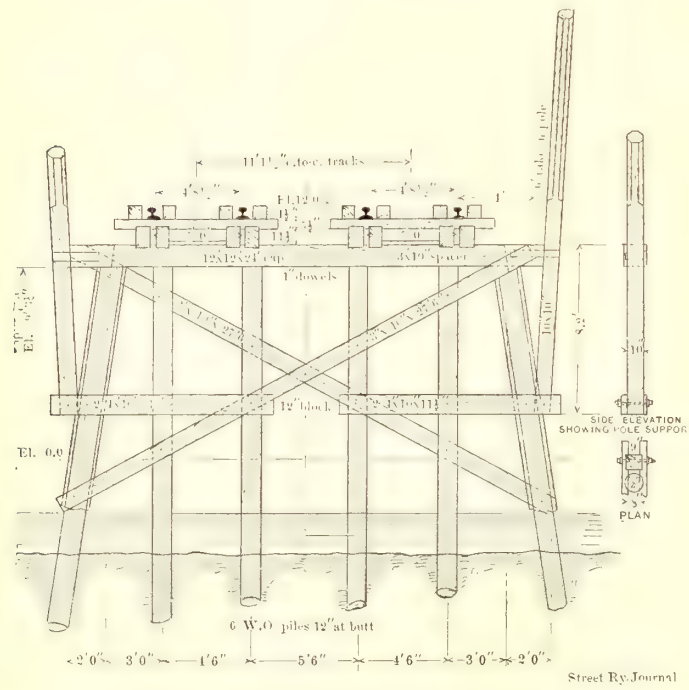

FIG. 1.—STANDARD BENT IN TRESTLE

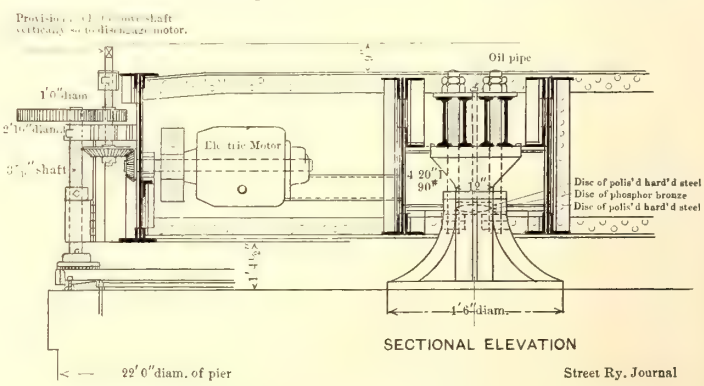

FIG. 3.—ELECTRIC ATTACHMENT FOR OPENING DRAW

The ties and wooden guard stringers are also of yellow pine, the ties being 6 ins. x 8 ins. x 9 ft., and placed 18 ins center to center. The rail is a 60-lb. T. A. S. C. E. standard, with six-bolt joints. The joints are bonded under the fish-plates, and the rails are cross-bonded every six joints. The bridge itself is of the riveted truss type, 160 ft. long, with pivot draw. The center pier consists of piling, on which is a grillage, surmounted by heavy first-class masonry. The end piers are formed by clusters of four piles, each surrounded by a steel casing, 4 ft. in diameter, and filled with best quality concrete. The cross section of the bridge shows the spacing of the tracks, which, as will be seen, is very liberal, to accommodate the extremely wide cars used. The track centers are 11 ft. 1½ ins. apart, permitting two 9-ft.-6-in. cars to pass.

To keep the bridge in line there are four end rests, two on each side; these rests are adjustable from above. In addition, the alignment of the track is kept perfect by the use of four shoes at each end, one of which slides under the ends of each rail, thus holding the latter in line. There are also the usual spring latches. The bridge can be opened by hand or electric power, which is the usual method. For the latter a G. E. 800 motor, with a train of gearing, is used, as shown in Fig. 2, and by it the bridge can be opened and closed in one and one-half minutes. The motor receives its power from a cable connecting the railway feeders with the center pier. The bridge is designed to carry a full load of 30-ton cars on each track.

Special attention was given to the construction of the overhead trolley line on the bridge. As will be seen, the end supports at both the bridge portals and at the shore ends are extremely heavy, being built up of angles, latticed and braced. On the overhead framing, which supports the drawbridge frogs, is attached a short wooden plank, which is backed with an asbestos sheet; the plank was then painted with fireproof and insulating paint. As the frogs which are attached to this board are insulated, a triple insulation is thus secured between the frogs and the iron work of their supports. This substantial construction allows the trolley wire to be kept taut.

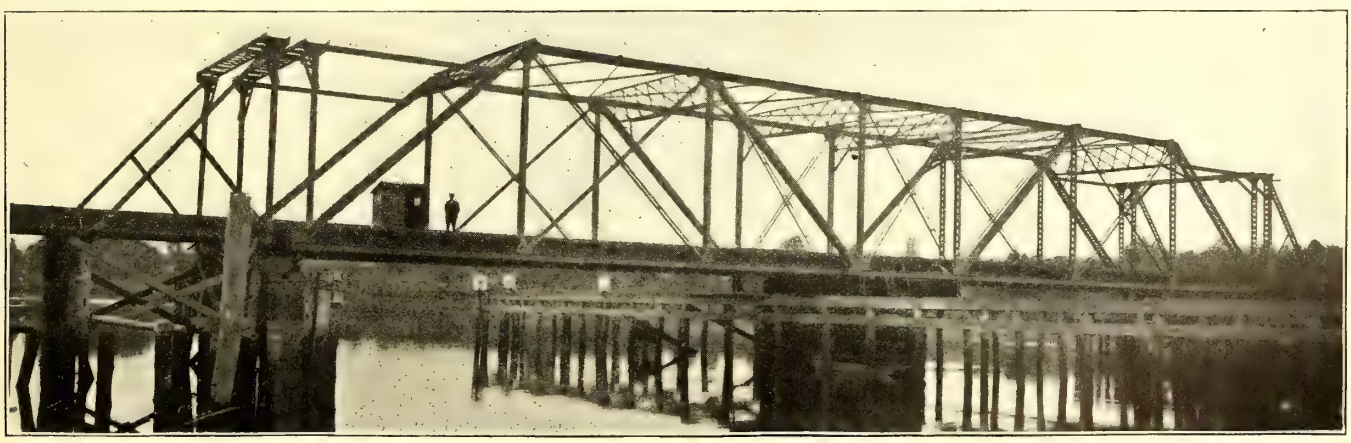
Mention should also be made of the safety devices. Eight hundred ft. from each end of the bridge a cluster of five green lamps, furnished with a reflector, have been installed in a signal box. In addition there are four red lights at a distance of 150 ft. from each bridge portal. Both lamp circuits are closed by the bridge tender just before opening the draw, the lamp near the switch being for the purpose of showing to the tender that the circuits are in working condition. The cars are run over the bridge at full speed.

In addition to the improvements at the Hackensack River, the company has been carrying on other important construction, notably that on the edge of the Palisades, and in the power house, where a 500-kw unit has been installed. A more extended description of these improvements will be published later. The company has also entirely renewed its rolling stock. The closed cars have not yet been delivered, but the open cars have been in use all summer, and are as large and fine as any in use in or near New York. They were designed by Ford, Bacon & Davis, and were built by the American Car Company.

END VIEW OF BRIDGE

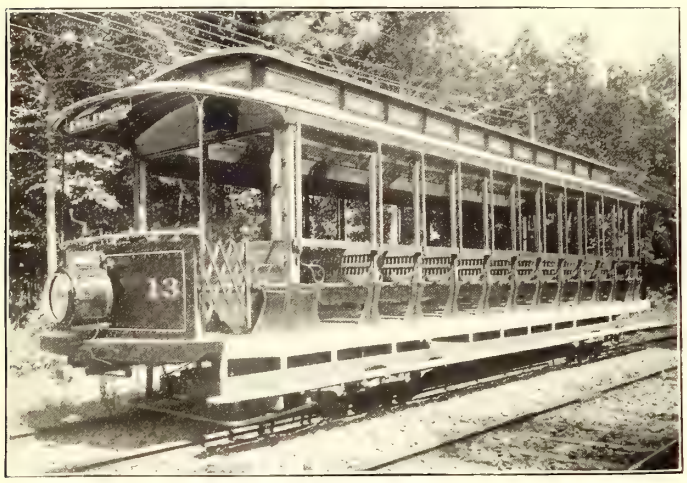
The main dimensions of the open car are as follows: Length over corner posts, 32 ft.; length over dashers, 40 ft.; length over bumpers, 41 ft. 6 ins.; total width over sills, 7 ft. 5⅝ ins.; total width with steps down, 9 ft. 6 ins. The side sills are of long leaf yellow pine, 5 ins. x 7 ins., and each is faced with a ¾-in. x 8-in. continuous steel plate. There is also a regular truss rod for supporting each side sill. The corner posts are of white ash, 4½ ins. x 2½ ins., and all roof rafters are re-enforced with steel.

The interior finish of the car is of white ash, and it is fitted with ten reversible and four stationary benches, each seating six passengers. At the ends of the car are two large windows, the advertising racks over which are reserved exclusively for the notices of the company. The



SIDE VIEW OF 160-FT. SWING BRIDGE

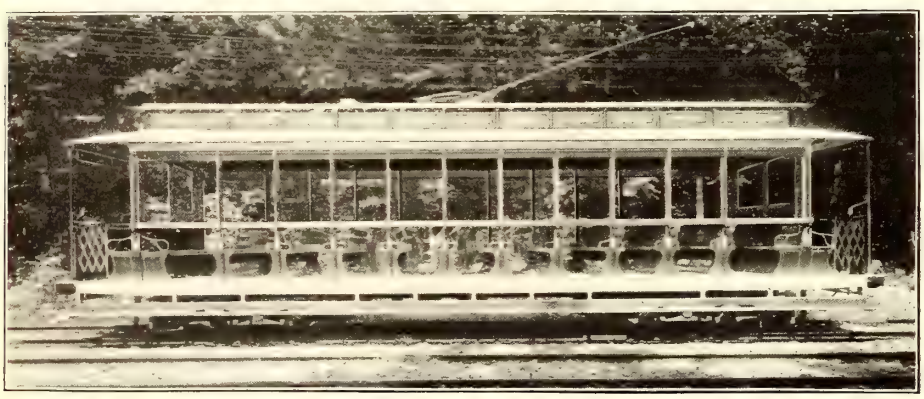
ceilings are of bird's-eye maple. A novelty has been introduced in the electroliers, which are not of metal, but consist of an ornamental wooden cone, carrying sockets in which the lamps are set. This eliminates all danger of crosses, and the cone is much easier to keep in good condition than a metal electrolier. There are three clusters of five lamps each for interior illumination. The bumper is



END VIEW OF CAR

of solid white oak, faced with a ½-in. x 6-in. steel plate. On the roof of the car is a tool box, in which all miscellaneous repair parts are kept, and between the trolley boards is an extra trolley pole. This precaution has been found useful on more than one occasion. The cars are furnished with arc electric headlights, and are also equipped with Vandorn draw-bars, Sterling fenders and registers, Wilson trolley catchers, De Witt sand boxes and the Price momentum brake, manufactured by the Peckham Truck Company.

The subject of braking is a very important one upon this line, as the cars have carried as many as 160 passengers



SIDE VIEW OF CAR

each, and would weigh, when loaded with 200 passengers, 30 tons each. At the same time the line is almost a succession of grades, some of which are as high as 10 per cent, with sharp curves at the base. The managers of the road state that the brakes have given great satisfaction, and are very easy to operate and keep in repair.

Each car is mounted on two 14 B 3 Peckham trucks, with 4-ft. wheel base. Double plate wheels, supplied by the New York Car Wheel Works, are used; they are 30 ins. in diameter, with 3¼-in. tread and 1-in. flange. The motor equipment consists of four G. E. 67 motors, which have a rating of 38 hp each. These motors have no difficulty in carrying the car up the grades, and as an instance of the load which comes upon them, it might be stated that it is not an uncommon thing for one car to draw more than 350 amps. from the line.

Owing to the fact that the cars are wider than those which had previously been used on the line and the fact that in the summer large loads are often carried, it was considered advisable to run a car over the line early in the season, with different loadings, to determine the compression at the different loads, together with the permanent set. The load was secured by filling large paper bags with sand. These bags weighed 81 1-3 lbs. apiece, and with the full loading, eight bags were placed in each seat. The test was a severe one, being more than a car would actually carry in passengers, and the load being more dead than a human load would be. Some of the results of this test, which was made by F. W. Bacon, general superintendent of the Railway & Ferry Company, are given in the following figures:

AVERAGE COMPRESSIONS
(All measurements made from bottom of sills.)

Car Body

Load, 10,000 lbs. compression	17/32 ins.
" 20,000 " "	1 9/16 "
" 25,000 " "	2 3/8 "
Permanent set	7/32 "

Journal Springs

Load, 20,000 lbs. compression	3/16 ins.
" 25,000 " "	10/32 "
Permanent set	1/32 "

(Not including journal spring, that came up ⅛ in.)

Average rise of bolster from 25,000 lbs. to no load.... 1 7/32 ins.

Storage Battery Cars in New York

The Metropolitan Street Railway Company, New York, is now operating four storage battery cars on its Thirty-Fourth Street crosstown line. There are several quite severe grades on this line, but the cars are giving perfect satisfaction, and as fast as more can be secured they will be used to replace the horse cars still in use. The cars are of a large closed type, similar to that of the Broadway cars, room being found for the batteries beneath the seats. The motors and controllers, furnished by the General Electric Company, differ somewhat from those used on the other cars of the Metropolitan electric lines. The type of motor is G. E. 72, and of controller, S-7. A complete charging station has been fitted up at the car house in Forty-Second Street, and the system is expected to satisfactorily supply the needs of crosstown traffic in that section of the city.

The date of opening the entire Broadway line with electric power has not yet been announced, although Mr. Vreeland has stated that the line as far south as the postoffice would be completed, so far as street excavation is concerned, about Sept. 1. All of the Lexington and Columbus Avenues cable lines have been altered. On the latter lines the existing track rails were not changed, but the joints were cast-welded by the Falk process.

The rearrangement of the transfer system in Washington, D. C., and the curtailment of its privileges has met with some opposition from the residents of the city. The inauguration of a double fare on one of the lines of the system has also met with a storm of protests. However, the opposition comes mainly from those who "kick for the sake of kicking." President Stevens, of the company, has given ear to all with supposed grievances, and has convinced the general public of the merits of the new system.

LEGAL NOTES AND COMMENTS

EDITED BY J. ASPINWALL HODGE, JR., OF THE NEW YORK BAR*

Conflicting Decisions on a Question of Contributory Negligence

A New York Appellate Court has just passed upon a legal proposition never before decided in this State, and in doing so has followed a decision in Iowa, which it cites, and decisions in Virginia and Ohio which it does not cite. It expressly repudiates the reasoning by which the courts of Tennessee, Illinois, Missouri, Maryland and Texas have reached an opposite conclusion.—*(Lewin vs. Lehigh Valley Railroad, 52 App. Div., 69.)*

The court holds that, in an action brought by an administrator to receive damages for the next of kin caused by the negligence of the defendant, the negligence of the administrator, who was the father of the infant intestate, contributing to the fatal injuries is not a defense; and that this is so, although the administrator is the sole next of kin and under the statute entitled to the entire proceeds of the action. The court cites the case of *Wymore vs. Mahaska Co., 78 Iowa 396.* The same doctrine is held in *Norfolk R. R. vs. Groseclose, 88 Va., 267,* and in *Cleveland R. R. vs. Crawford, 24 Ohio St., 631,* and *Davis vs. Guarmieri, 45 Ohio St., 470.*

The theory of these cases cannot be defended on the ground that exact or even approximate justice is done, but only on the ground that the action, being created by a statute, the question is not what is justice and right between the parties—the answer to which solves most questions of common law when unaltered by statute—but rather what is the wording of the legislative enactment. Where that says that the administrator shall recover in all cases where the intestate could have recovered had he survived, it must mean that this defense, involving the negligence of a third party—although the party benefiting by a recovery—cannot be successfully interposed. Practical difficulties the court sees, which would arise under any other construction, and which are wholly unprovided for by the statute. For example, if there were several beneficiaries, some of whom were negligent and some were not, how would the fund awarded be distributed?

But the court had difficulties to meet, on the other hand, when confronted with the proposition that its decision was allowing one to profit by his own wrong, a result repugnant to the law. The court only half answers that objection by saying that that proposition applies only to cases where the party's wrong is *wilful,* as where one murdered his grandfather and was not allowed to take under his will. But suppose the act of the father administrator which contributed to the accident was a wilful one, or suppose the act was a joint assault upon the intestate. All the reasons deduced from the wording of the statute for holding that the plaintiff administrator could recover would hold good, including the dreaded complications in distributing the fund, if there were innocent, as well as guilty, next of kin. The court probably felt that this effort to reason away the strength of this maxim prohibiting a profiting from one's own wrongdoing was only partially successful, for it immediately makes the bolder and the safer statement that the court is not concerned with the final disposition of the fund—that is not a part of the proceedings prior to judgment.

There can be no question, whatever view we take of the decisions in the above mentioned States, that the statutes which necessitate or allow them need revision. In the January and February numbers of the STREET RAILWAY JOURNAL we pointed out other analogous evils, and injustices which are the progeny of the carelessly constructed statutes governing this form of action by an administrator for the next of kin.

All the courts of other States which have passed upon this question have taken the opposite view, and held that the negligence of the next of kin who could benefit by the recovery may be proved as a defense to the action.—*(Bamberger vs. R. R., 95, Tenn., 18; City of Pekin vs. McMahon, 154 Ill., 141; Koons vs. R. R., 65 Mo., 592; B. & O. R. R. vs. State, 30 Md., 47; T. M. R. & M. N. Co. vs. Herbeck, 60 Tex., 602.)*

It will be noticed that this question is not one like that which is still waged about the doctrine of imputed negligence. There is involved simply a difference of opinion upon a question of abstract justice, to wit: Shall the negligence of a parent be visited upon the head of an innocent child where such negligence has contributed to the accident to the child damaged? New York was the first to say "Yes" *(Hartfield vs. Ropes, 21 Wend., 615),* and was followed by Massachusetts, Maine, California, Minnesota, Maryland and Indiana, and withstood and contradicted by the courts in nearly all the other States and in England. There the difference of opinion is in the answers to the question, what is just? But in the case we have been discussing the courts do not disagree upon that question at all. They, none of them, hold that it is just that next of kin whose negligence has contributed to the death of the intestate should recover, but some of them hold that the statute compels them to decide contrary to the justice of the matter.

Where a father brings an action for the loss of services of an infant the courts all agree that if his negligence contributed to the accident caused by the negligence of the defendant, he cannot recover.—*Smith vs. Hestonville R. R., 92 Penn St., 450; Metcalf vs. Rochester R. R., 12 App. Div., 147, 158.* This illustrates curiously the injustice of New York, Iowa, Virginia and Ohio (whether necessary under the statutes or not), in the cases brought by administrators.

A father with his child in a carriage is run into by a train and his carelessness is a contributing cause of injuries sustained by the child. The injuries seriously threaten the child's life. They are certain to incapacitate it for work. Whether the child shortly dies as the result of the injuries or lives, incapable, the father has lost the child's services during its minority. If the child dies he can recover damages for such loss (and other damages as well) under the doctrine in *Lewin vs. R. R., supra;* but if it lives he cannot recover under the doctrine in *Metcalfe vs. R. R. supra*—as he should not in either case—because he brought the damage upon himself by his own carelessness, which may have been almost criminal. H.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

CONNECTICUT.—Injunction—Franchises—Power to Lease—Damages—Legal Action.

1. Where defendant's answer, in an injunction proceeding to restrain it from trimming certain trees, alleged that such trimming would not materially injure the trees, a demurrer by plaintiff to such answer admitted the truth of its allegations, and was decisive against plaintiff, since an injunction does not issue to prevent immaterial injury.

2. 5 Sp. Laws, 619, 10 Sp. Laws, 69, 11 Sp. Laws, 1082, and 12 Sp. Laws, 208, 682, authorizing defendant company to take leases of the property and franchises of any other street railway companies with which its tracks may connect, imply power in the latter to give such lease; and, where defendant was a lawful lessee of a franchise to construct and operate a street railway, averments in its answer that it had a right to lay and operate such railway were sufficient statements of its power to do so.

*Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

3. Where a bill for injunction is based on a threatened injury to trees, and no case is made justifying the issuance of the writ, plaintiff cannot recover damages in lieu thereof before the injury is done.—(Huntington vs. Hartford St. Ry. Co., 46 Atl. Rep., 824.)

ILLINOIS.—Charter Powers—Method of Operating—Changes—Parties Entitled to Question. A declaration charged that defendant was authorized by its charter and a municipal ordinance to operate its street cars in a city by means of animal power only; that one of defendant's cars, while being operated by cable power, collided with one of plaintiff's cars, and injured it. It was not alleged that the collision was occasioned by the negligence of defendant's employees in charge of such car. Held, since the question of whether the propulsion of defendant's cars by cable power was an abuse of its charter powers can only be determined in direct proceedings instituted by the State or city, the adoption and use of such power cannot, in an action between individuals, be adjudged of itself to make defendant a trespasser in the street so as to make it liable for injuries not occasioned by its negligence.—(Chicago Gen. Ry. Co. vs. Chicago City Ry. Co., 57 N. E. Rep., 822.)

ILLINOIS.—Eminent Domain—License—Res Judicata.

1. Rev. St. c. 24, art. 5, sec. 1, par. 25, provides that City Councils shall have the power to establish and change the location of any railway within the city. Chap. 131a, sec 2, declares that, when it is necessary for the construction, maintenance, or operation of any street railway to take or damage private property, such taking may be accomplished as exercise of right of eminent domain. Held, that where a city passed an ordinance which claimed to be by authority of chap. 24, and which declared that a certain street railway should locate its line in certain streets and on certain private property, the ordinance was a nullity so far as establishing a route for the railway was concerned, as the taking of private property is authorized only in case of necessity, under the statute, and not upon the judgment of a City Council.

2. Rev. St. c. 24, art. 5, sec. 1, par. 25, provides that City Councils shall have the power to establish the location of any railway within the city. Chap. 131a, sec. 2, declares that, when it is necessary for the construction or operation of any street railway to take or damage private property, such taking may be accomplished as exercise of the right of eminent domain. Held, where a city ordinance declared where the lines of a street railway might be located, and provided it should be located on no private property without the consent of the owner, the ordinance was a nullity as a location, since the railway company was not authorized to adopt the location by virtue of the ordinance, or upon proof of the necessity contemplated by the statute.

3. Where an ordinance declared that a street railway might locate its lines on certain streets and over certain property, and then provided that the location was to be made subject to such further conditions as might be imposed by ordinance when the railway company should adopt the route, and that the ordinance was not to be construed as a grant of rights in any street, but that the determination whether such right should be granted was reserved until a petition for the same should be presented by the railway company, the ordinance was a nullity as a location, in that there was no grant of a right to go upon or along the streets on which the ordinance professed to provide for location.

4. Rev. St. c. 24, art. 5, sec. 1, par. 25, provides that City Councils have the power to establish the location of any railway within the City. Chap. 131a, sec. 3, relative to street railways, provides that no assent shall be granted of the location of the line of the street railway until public notice of the road's petition for a location shall be first given by ten days' publication in some newspaper. Held, that where a city passed an ordinance which declared that a street railway company might locate its line on certain streets without there having been a petition or publication of the notice thereof, the ordinance was a nullity as a location.

5. Where a city gave to a street railway company the right to use certain streets on the condition that the road should grade and gravel the street, and pay $100 a year for a term of years, and the road accepted the burdens and expended $3500 in complying with the conditions, and built its road in the street, an ordinance thereafter passed, prohibiting the occupation of part of the streets occupied, was a nullity, since the license having been acted on, and a substantial consideration received by the city, the license became a binding contract.

6. Where, on proceedings by a street railway company to condemn private property, owners of such property contested the company's right to condemn the same, and the questions raised were taken to the court of last resort, the decision of that court concerning the company's right to take the property settled every objection which might have been raised, whether then raised or not, since the doctrine of *res judicata* embraces, not only what has been actually determined, but extends to any other matter which might have been determined.

7. It is not necessary, as a condition precedent to the location by a street railway company of such portions of its line as are not within, upon, or across a street, nor to the exercise of the power to condemn private property for purposes of its construction, that the consent of the city be obtained, as that may be secured subsequently.—(Harvey et al. vs. Aurora & G. Ry. Co., 57 N. E. Rep., 857.)

KANSAS (United States Circuit Court of Appeals).

1. Appeal—Formal Error as to Parties—Amendment. The fact alone that an action was brought in the name of the wrong party as plaintiff is not ground for reversal, but the Appellate Court will direct the substitution of the proper party.

2. Private Nuisance—Use of Street by Railways—Legislative Authority. Neither by legislative enactment nor by ordinance of a city can the use of a public street be granted to a private corporation for uses which constitute a private nuisance, and result in special injury to the owners of property abutting on the street, except upon making compensation for such injury.

3. Railroads—Grant of Right to Use Street—Construction. A grant to a railway company of the right to "operate and maintain a railway" on a public street does not carry by implication the right to erect and maintain a water tank in the street.

4. Private Nuisance—Use of Property by Railway Company. A railway company has no more right than an individual to so use its property as to unreasonably interfere with the peaceable and comfortable enjoyment by others of their property, or to cause special injury to particular property, without making compensation for the injury.

5. Same—Location of Railway Station Adjacent to Church—Liability for Damages. The erection by a railway company of a water hydrant in a street immediately opposite the center of a church, and only 35 ft. distant, and of a station on property on the opposite side of the street, so that the noises and odors and the dust and smoke incident to the stopping and starting of trains at both station and hydrant interfere with services in the church, and render the building unfit for the uses for which it was built, constitutes a private nuisance, which amounts, in legal effect, to a taking of the church property to the extent of the injury done thereto, for which the company may be required to make compensation; and it is no defense to an action for the recovery of such compensation that the structures built by the company are necessary for the operation of its road, or that its trains are operated in a careful and proper manner.—(Chicago G. W. Ry. Co. vs. First Methodist Episcopal Church of Leavenworth City, Kan., 102 Fed. Rep., 85.)

LIABILITY FOR NEGLIGENCE

ALABAMA.—Personal Injuries—Collision with Hose Cart—Contributory Negligence—Right of Way—Ordinance—Evidence—Instructions—Appeal and Error—Record—Recitals—Assignments of Error—Issues—Waiver.

1. Where the record shows no judgment on either the demurrer to the complaint or the demurrer to the pleas, a statement that a demurrer to each count of the complaint was overruled by the court, and demurrers to pleas Nos. 4, 5, 6, 7 and 8 sustained by the court, is nothing but a memorandum of the clerk, and assignments of error based thereon will not be considered.

2. Where pleas were filed to the complaint, and demurrers were interposed to a part of them, the record failing to show any judgment on the demurrers, they will be regarded as waived; and the judgment entry reciting that "issue being joined," without specifying particular pleas, on appeal it will be considered that issue was joined on all the pleas.

2. Plaintiff, a fireman, was riding on a hose cart driven by the chief driver. The horses were being driven as fast as they could run, and while crossing defendant's tracks collided with a car standing thereon, and plaintiff was injured. There was a car track on the street on which the hose cart was being driven, and crossing the defendant's track. There was a space of about 8 ft. between such track and defendant's car. No effort was made to check the speed of the hose cart as it approached defendant's track. Held, that the manner of driving the hose cart across defendant's track was negligent.

4. In an action by a fireman against a street railway company for injuries received in a collision between a hose cart on which he was riding and one of defendant's cars, an ordinance of the city giving the hose cart the right of way in the street was irrelevant, since having the right would not exempt the driver of the hose cart from the duty of exercising care in driving across defendant's track.

5. Where, in an action for personal injuries, evidence, without conflict, sustained the plea of contributory negligence, it was error to refuse an instruction that, if the jury believed the evidence, they should find for the defendant.

6. In an action by a fireman for personal injuries received in a collision between a hose cart on which he was riding and one of

defendant's cars, an instruction that it did not make any difference in that action whether the driver of the hose cart was negligent or not, unless his negligence was the sole cause of the accident, was erroneous.—(Birmingham Ry. & Elec. Co. vs. Baker, 28 So. Rep., 87.)

CONNECTICUT.—Negligence—Riding on Footboard—Judgment by Default—Nominal Damages. Where a street railway was built along a causeway, which necessitated placing the trolley poles near the track, and defendant, who had knowledge of the situation, was riding on the footboard next to the trolley poles, and refused to step up on the platform at the invitation of the conductor, but leaned back to allow him to pass by, and struck his head against a trolley pole, plaintiff was entitled to nominal damages only on default, since he was guilty of contributory negligence.—(Nugent vs. Fair Haven & W. St. Ry. Co., 46 Atl. Rep., 875.)

ILLINOIS.—Jumping on Moving Car—Proof of Custom—Encouragement of Custom—Negligence *per se*—Circumstances—Instruction—Province of Jury.

1. Where, at the transfer station from defendant's electric line to their cable cars, the latter were started by the car-house cable, and were carried by their own momentum a distance of 50 ft., to where the down-town cable was picked up, and the plaintiff, who had run after a car while it was moving slowly of its own momentum, and stepped on the platform, was thrown and injured by the sudden jerk occasioned by the picking up of the down-town cable, evidence that passengers during the crowded travel of the morning hours were in the habit of running after the cars and jumping on them at that point was incompetent for the purpose of establishing a standard of ordinary care.

2. Evidence that it was the custom of passengers during the crowded travel of the morning hours, to so run after and jump on the cars, and that the defendant's conductors encouraged them in so doing, by assisting them on the car and telling them to come on, was competent to show negligence on the part of the defendant.

3. An instruction that the court did not mean to give an opinion as to what were or were not the facts in the case, but that it was solely and exclusively for the jury to determine from the evidence, and having done so to apply to them the law as stated in the instructions, was not objectionable as giving the jury to understand they were independent of the law.—(North Chicago St. Ry. Co. vs. Kaspers, 57 N. E. Rep., 849.)

MINNESOTA.—Collision with Traveler—Contributory Negligence.

1. The reciprocal relations of the public and a street railway company vary according to circumstances and conditions. Distinction made as to their relative rights and duties in the populous and in the sparsely settled parts of a city. Held, that the driver of a vehicle who drove upon a street railway track in the suburban, thinly settled district of a city, where the public use of the street was limited, without looking for approaching cars, was guilty of negligence.

2. One who, under such conditions, is riding in a rear seat, and who has no direct control over the horses at the time, but who is a joint contributor to the hire of the team for the occasion, is guilty of negligence if he does not look for approaching cars upon crossing a street car track.

3. Under the circumstances of this case, a mere passenger, who has no control over the team, was not guilty of negligence in failing to look out for cars when crossing the track.

4. Certain assignments of error examined and held to be not sustained.—(Wosika vs. St. Paul City Ry. Co.; Shindelus vs. Same, 83 N. W. Rep. 386.)

MINNESOTA.—Injury to Person on Track—Question for Jury.

1. As a general rule, it is a question of fact for the jury, to be determined from all the circumstances of each case, whether a party is guilty of negligence in attempting to cross a street railway track without first looking and listening for approaching cars.

2. Rule applied, and held, that the question of the plaintiff's contributory negligence in this case was one of fact and not of law.—(Riley vs. Minneapolis St. Ry. Co., 83 N. W. Rep., 376.)

MINNESOTA.—Accident to Person on Track—Evidence. This is a personal injury action. The plaintiff, in the nighttime, was thrown from his bicycle upon the street car tracks of defendant, and thereby rendered unconscious. While in this condition he was struck and injured by one of the defendant's cars. One of his specifications of negligence was that the defendant permitted the headlight of the car to become defective, dirty and grimy, so that it did not sufficiently light its tracks. A witness who was present at the time of the accident was permitted to testify that subsequent thereto, and for a year, he observed the headlights on other cars of the defendant at different times and under different conditions, and that they gave a better light, and showed further on the tracks, than did the one in question on the night of the accident. Held, prejudicial error.—(Moldenhaur vs. Minneapolis St. Ry. Co., 83 N. W. Rep., 381.)

MINNESOTA.—Collision with Wagon—Evidence—Damages. These are personal injury actions. Held, in each case:

1. That the finding of the jury to the effect that the defendant was guilty of negligence, and the plaintiff was not chargeable with contributory negligence, is sustained by the evidence.

2. That the amount of damages in one of the cases is excessive.—(Durose vs. St. Paul City Ry. Co. [three cases], 83 N. W. Rep., 397.)

MISSOURI.—Injury to Pedestrian—Contributory Negligence—Violation of Ordinances—Civil Liability—New Trial.

1. A decedent's contributory negligence will bar a recovery of damages for causing his death, in the absence of allegations and proof of wantonness or wilfulness in causing the injury, though defendant may have been negligent.

2. Where a verdict is in accordance with the law, the granting of a new trial is error, though the court committed error in refusing instructions.

3. The violation of a city ordinance requiring a motorman to keep a vigilant watch for persons on or moving toward the track, and on the first appearance of danger to stop the car in the shortest time possible, and prescribing a penalty for failure to comply therewith, will not authorize a recovery against the company for causing the death of a person on the track, without proof that such company had agreed to or contracted to be bound by such ordinance, since the city cannot by ordinance create a right of action between third persons, nor enlarge the common-law liability of citizens between themselves.

4. Where a city ordinance regulating the operation of street cars is not enacted for the special benefit of any person or class of persons, but simply pertains to the conduct of the companies to the community as a whole, no other liability follows a violation than the penalty imposed by the ordinance itself, and hence its violation confers no right of action by third persons.—(Holwerson vs. St. Louis & S. Ry. Co., 57 S. W. Rep., 770.)

NEW JERSEY.—Appeal — Review — Conflicting Evidence—Comments by Court.

1. When the evidence of witnesses in a cause on trial is in conflict, it is the province of the jury to determine which of it is to be taken as true—to determine the credibility of the witnesses, and in which direction the weight of evidence exists; and the verdict will not be set aside unless it be against the clear weight of evidence, or is found to be the result of the feeling, bias or prejudice of the jurors.

2. Comments of the trial court upon the evidence, fairly made, and which do not mislead the jury, if the facts be left to the jury to determine for themselves, will not be cause for setting aside a verdict.—(Faulkner vs. Paterson Ry. Co., 46 Atl. Rep., 765.)

NEW JERSEY.—Collision—Injuries—Negligence of Motorman—Verdict—Evidence. Where it appeared that, when plaintiff drove onto defendant's street car track, its car was several hundred feet away, and nothing prevented the motorman from seeing him, though the track was slippery, a verdict in his favor for injuries sustained in a collision with the car will not be set aside.—(Sickler vs. North Jersey St. Ry. Co., 46 Atl. Rep., 779.)

NEW JERSEY.—Injury to Driver of Wagon—Contributory Negligence. One who, while driving on a street in front of an approaching street car, turns his team onto the track in front of the car without turning around to see whether or not a car is approaching, and is struck by the car for the reason that it is too near him to be stopped after his intention to drive onto the track becomes apparent, is guilty of contributory negligence.—(McHugh vs. North Jersey St. Ry. Co., 46 Atl. Rep., 782.)

NEW JERSEY.—Injury to Child on Track—Contributory Negligence.

1. The rule of duty which requires the ordinary traveler in crossing a street railway to use his powers of observation to discover approaching vehicles, and his judgment how and when to cross without collision, is also binding upon a child who is *sui juris*.

2. In actions for injury to a child of that degree of responsibility when so crossing a street railway, the question of contributory negligence is generally one for the jury; but where it appears beyond dispute that the child, in its attempt to cross, acted in entire disregard of the degree of prudence which may be reasonably expected from one of his years, and has thereby contributed to the collision that caused the injury, then the question, contrary to the usual rule, becomes one for the court to determine.

3. In the present case the plaintiff was a girl nine years of age, who was in the act of crossing a trolley track in a city street, and was injured by collision with an approaching car. Under the circumstances, as developed by the plaintiff's evidence at the trial, a nonsuit was granted. On error, held, that the nonsuit should be

sustained on the ground of contributory negligence.—(Fitzhenry vs. Consolidated Traction Co., 46 Atl. Rep., 698.)

NEW JERSEY.—Assault on Passenger—Damages. Plaintiff, while a passenger on a street car, was assaulted by the conductor and thrown from the car. After the assault he was not able to work for eight weeks, and since then only able to work eight hours a day, and earn $8 a week. Before he was assaulted he worked from twelve to fourteen hours a day and earned from $10 to $18 a week. He received a slight scalp wound, had a rib fractured, spit a little blood, and suffered a great deal of pain. His physician stated that thirty-three days after the injury he was apparently cured, and that his bill was $62. The jury awarded plaintiff $2500. Held, that the damages were excessive and should be reduced to $1200.—(Fohrman vs. Consolidated Traction Co., 46 Atl. Rep., 783.)

NEW JERSEY.—Carriers—Degree of Care—Crowding Trolley Car.

1. A common carrier of passengers must use a high degree of care to protect them from dangers that foresight can anticipate.

2. By "foresight" is meant not foreknowledge absolute, nor that exactly such an accident as has happened was expected or apprehended, but, rather, that the characteristics of the accident are such that it can be classified among events that, without due care, are likely to occur, and that due care would prevent.

3. The crowding of a trolley car, and especially of those parts of it that are used for entrance and exit, is attended with a liability to danger that the carrier should anticipate and employ care to avert.—(Hansen vs. North Jersey St. Ry. Co., 46 Atl. Rep., 718.)

NEW YORK.—Injury—Conflicting Evidence. In an action for injuries caused by being thrown from a moving street car, where the evidence of plaintiff and defendant was conflicting, a nonsuit was properly denied.—(Kelly vs. Brooklyn Heights R. Co., 64 N. Y. Suppl., 64.)

NEW YORK.—Liability for Injuries—Streets—Contract to Maintain.

1. Where a street railway company contracted with a township to keep the streets and highways in a safe and passable condition, while constructing its road, an action for an injury resulting from the dangerous condition of the highway, may be maintained against the company by the person injured.

2. Same—Sufficiency of Evidence. A street railway company had contracted with a township to keep the streets and highways in a safe condition while constructing its road therein. Plaintiff was injured by reason of the unsafe condition of such road. The evidence for the plaintiff showed that the company had not worked on the line for two months, while defendant's witnesses testified that it had been completed for six months. Held, insufficient to support a finding that the road was being constructed at the time of the accident, so as to entitle plaintiff to recover against the company.

3. Motion to Dismiss—Waiver. Where defendant moved to dismiss the complaint for insufficiency of evidence, at the close of plaintiff's case, and stated wherein the evidence was insufficient, and such deficiencies were not supplied, defendant did not waive the right to insist that the cause should not be submitted to the jury by failing to again specifically set out the grounds of the objection in a motion to dismiss, which was made after the evidence was closed.—(Sullivan vs. Staten Island Elec. R. Co., 64 N. Y. Suppl., 91.)

NEW YORK.—Evidence—Speed of Car—Competency of Witness.

1. A witness who has driven wagons for twenty years, and who testifies that he is familiar with the speed of wagons, is competent to testify as to the rate of speed at which a street car was running at a particular time, and which he had a chance to observe.

2. Same. It is not error, in an action for injuries sustained by collision with a street car, to refuse to permit a witness to state whether a car was running fast or slow, where he states that he did not notice its speed.—(Garduhn vs. Union Ry. Co., of New York City, 64 N. Y. Suppl., 210.)

NEW YORK.—Review—Sufficiency of Evidence.

1. Where there is evidence in the record sufficient to sustain the judgment of the trial court, it will not be reversed on appeal as against the weight of the evidence.

2. Permanent Injuries—Damages—Instructions. Where, in an action for injuries resulting from defendant's negligence, plaintiff testified that his memory had been impaired by the injury, and a physician testified that loss of memory was a reasonably certain result of such injury, it was not error to refuse to instruct that no damages could be had for permanent injuries.—(Jena vs. Third Ave. R. Co., 64 N. Y. Suppl., 88.)

NEW YORK.—Negligence of Independent Contractor—Liability—Joint Tort Feasors.

1. Plaintiff was injured by the upsetting of a carriage caused by an embankment from 4 ft. to 7 ft. high, which had been thrown up in the public highway by the defendant contractors under a contract with the defendant railway company, preparatory to building an elevated roadway over the defendant company's track. On the night of the accident there was no light to warn travelers of the presence of the embankment. The Supreme Court had authorized the railway company to build the roadway, and also ordered the company to comply with the requirements of General Railroad Law, sec. 11, which authorizes railway companies to excavate, fill in, or change the grade of a highway when necessary to carry its line across the roadway. Held, that the defendant railway company was liable for the injury, as a joint tort feasor, and could not escape liability under the rule that exempts a party from damages for the negligent act or omission of an independent contractor, who has undertaken work for the benefit and at the instance of the party with whom he contracts; since the railroad company, having interfered with the highway under the permission of a statute, had imposed on it the implied obligation to protect the public from accidents by reason of such interference.

2. Same—Excessive Damages. Where plaintiff was thrown from a carriage and seriously injured, by reason of which she was confined to her bed for many weeks, and used crutches for three months after the accident, and eighteen months thereafter had not fully recovered, and probably never would be completely restored to health, a verdict of $8000 was not excessive.

3. Instructions—Co-Defendants. Where a requested instruction related wholly to the respective rights of the co-defendants, and had no bearing on the rights of the plaintiff, a judgment in favor of the plaintiff will not be reversed because of the refusal to give such instruction.—(Deming vs. Terminal Ry. of Buffalo et al., 63 N. Y. Suppl., 615.)

NEW YORK.—Collision with Team—Negligence. A finding that a collision of street car with a wagon at the intersection of two streets was caused by negligence of the motoneer, without contributory negligence of the driver, is warranted by evidence that the driver, on coming east from a point 10 ft. from the west crossing, saw the car coming south 100 ft. from the north crossing; that while driving the team at a "moderate trot," without lessening his speed as he approached the track, and "looking for other vehicles and pedestrians that might be on the other crossing," the wagon was struck on the hind wheel by the car; and that the motorman gave no warning of the car's approach, and made no effort to check its speed, though he saw the team as he approached the northerly crossing, and could have stopped the car within 12 ft.—(Piercy et al. vs. Metropolitan St. Ry. Co., 62 N. Y. Suppl., 867.)

NEW YORK.—Credibility of Witness—Hostility.

1. In an action against a railway company for injuries, the fact that a witness for plaintiff, who was also her attorney, had, as an attorney, brought other actions against defendant, is not sufficient to show that, as a necessary consequence, he must entertain malice against defendant sufficient to affect his credibility as a witness.

2. Same—Appeal—Harmless Error. The sustaining of objections to questions put to a witness introduced by plaintiff, who was also plaintiff's attorney, tending to elicit evidence of his hostility to defendant from the fact that as attorney he had prosecuted other actions against defendant, if error, was not prejudicial, where the witness' hostility was made manifest by other evidence.—(Franklin vs. Third Ave. R. Co., 65 N. Y. Suppl., 434.)

WISCONSIN.—Judgments—Verdict—Contributory Negligence—Duty to Look and Listen.

1. A decision of the Supreme Court in an action by a wife alone for personal injuries will, under the rule of stare decisis, control a subsequent action of the husband to recover for the same injuries, in so far as there is a substantial identity in each case.

2. It is not error to direct a verdict for defendant in an action against an electric street railway company to recover for injuries sustained by one of defendant's cars, where there is no direct evidence of defendant's negligence, but there is evidence showing plaintiff to be guilty of contributory negligence.

3. A motorman on an electric street car may presume that one driving a carriage in front of his approaching car, and who he sees is about to turn upon the track in front of his car, will desist from so doing when he sounds the gong of his car; and he is only bound, as an ordinarily careful man, to exert efforts to stop his car after he sees that his warning is unheeded.

4. A driver of a buggy, whose ears are muffled in a seal-skin cap and coat, is guilty of contributory negligence in driving on an electric street car track without looking any considerable distance up or down the track to see if a car is approaching, since in such case she is deprived of a warning through the sense of hearing.—(Cawley vs. La Crosse City Ry. Co., 82 N. W. Rep., 197.)

A Large Convertible Car

The engravings which accompany this article show two views of a double-truck, twelve-bench, convertible car recently built for the New Castle Traction Company, of New Castle, Pa. This car is one of a lot supplied this company by the J. G. Brill Company, and is the largest of the kind yet turned out. The idea of the convertible car is one which is receiving much attention from street railway men at the present time. The public are everywhere, even in our northern cities, clamoring for an open car during the warmer weather. They are equally clamorous to have these cars taken off whenever a cold wave interrupts the pleasant weather, and they object, very rightly, to the use of them during chilly weather late in the fall or early in the spring, yet throughout the year, even in winter, there are days when the use of such cars materially increases the traffic of a street railway. Boards of Health in some cities where open cars are extensively used have found it necessary to interfere and demand that a certain proportion of closed cars be run the whole year round. The railway manager at the present time is confronted with the problem of a double equipment, half of which only can be used at any one time. This, of course, means double storage capacity, with all the attendant expenses, and it also means, if the public are to be thoroughly accommodated, the storage shall be arranged in such a manner as to make it possible to change from one to the other kind of car at the shortest possible notice. Actual practice succeeds only in using a double equipment, and keeping the open car in service as long as possible. It is put on weeks before the proper time in the spring in order to take advantage of any stray warm days which might occur, and it is often kept on in the fall a month longer than is comfortable for many of the traveling public.

The aim in designing the Brill convertible car was to have a single equipment which could at all times give the railway manager the car he mosts needs at the required time. Furthermore, it provides a car which is entirely self-contained, and is at all times ready to be changed from one type to another without going to the shops or car houses, and without further labor than that which can be given by the motorman and conductor in a few minutes. With an equipment of this character the storage capacity of the car houses is reduced practically one-half; there is a corresponding diminution in the sizes of buildings, the quantity of land required, attendance necessary and capital invested.

How perfectly the Brill car has answered the requirements can be judged from the engravings and from the accompanying description. Fig. 1 shows the car open for summer use. It is in all respects a standard cross seat, center aisle open car. From a layman's point of view it is identical with the usual type. The expert notices, perhaps, the panels in the corner and certain minor details of construction, as for example the form of grab handles and positions of the panels. Fig. 2 shows the car closed, the steps folded up ready for winter use. It is practically a standard box car on double trucks. It is true there is a folding step and grab handles at each window post, but the arrangement of the windows and panels is similar to that of the ordinary car. With the exception of the fact that the windows rise instead of drop, the car is, as far as the passengers are concerned, the same in operation and arrangement as a closed car. The curtains operate in the same way—when closed they come to the window rail; when open they come all the way to the floor. These New Castle cars have twenty-four benches and seat forty-six persons, one of the stationary seats at each end of the car accommodating one person only. The open car has the Brill round-corner seat end panels, which give great ease of entrance from the sides.

The cross-seat car is being looked upon with more and more favor by street railway men, and several large companies are ordering them extensively. The idea is that there is a profit in carrying seated passengers, and that when seated people are more comfortable if they face in the direction in which they are moving.

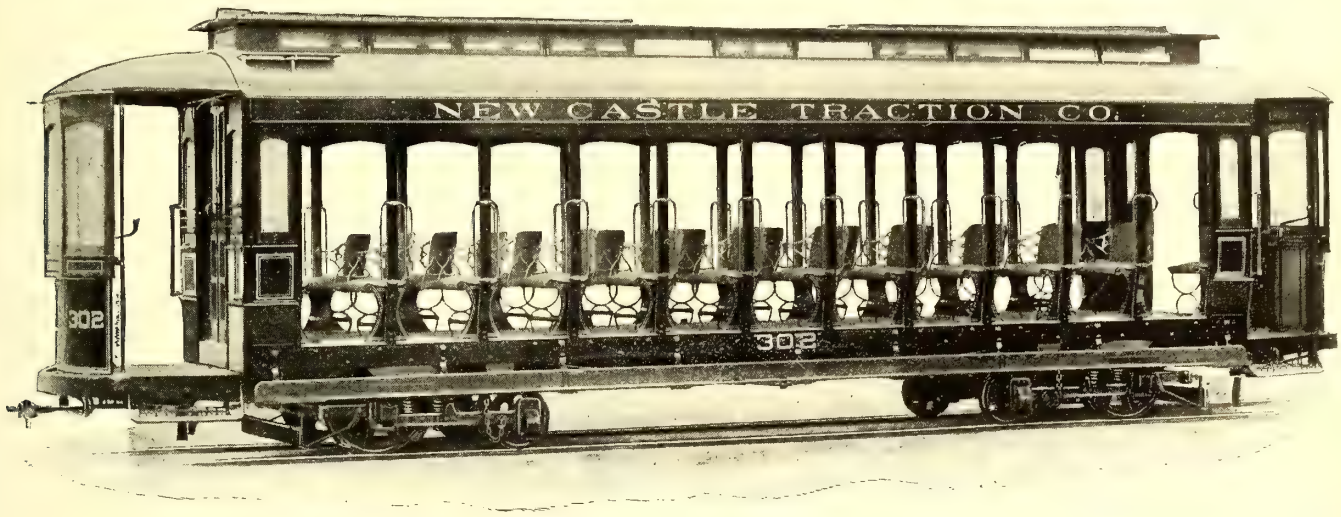


FIG. 1—CONVERTIBLE CAR FOR NEW CASTLE, OPEN

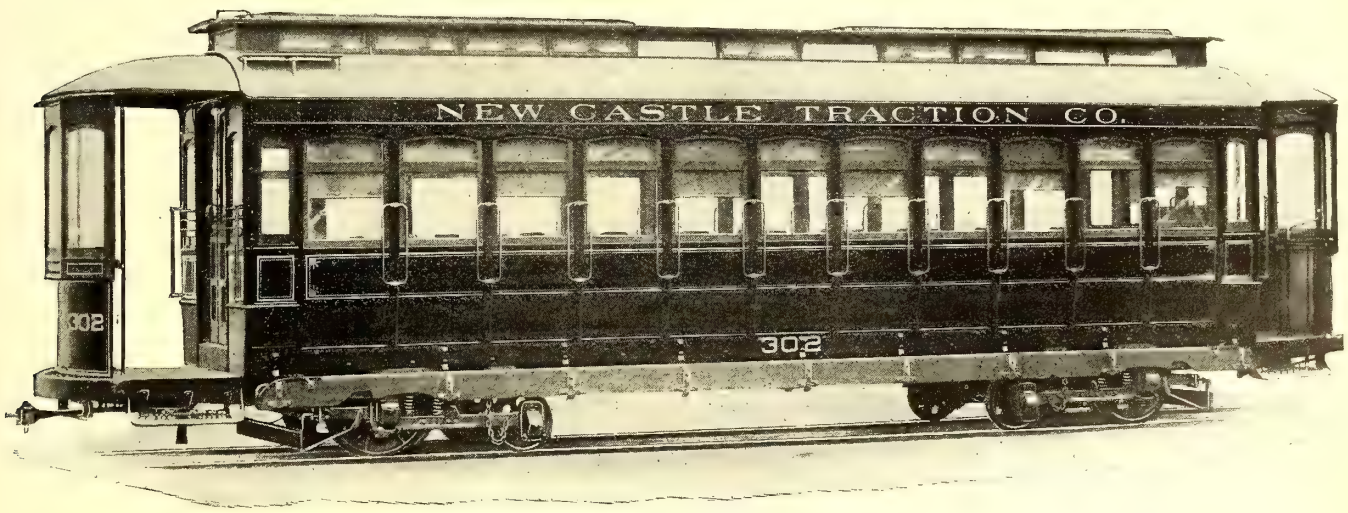

FIG. 2—CONVERTIBLE CAR FOR NEW CASTLE, CLOSED

The following are the principal dimensions and details of these cars: The length over end panels, 30 ft. 8 ins.; length of platform, 4 ft.; length over dasher, 38 ft. 8 ins.; width at the sills, 6 ft. 8¾ ins.; width over the posts, 7 ft. 5½ ins. The extreme width of the car when the steps are down is 8 ft. 8 ins.; when they are up the extreme width is 7 ft. 8 ins. The height of the platform steps is 14 ins. from the head of the rail; the riser is 13 ins. The long step or running-board is 19 ins. from the track and 15 ½ ins. from the step to the floor of the car. The width of the car inside at the center is 8 ft. 2½ ins., and the body is 9 ft. 3½ ins. from the bottom of the sill over the trolley board. These cars were mounted on maximum traction trucks, with driving wheels 33 ins. in diameter, 2-in. tread and ⅝-in. flange. They were fitted with electric brakes, Brill angle-iron buffers, Brill portable vestibules, radial draw-bars, two sand-boxes, two Dedenda gongs. The General Electric Company furnished cables, controllers and resistances. The side panels are of the new type, having metal on both sides of the slats, making a very warm car side, and, being flexible, they fill the groove completely. The interior of the car is so nearly identical with those ordinarily used that even an experienced railroad man would not be likely to note the fact that there was anything unusual in the construction. The center of the car, perhaps, appears a little more lofty than usual. The ventilators and monitor deck are the same. The construction of the roof is such as to give this car an unusual amount of stiffness and strength. The letter board and panels are made from a single piece, and are halved upon the posts and carlines. The necessary interior furring strips also anchor each of the carlines, while the carlines being wider than usual at the foot and made up as part of the posts are much stronger than those of any ordinary car. Although this design has been in use long enough to have made its weak points visible, no faults of any consequence have appeared. Cars of this type have been in a number of accidents which have demonstrated their unusual strength.

Electric Freight Locomotive at Whitinsville, Mass.

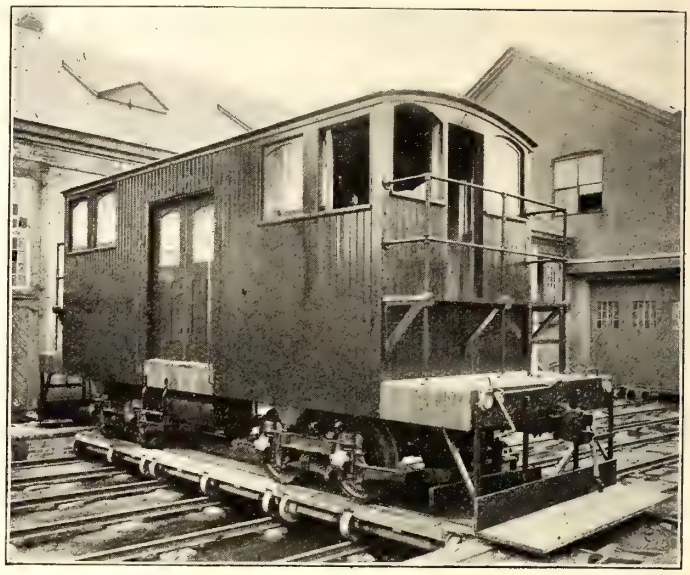
The use of electric locomotives is increasing, not only for passenger but also for freight transportation. Several recent electric freight locomotives have been described in these pages, and views of a recent machine of this class, built by the Taunton Locomotive Manufacturing Company for the Whitin Machine Works, of Whitinsville, Mass., are given herewith.

The main frame of the locomotive body consists of two end

INTERIOR OF CAB

sills of 8-in. x 12-in. oak, eight longitudinal sills of 4⅝-in. x 11-in. yellow pine, and two bolsters of 8-in. x 11-in. yellow pine. On this frame is laid a flooring of 1¾-in. spruce. The cab, which is built on this frame, is constructed of four corner posts of 6-in. x 6-in. yellow pine, and belt rails, door framing and side braces of 2¾-in. x 4-in. yellow pine. The end roof carline is of 2½-in. x 3-in. white pine curved, and the other roof carlines are 1¼-in. x 9½-in. yellow pine. The outside roofing and sheathing is of ⅞-in. North Carolina pine, and the inside roofing and sheathing is of ⅞-in. North Carolina pine, except for about 4 ft. at each end, where the roof carlines were made circular on the under side, as well as the top, so as to allow the platform to be placed as high as possible, and the sheathing was reduced to ⅜ in.

The locomotive is mounted on Peckham No. 14 B-3 double trucks, fitted with 33-in. wheels on 4½-in. axles. The electrical equipment consists of four G. E. 57 railway motors, whose armatures are wound for slow speed, each coil containing six turns. Series parallel controllers allow the operation of the locomotive at a speed of 5 to 6 miles per hour on the series slow running point, and 9 to 12 miles per hour on the multiple point. The



GENERAL VIEW OF LOCOMOTIVE

six-panel resistances are under the cab platforms, with the idea of utilizing their heat in the winter time to warm the cab.

The automatic air-brake apparatus with which the locomotive is equipped was supplied by the Christensen Engineering Company, and will operate in connection with any of the standard automatic brakes. The locomotive is accordingly supplied with coupling hose in order that the air brakes may be used on any freight car which it has to handle.

The motor compressor is situated underneath the engineer's platform at one end of the car, and has a capacity of compressing 20 cu. ft. of free air per minute to 100 lbs. pressure. The main storage reservoir is placed beneath the car, as are the brake cylinder and the auxiliary reservoir, and is connected by piping to the compressor and to the engineer's valves at the ends of the locomotive. The auxiliary reservoir is piped to the triple valve on the tail of the brake cylinder, which is in turn connected to the engineer's valves. The locomotive is supplied with whistles, one at each end, which are blown by compressed air.

Reduced Tariff on Electrical Machinery in Italy

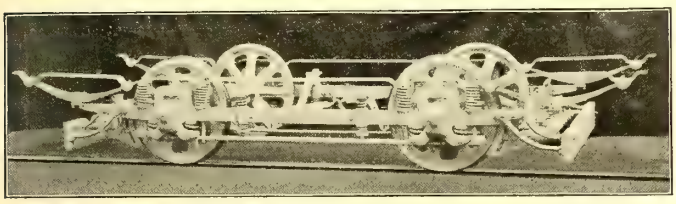
The United States State Department has made public the text of the new reciprocity treaty with the Kingdom of Italy. In consideration of reductions in the United States tariff upon certain Italian products, chiefly wines, the Italian government proposes to lower its duties on some six or seven articles of American manufacture, among them scientific apparatus, dynamo-electric machinery and varnish. Under the agreement the Italian import duties on these manufactures will not exceed the following figures:

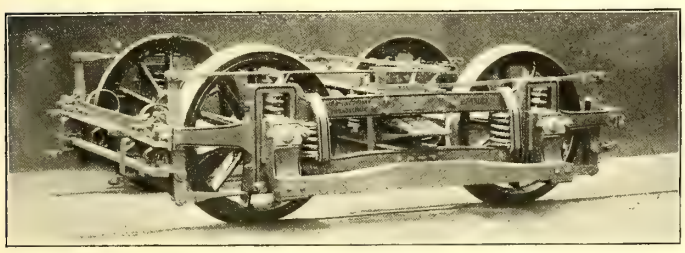
Articles	Rate in Lire Per Quintal
Scientific instruments:	
(a) Of copper, bronze, brass, or steel.	
(1) With spy-glasses or microscopes, or graduated scales or circles, spy-glasses for use on land, monocles, binocles, lenses, detached and mounted	30.00
(2) Not provided with any optical instrument nor with graduated scales or circles	30.00
(b) Of all kinds, in the construction of which iron is evidently predominant	30.00
Upon dynamo-electrical machines:	
Upon varnishes, not containing spirits nor mineral oils	20.00
(1) The weight of which exceeds 1000 kg	16.00
(2) Weighing 1000 kg or less	25.00
Upon detached parts of dynamo-electrical machines	25.00

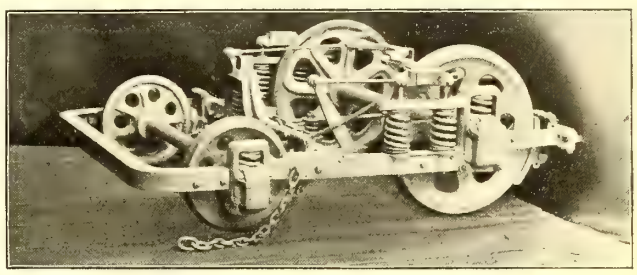
The treaty, which must first be approved by the Italian Parliament, will continue in force until the expiration of the year 1903, and if not denounced by either party one year in advance of the expiration of said term, it will continue in force until one year from the time when one of the high contracting parties shall have given notice to the other of its intention to arrest the operation thereof.

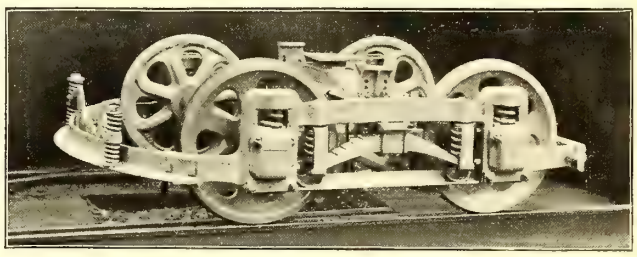
The Brill Exhibit at the Paris Exposition

Reference was made in the last issue to the exhibit at the Paris Exposition of the J. G. Brill Company. The principal objects shown are illustrated herewith. As with most of the transportation exhibits, part of the apparatus shown is in the Champs de Mars section and part in the Transportation Building at Vincennes.









BRILL CARS AND TRUCKS AT THE PARIS EXPOSITION

The exhibit in the former comprises four quarter size truck models showing respectively: A model of the 27-G, of the 21-E, of the Maximum Traction and No. 27 trucks. The chief exhibit of the Brill Company, however, is at the Vincennes annex. The most conspicuous objects here are the snow sweeper, illustrated in July, and a Brill convertible car complete, mounted on a 21-E truck. This convertible car, which is illustrated herewith, was constructed to meet the requirements and restrictions imposed by French government officials relating to tramway rolling stock.

There is also shown one 27-G bogie truck, similar to other trucks of this same type which the company has furnished for use on French tramways; also one maximum traction truck of the same construction, as are now being furnished for use under French cars.

The maximum traction truck exhibited is fitted with solid forged wrought iron side-bars, this being one of the latest improvements in double-truck construction. The 21-E truck is also fitted with these solid forged iron side-bars, according to the Brill practice for several years past. The company also exhibits here one of its No. 27 high-speed trucks.

To show the other patterns of cars manufactured by it the Brill Company has out a large stand containing quite a number of miscellaneous photographs of cars and trucks, the stand being arranged for easy access in order that the public may examine the different types of rolling stock which the company has recently furnished throughout the world. The whole exhibit, which is one of the largest of the American exhibits at the Paris Exposition, covers a space 100 ft. x 10 ft.

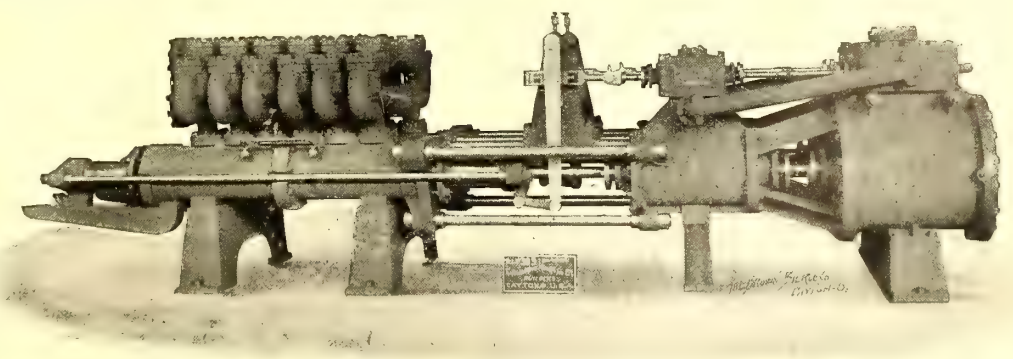
As this issue goes to press a cable dispatch states that the Brill Company was awarded, by the official jury, two grand prizes, one for its system of trucks, the other for its convertible cars. These are said to have been the only grand prizes awarded for electric trucks or convertible cars.

A New Design for a Compound Duplex Pressure Pump

The accompanying illustration shows a new compound duplex pressure pump to develop a maximum pressure of 700 lbs. per sq. in. manufactured by the Stilwell-Bierce & Smith-Vaile Company, of Dayton, Ohio.

The liquid end is of the end-packed trombone style. The cylinders are made of special metal; mounted thereupon are separate chambers for the location of the valves. The chambers are also constructed of special metal and designed with a view of facilitating quick access for the inspection of the valves.

The valves are of the hydraulic pattern, made of steel, and guided from below. An extension piece is provided for supporting the water plunger, and an approved adjustment device provided therefor.

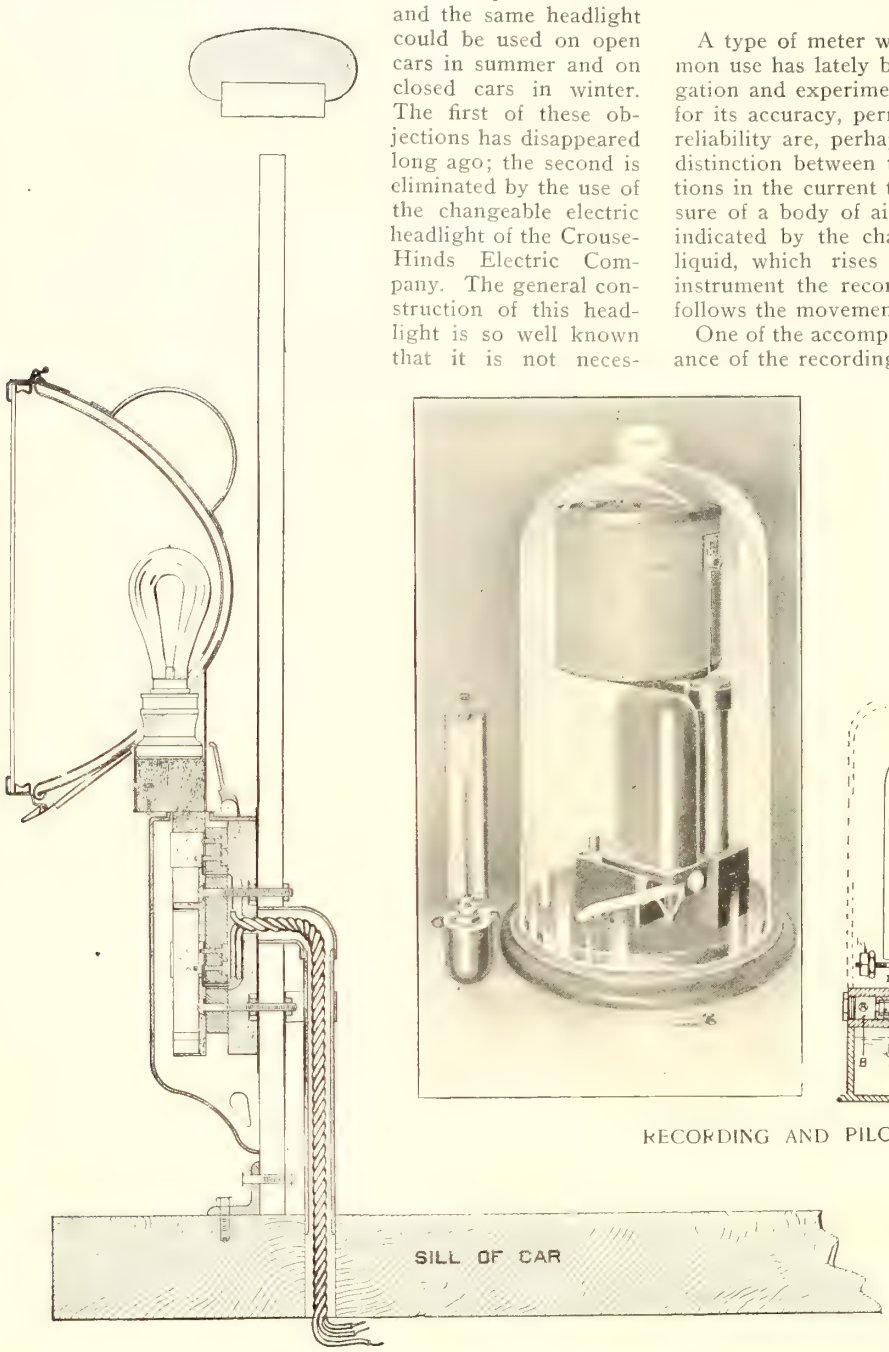


COMPOUND DUPLEX PRESSURE PUMP

The water end is mounted on heavy supporting columns. An engine of the transposed cylinder type is furnished, giving free access to all steam pistons without dismantling the pump. The outside valve adjustment is a feature of this design.

Changeable Electric Headlight

When electric cars were first introduced, electric lamps were, of course, used for the interior illumination of the car, but oil was employed exclusively for headlight purposes. The reason for this was probably two-fold; one was that the electric light was not considered reliable enough for headlight service, where the safety of the passengers, as well as that of persons crossing the track, is dependent to such a great extent upon the burning of the headlight at all times; the other reason was undoubtedly the fact that the oil headlight could be changed from one end of the car to the other so that a double equipment was not necessary for each car and the same headlight could be used on open cars in summer and on closed cars in winter. The first of these objections has disappeared long ago; the second is eliminated by the use of the changeable electric headlight of the Crouse-Hinds Electric Company. The general construction of this headlight is so well known that it is not necessary to discuss it here. The company has made a few changes in detail, however, during the last year, which have increased the convenience and reliability of the device. A section of the headlight, showing the construction of the receptacle as now built, is shown herewith. The receptacle, of course, is attached to each dasher, and the contacts form part of the light circuit of the car. One headlight only is required for each car in operation, and by placing this light in one of the receptacles, the lamp is automatically thrown into circuit, cutting out the lamp over the front platform. When the headlight is changed to the other platform the lamp cut out is thrown into circuit again, and the other platform light is cut out.



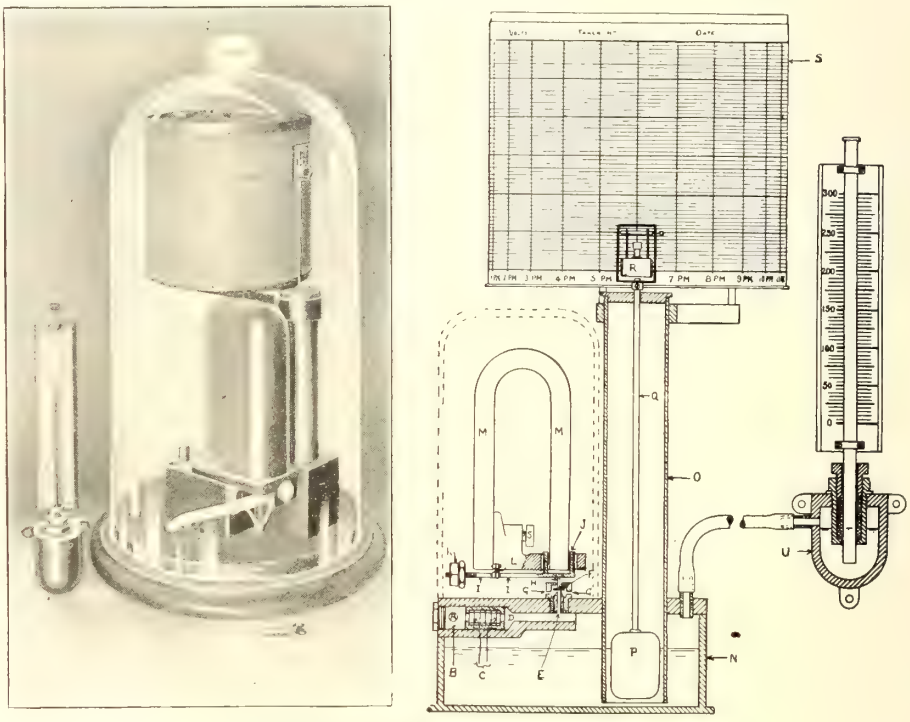
SECTION SHOWING HEADLIGHT AND RECEPTACLE

The contact stem of the headlight is made of second-growth hickory, kiln-dried and boiled in paraffin to make it thoroughly waterproof; the receptacles, which are mounted at each end of the car, are made with a kiln-dried oak back, having mounted thereon a ½-in. slate block. The brass connections of the receptacles are mounted on this base, and the contact springs are made of phosphor bronze. The receptacle is encased in a cast-iron backing 10 ins. high x 4 ins. wide. The wires are carried through the dasher in a small iron pipe. The opening of the receptacle not in use is protected by a cast-iron lid, which drops in place when the headlight is removed, making it water-tight.

A New Recording Meter

A type of meter which differs greatly from those now in common use has lately been brought out. Much painstaking investigation and experiment have been expended on it, and the claims for its accuracy, permanence, compactness, legibility and general reliability are, perhaps, not too strongly expressed. The radical distinction between this and the ordinary type is that the variations in the current to be measured control the variation in pressure of a body of air in a closed vessel. This latter variation is indicated by the change in height of a column of non-volatile liquid, which rises and falls in a tube. In the recording instrument the record is traced by a float-supported pen which follows the movements of the liquid's surface.

One of the accompanying illustrations shows the general appearance of the recording meter, and a small "pilot" indicator, which



RECORDING AND PILOT INSTRUMENT

can be placed in any desired position. The other illustration gives a section of the apparatus showing its operation. Air is supplied either from a small air pump furnished with the instrument, or from some other source, at a pressure of about 1¾ lbs. per square inch to the orifice, *A*, in the chamber, *B*. The air then flows through a series of porous diaphragms made of filter paper, whose prime function is to serve as an air resistance, but incidentally remove any dust particles and serve to make the instrument dead beat, and then enters the passage, *D*, into which is drilled the opening, *E*, which is capped by the valve, *F*. The valve itself consists simply of a small flat disc of non-oxidizable metal, *F*, resting on a circular seat with escape ports, *G*, below it, and a pin, *H*, resting on top. On the pin rests a spool, *J*, carried by one end of the lever, *I*, on the other end of which is a counter-weight, *K*, by means of which the effective weight on the pin, *H*, can be adjusted. The spool is wound with wire through which the current to be measured is passed, this being done by means of the two short thin copper ligaments, *L*, which support and form the fulcrum about which the lever can oscillate. A magnet, *M*, furnishes a field of force such that the reaction between it and the current forces the

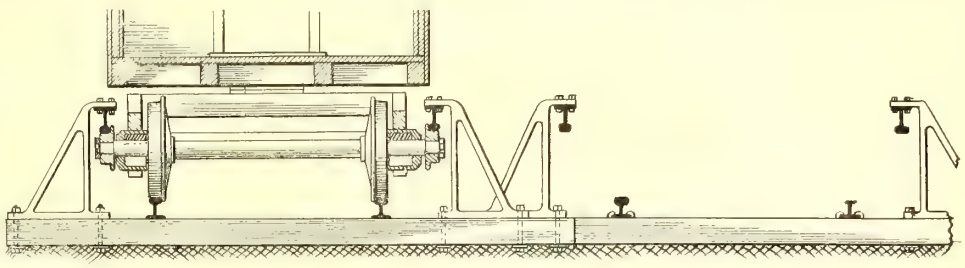
spool down with a force increasing as the current increases. The valve, *F*, is thus a variably loaded safety-valve, whose blowing-off point is constantly and proportionately varied by the current variation. The counter-weight, *K*, on the lever is so adjusted that when no current is passing through the spool the weight on the valve-pin is such that the blowing-off pressure in *D* is one sufficient to force the liquid in the closed chamber to such a height that the pin will register zero and the liquid in *U* will be forced to the zero position on the scale. The pressure cannot go above this when no current is on, as any tendency to increase simply results in lifting the valve slightly higher, whereupon more air escapes and the pressure falls back; nor can it go lower, as if there were this tendency the valve would partially close because of the spool weight, and the less rapid escape of air through it would cause the pressure to build up again because of the constant flow of air from the high-pressure supply at *A* through the air resistance, *C*. It is thus seen that the air pump must not necessarily keep a constant pressure on the opening, *A*. Exactly the same thing holds good when the weight on the valve is that due to the non-counterbalanced portion of the spool weight plus the downward thrust caused by a given current through it. This gives what is practically a heavier loaded safety-valve, so that the blowing-off pressure in *N* is higher, and this higher pressure, of course, forces the liquid up further, thus showing the presence of a current. The height to which the liquid rises is directly a measure of that current, because the extra downward thrust on the spool is, from the magnetic field and spool design, proportionate to the current.

It should be noted that the only work that the varying current has to perform is to *control* the air pressure, the actual energy required to move the liquid, and so show the variation, being supplied by an independent source, whose power is, comparatively speaking, unlimited.

The "column" instruments, described above, are being manufactured by the Whitney Electrical Instrument Company, and introduced by Machado & Roller, of 203 Broadway, New York City. A plain indicating instrument having a vertical scale like the pilot indicator, but extending 18 ins. between the zero and maximum readings, as well as a type of meters to be used on alternating currents, are also constructed.

A Device to Prevent Derailment

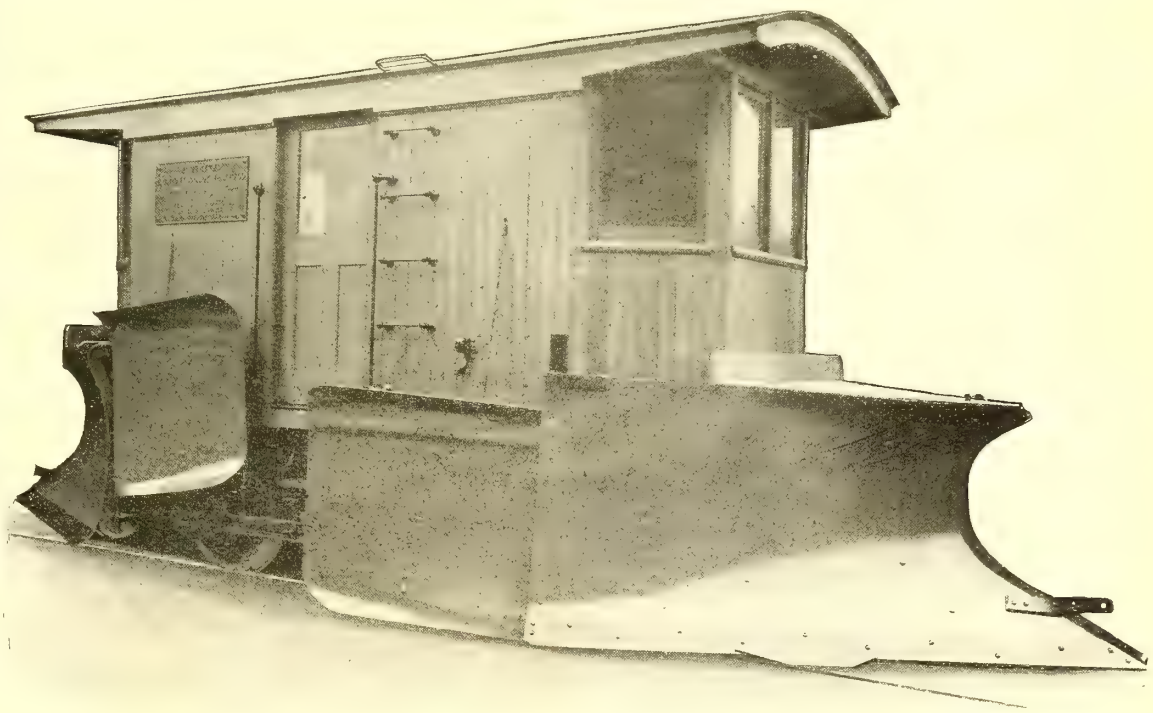
The accompanying illustration gives a good idea of a new system of track construction whereby it is claimed high speeds may be obtained without fear of derailing the cars. As seen from the figure, there is no material variation from the standard roadbed and rolling stock of the present day. The only difference in the roadbed is that for about every fourth tie one somewhat longer is substituted, on which to fasten the brackets for the support of the safety rails. These consist of ordinary T-rails turned upside down and bolted securely to the brackets, thus, if anything, increasing the stiffness of the roadbed. The car axles, instead of terminating in the grease-box, are extended until they project out under the inverted safety rails, and are provided with a small anti-friction roller at their extremities, which travels along those rails. By having this roller insulated from the axle and using a contact shoe on each side of the car, the safety rails may be insulated and used as the two sides of a trolley circuit, and the cars run electrically. This would be, of course, the probable form of power for high-speed service. The inventor of the system is W. T. Van Dorn, of Chicago, manufacturer of the Van Dorn automatic car coupler.



DEVICE FOR PREVENTING DERAILMENT

A Powerful Snow Plow

The new 1901 snow plow of the Taunton Locomotive Manufacturing Company differs in a number of particulars from the company's 1900 model. It weighs 5 tons without motors, and is thus somewhat lighter than the Taunton standard plow of last year. This reduction in weight has been secured entirely by dispensing with cast iron, especially in the shape of the two heavy counterbalance weights. The manufacturers have also substituted wrought iron and timbering for a large amount of cast iron used in last year's plow, and the noses are now raised and lowered by a chain, operated by worm and gear mechanism. The whole weight of the nose rests on the rail, although the height of the nose can be adjusted to suit any condition. This renders the plow especially valuable in light snows, and guarantees a clean rail under these circumstances. At the same time the shape of the nose and heavy oaken backing give sufficient strength for heavy drift work.



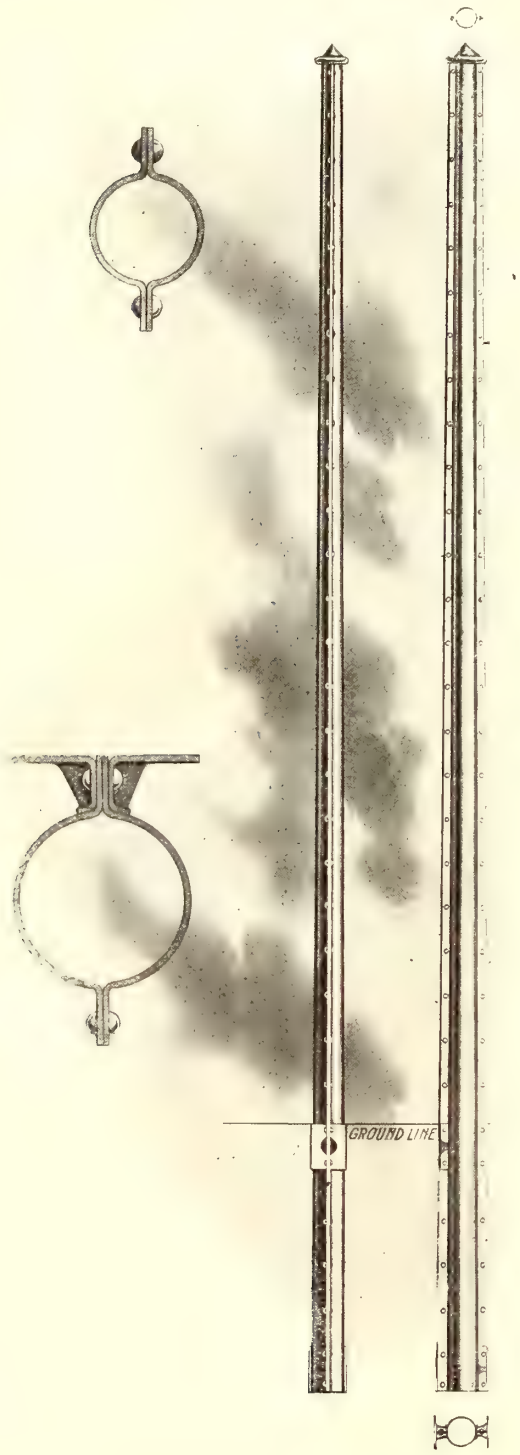
A POWERFUL SNOW PLOW

The wings are also a departure from former Taunton practice, and are believed to be an improvement, inasmuch as they dispense with the wing hinge pin, always difficult to keep in shape, when the plow is sent against frozen ground or hummocks of ice. The nose is carried so far back on each side that the wheels are thoroughly protected, and the sides of the plow are also protected from snow without in the least interfering with accessibility to the running gear. The hood or overhang part of the roof has been practically taken away to make perfectly easy the manipulation of the trolley rope. The effective Taunton digger is applied to this plow, and, as now built, the manufacturers, who have had many years of experience in electric plow building, state that they can see no opportunity for further improvement in a plow for all-round single track work. The changes made this year, as stated, are not in design, but are mainly in the substitution of timber and

wrought iron in place of cast iron. For ordinary work the excessive weight is not often necessary. For the heaviest kind of drift work, such as is met in Maine and Canada, however, the company makes the Taunton heavy-nose plow, which weighs twice as much as the plow described above.

A New Steel Trolley Pole

A trolley pole which differs in many important respects from the ordinary ones now on the market has recently been brought

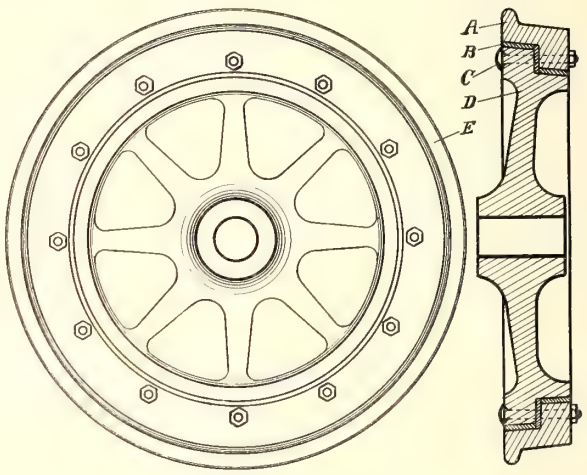


SECTIONAL TROLLEY POLE

out by the Pressed Steel Car Company, of Pittsburgh, Pa. The accompanying engraving presents a good idea of the general appearance of the pressed steel poles, sectional views being given to aid the reader's understanding of its construction. The new style is made in two semicircular sections, so firmly riveted together that they become practically one piece. Thus a maximum standard of strength is established throughout its entire length, and the occasional uncertainty which accompanies the use of poles having two or more longitudinal sections is eliminated. Brackets of a form shown in the illustration are placed on the flanges of the pole at the ground line and at the base, which give additional rigidity. The manufacturers claim that a pole of this kind can be made more cheaply than a tubular pole, and have prepared dies which enable them to turn out any size from 24 ft. to 40 ft. A malleable or cast-iron cap covers the top of the pole, which gives an artistic finish to its handsome appearance.

A Noiseless Car Wheel

The introduction of 2 or 3 lbs. of paper beneath the tire of a car has been tried with marked success in Chicago. Four wheels made in the manner shown in the accompanying sketch have been in operation for some time on a street car, and a similar equipment is being tried by one of the steam roads. This new style of



NOISELESS CAR WHEEL

wheel is the invention of I. Hogeland, of Chicago, who claims that by its use a sufficient recoil or cushion is obtained to render steel tires unnecessary, even for heavy steam railroad practice. The wheels were made by the Wells & French Car & Wheel Company. The tests are being made under the severest conditions, the street car on which the wheels have been placed running over some of the worst track in Chicago, so that the satisfactory operation of the invention under less trying circumstances is assured.

New Method of Hardening Steel

The Bethlehem Steel Company has recently perfected a new method of hardening steel, which is particularly adapted to tool steel. This process, which is called the Taylor-White process, has been employed in the Bethlehem works with remarkable results, and has enabled the company to speed up its main lines of shaft from 90 to 250 r. p. m. and greatly to increase the output of its machine shops.

One virtue of the Taylor-White process is that it gives to the steel the very valuable and exceptional property of retaining a high degree of hardness when heated to a visible red heat. It is possible with one of these tools to cut steel at a speed so great as to heat up the point of the tool to redness and have it continue to cut for several minutes at this speed, leaving an unusually smooth finish on the work, as well as cutting accurately to size. The advantage in leaving a smooth roughing cut and of having the work accurately to size will be readily appreciated, as it materially lessens the work of finishing. The practical speeds at which these tools will run has been found to be from two to four times that of any steel with which the company has experimented, and it has endeavored to obtain the best in the market. The effect of the Taylor-White process, which is applied after the tool has been dressed or machined to shape, penetrates to the center of the steel, even in the largest tools ever treated, i. e., 4 ins. square.

All of the standard brands of self-hardening steel which have been experimented with are improved to a more or less extent by the treatment; it is preferred, however, to use a steel of special composition in order to get the greatest uniformity and maximum results. This special steel forges so much more readily than the general run of self-hardening steels that tools of difficult shapes may easily be made up.

The company has also discovered a simple and comparatively rapid method of annealing this special steel by which tools may

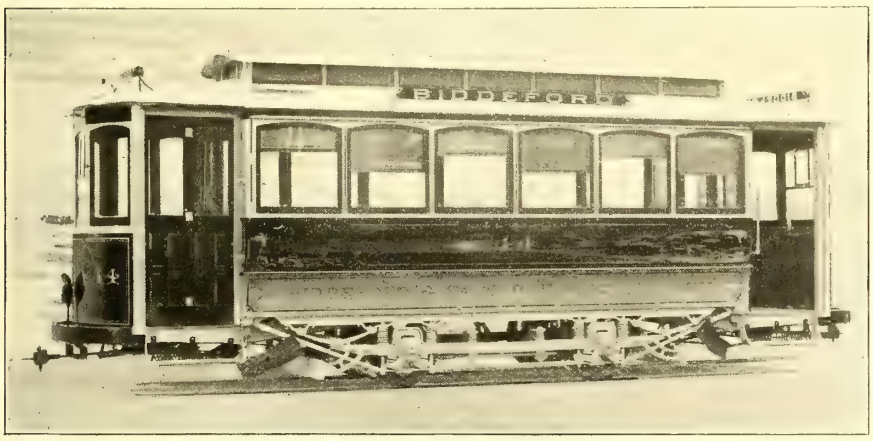
be easily machined to shape, making it applicable to twist drills, chasers, inserted cutters, etc., which have heretofore not been made from self-hardening steel.

A very important feature resulting from the use of this process is that the tools are extremely uniform in quality, so that work on which they are used can be regularly performed at the maximum rate of speed. The variation in the quality of these tools does not run over 5 per cent, which insures a much greater degree of uniformity than is attained in any other tools that we know of, whether made either of tempered or any air-hardening steel. With uniform tools the piece-work system can be most efficiently used, as the piece rate must always be based not on the average cutting speed of the tools, but on the speed of the worst tool in use.

The company proposes to sell shop rights to use this process, the price to be based upon the number of tools in use, as well as their size and character.

Car for Cold Climate

The type of car shown in the accompanying engraving is one which has been found useful and satisfactory for suburban lines



CLOSED CAR FOR BIDDEFORD

in very cold and trying climates. The car in question was built by the J. G. Brill Company for the Portland Railroad Company to be operated on the Biddeford & Saco line. The body is 18 ft. long and is mounted on No. 21-E trucks, furnished with two motors. The platforms are 4 ft. 6 ins. long with so-called circular ends. They are completely enclosed, having folding doors which turn back against the body of the car. This gives complete protection to both motorman and conductor, a feature highly necessary in a climate where the thermometer often drops below zero and where high, piercing winds are the rule during the winter. The cars measure 27 ft. over all and are 6 ft. 2 ins. at the sills and 7 ft. 6 ins. over all. Looking at the engraving it will be noticed that scrapers are fitted at each end of the car. These attachments are almost equivalent to a snow plow, and enable the car to run through light snow and even move the small but annoying drifts which are common on some parts of the line. Scrapers could be more frequently used to advantage, as they prevent many delays in winter operation, which are both annoying and costly. The ends of the car are fitted with Brill angle-iron bumpers, sand-boxes, Dedenda gongs and electric headlights. The track is standard gage, 4 ft. 8½ ins. The wheel base is 7 ft., thus securing great steadiness of motion and enabling a high speed to be maintained with comfort. The car measures 12 ft. from the head of the rail over the trolley board.

The finish over the windows inside is of mahogany, the sashes are of mahogany with arched tops, and the head lining is of three-ply quartered oak. Four-sided reversible signs are placed on the sides and ends of the car. The trim throughout is solid bronze. The total weight of the car without motors is 11,800 lbs. The seats are longitudinal, with spring seats and backs covered with crimson plush. Cars of this general type are easily heated and the practice is fairly divided between electric heaters and stoves.

Nelson C. Draper has been appointed superintendent of the Peoria & Pekin Terminal Railway Company, of Peoria, Ill., to succeed Mark H. Hubbell, resigned. Mr. Draper has been connected with this road for some time as electrical engineer, and was formerly connected with the Central Railway Company, of Peoria.

A New Incorporation

Messrs. Fowler and Robert, comprising the firm of Fowler & Robert, the organization of which was announced in the STREET RAILWAY JOURNAL a few months ago, have found their business as manufacturers and dealers in general railway supplies has increased so rapidly as to call for a large extension of their facilities. For this reason, they have organized a company, which will be known as the Fowler & Robert Manufacturing Company, have secured good-sized works at 1263 Atlantic Avenue, Brooklyn, and have enlarged their field and personnel. The latter is now extremely strong, and includes not only Messrs. Fowler and Robert, who are well known in the street railway field, but also George W. Linch, for a long time superintendent of the Dry Dock, East Broadway & Battery Railway Company, in New York City, and Fred Vieweg, as well as others. The company is prepared to supply all the specialties formerly made by the Lewis & Fowler Manufacturing Company and the Brooklyn Railway Supply Company, and will make a specialty of the L. & F. improved fare register. This register, which is the former Lewis & Fowler, but in which have been embodied a number of important improvements, has stood the test of service for twenty years, and is one of the earliest and best known in the field. The new company believes that now that these registers will be manufactured and supplied by the same persons who were instrumental in its original design and manufacture, and now that repair parts for it can easily be secured, the machine will be received with all its former popularity. In addition, the company will manufacture repair parts for L. & F. electric snow sweepers and car heaters, and will manufacture, or has secured the agencies for, all kinds of car trimmings, bells, gongs, brake-shoes, bearings, special track work, trolley wheels and harps, commutators, canopy switches, etc., as well as the Thistle brand of metallic paints. The New York office remains at 149 Broadway.

New Publications

Horseless Vehicles, Automobiles and Motor Cycles. By Gardner D. Hiscox. Published by Norman W. Henley & Company, New York City. 459 pages. Illustrated. Price, $3.

In this book the author again exhibits his faculty of practical discrimination. From the immense field offered by the present state of automobile manufacture he has made most happy selections, and compiled a series of illustrated descriptions of steam, internal combustion, compressed air and electrical vehicles, which cannot fail to prove of service to those interested either in their production or operation. As is natural in books of this kind, unlimited use has been made of patent drawings, illustrations from trade catalogues, etc., but as they admirably serve their intended purpose no fault can be found with their introduction. The first two chapters contain many interesting facts concerning the utility and history, and considerable space is given to the running, care and repair of automobiles, but the greater part of the volume is devoted to the various styles which the author has chosen to describe.

Gas-Engine Construction. By Henry V. A. Parsell, Jr., and Arthur J. Weed. Published by Norman W. Henley & Company, New York City. 296 pages. Illustrated. Price, $2.50.

The amateur mechanic who is interested in gas engines will find much information in this volume. After thirty-eight pages of rather meager description of the various types and some commercial forms, the author devotes nearly the entire remainder of the book to the manufacture of a ½-hp engine. Starting at the patterns, instructions are given in great detail for every operation until the work is completed. The book is uniquely illustrated by reproductions of photographs taken during the actual construction of such an engine by the author, as well as the ordinary working drawings. A feature which will, perhaps, make the book of interest to engineers is an annotated list of gas-engine books and periodicals published in the English language, with which it closes.

Corporations and Public Welfare. Published by McClure, Phillips & Company, New York. 208 pages. Price, $1.50.

This book contains a collection of addresses delivered at the annual meeting of the American Academy of Political and Social Science in Philadelphia in April. The volume contains many papers of interest to students of sociology, and the subject of municipal control receives quite a little attention.

CURRENT NEWS

Third Rail Attacked in Brooklyn

The Department of Public Buildings, Lighting and Supplies has begun an attack on the Brooklyn Rapid Transit Company, and has officially notified the company that it must either make the system absolutely safe or do away with it altogether on the elevated lines. This action is said to have been prompted, as officially put, "Because of the numerous serious accidents on the system since its installation," but is believed to be a similar political demonstration to that made against the Manhattan Company by Tammany Hall late last year.

Proposition for a Sub-Sidewalk Railway in Chicago

J. H. Farrar, of Chicago, has submitted plans and detailed explanations of a sub-sidewalk railway to the Street Railway Commission. The chief merits of the system are in the cost of construction and the high speed which may be attained. The scheme provides for the construction of the road directly under the sidewalk.

For use on the sub-sidewalk railway the inventor proposes an open car, resembling a carette with the top cut away. The sidewalk above furnishes the top for the car and prismatic walks above give light, aided by electric lights within. Heat is to be furnished from gas radiators along the curb.

Wire-Tapper Caught in Milwaukee

On Aug. 25 the engineer of two large Milwaukee buildings was arrested on the charge of stealing electricity from the Milwaukee Electric Railway & Light Company. Secret connections were made with the lighting lines of the company, and power was stolen for lighting both buildings. Superintendent Rau, of the Milwaukee Company, had his suspicions aroused, it is said, by the unusual hours at which lights were lighted in the building, and at once began an investigation, feeling certain that the plants in the building were not being operated at the unusual hours at which the lights were used. It is said that the case will be prosecuted to the bitter end and that an example will be made of the thief.

Reorganization in Elmira

A meeting was held last week of the Elmira Water, Light & Railroad Company, the new company in Elmira, at which officers were elected, and the company took over the property of the old Elmira Municipal Improvement Company. The latter has, for some time past, been in the hands of a reorganization committee, consisting of George W. Young, chairman; Walter G. Oakman, James C. Simpson and E. C. Jones. The new company owns and operates the water, gas and electric light properties in Elmira, as well as the former street railway property of the Municipal Improvement Company. The board of directors of the new company consists of Frank R. Ford, of New York, president; Charles F. Uebelacker, vice-president and general manager; John Alvin Young, H. M. Francis and Frank H. Davis. J. M. Diven is secretary and treasurer, and H. D. Benner is assistant secretary.

From Schenectady to Albany

The United Traction Company, of Albany, N. Y., and the Schnectady Railway Company have come to an understanding regarding the construction of an electric railway from Schenectady to Albany, and a company has just been incorporated to carry out the project. The company is known as the Albany & Schenectady Traction Company, and is capitalized at $100,000. The road will be built over the Schenectady turnpike. The company has been granted the right to operate over the lines of the United Traction Company to the heart of Albany. Following are the officers and directors of the company: Jesse H. Leonard, president; J. S. Klingelsmith, vice-president and general manager; C. D. Miller, secretary; Edward P. Williams, treasurer. Directors: Jesse H. Leonard, Edward P. Williams, C. D. Miller, T. Kerwin and J. S. Klingelsmith, of Albany; Charles Pfisger, of New York; B. B. Griffen and William Hay Bacus, of Saratoga Springs; G. G. Evertonson, Bath-on-the-Hudson.

Operating Changes in St. Louis

The St. Louis Transit Company is planning to make a number of important changes in the operating routes of its lines, and is now constructing a number of switches at different points in the city to permit making the changes. In the downtown district a number of switches are being constructed with a view to arranging loops at the eastern terminals of all the roads, and those in the west end are being constructed with a view of arranging new lines. The three most important changes will be made in the Olive Street, Channing Avenue and Southern Electric lines. The Olive Street line will be continued to Forsythe Junction, where connections will be made with the present road to Clayton; the Channing Avenue line will be a new division, and will run east from the city limits on Easton Avenue to Grand, south on Grand to Cook, east on Cook to Channing, south on Channing to Laclede and then east over the Laclede Avenue tracks on Market to Broadway; the northern terminus of the Southern electric line will be changed so as it will make a loop around Seventh, Morgan and Sixth Streets instead of going north as far as Howard Street, as at present.

Reorganization of the Chicago General Railway Company

The stockholders of the Chicago General Railway Company are in receipt of a letter outlining a plan for the reorganization of the company, which gives them permission to file, within a specified time, their holding of stock with the Real Estate Trust Company, of New York, in order to take advantage of a pending settlement and a sale of the property. Joseph P. Mahoney, William A. Goodman and Charles L. Bonney are named as a stockholders' committee, with full power to transfer and vote the stock at their discretion, and to represent all the stockholders, signing the agreement in the prospective sale of the company's property. It is said that more than $300,000 out of a total $500,000 stock issue have already been deposited with the New York Trust Company. The majority control is, therefore, already assured. This is one of the final steps taken by the Chicago General's reorganization committee to prevent a foreclosure sale under the present receivership proceedings and to protect the company's stockholders. The plan was drafted by the New York creditors of the company, who are opposed to allowing a foreclosure sale.

The fact that the Chicago General Company has valuable franchises from the city and that negotiations have several times been in progress for a transfer of these rights to the Chicago City Railway, is the basis for the new stockholders' agreement. It is reliably stated that a standing cash offer for a controlling majority of the stock is already in the new stockholders' committee's possession. Another committee representing the bondholders is also working on the same lines. This is composed of James P. Black and Lyman M. Paine, of Chicago, and Newbury D. Lawton, of New York. Practically all the outstanding bonds, except those deposited with the Merchants' Loan & Trust Company, of Chicago, and those in the possession of ex-President James H. Witbeck, have been deposited under a similar agreement with the Real Estate Trust Company in New York. The bondholders' interests are thus divided between the Merchants' Loan & Trust Company, which also represents the company's floating debt creditors; the Witbeck and King holdings, which are the subject of litigation in the courts, and the New York creditors. It is understood that an amicable settlement may soon be arranged, under which the three coteries of bondholders will pool their interests.

A Striking Advertisement

The Chicago Union Traction Company is now carrying a large advertising card in the press of that city, especially appealing to the G. A. R. guests, who are now in that city, and setting forth how Chicago may be seen for a dime. The advertisement is in large type, and is headed: "See Chicago for a Dime on the Trolley Car." In the left-hand upper corner of the card is a cut of a car well filled with G. A. R. delegates, showing in the background the outline of the great Ferris wheel, and dated Chicago, 1900, while in the left-hand lower corner is an outline picture showing

the troops on their triumphant return to Washington in 1865. The advertisement is divided into five paragraphs, each ending with the words, "ON THE TROLLEY CAR," in large type. The last paragraph ends with these words in especially large type stretching across the entire bottom of the card. The introductory words of each paragraph are in large type and are quite prominent. We reprint three of the paragraphs as they appear in the advertisement, to show how well written and forcible they are:

SPECIAL INVITATIONS are extended to the visitor this week to inspect Chicago and its suburbs and see the great changes that have taken place since the days of '61. This western town has fought its battles and won its victories until it stands to-day in the front rank of the great cities of the world. The things which make it great may be seen easily by all who are clever enough to look for them ON THE TROLLEY CAR.

ONE OF THE FORCES which has aided materially in the success of the city has been the trolley car—the great modern population distributer. The evolution from the old one-horse car of the sixties to the modern, double-truck, air-brake, electric-lighted creation of to-day, might call forth a repetition of Milton's sentiment: "Peace hath her victories no less renowned than war." The victories in the street-car field have resulted in placing the trolley car on the health-restoring, pleasure-giving list of modern inventions, so that now it is quite the proper thing to see the sights of the city, its suburbs, parks, groves, boulevards and outing resorts by going to them ON THE TROLLEY CAR.

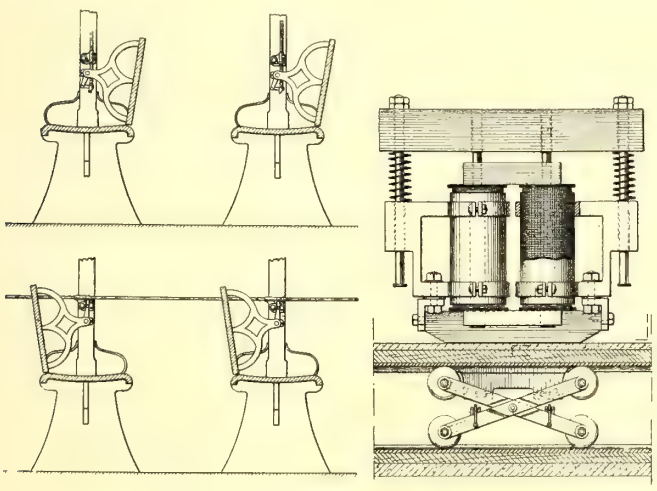
FOR SOCIAL PARTIES special trolley cars are in service going to any part of the city. There are many pleasant trips of this character around suburban Chicago, and this would be a delightful way to entertain one's friends. There are over 500 miles of tracks covered by the trolley cars in operation by the Union Traction Company on the north and west sides of town, and one may readily select a route covering a score of interesting points. If in doubt, address the general offices of the company, at 444 North Clark Street, Telephone North 736, and find out about where to go and how to get there ON THE TROLLEY CAR.

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED AUG. 21, 1900

656,183. Gate for Open Cars; C. M. Fairbanks, Central Falls, R. I. App. filed April 18, 1900. Each seat is provided with two gates, one at each end, both of which are operated at the same time by the turning of the seat, the one opening and the other closing.



PATENTS NOS. 656,183 AND 656,511

656,188. Car Seat; H. S. Hale, Philadelphia, Pa. App. filed March 20, 1900. A construction providing for the lower edge of the back clearing the surface of the seat cushion when the back is shifted.

656,207. Trolley Wheel; H. A. Osborne, Plainville, Conn. App. filed Dec. 6, 1899. The flanges of the wheel are provided with cutting ribs to remove the ice from the wire.

656,219. Seat Structure; W. L. Schellenbach, Philadelphia, Pa. App. filed July 22, 1899. Gearing is arranged between the seat and the levers, which move the seat back, so that the back will be given a certain inclination when it is swung from one side to the other.

656,226. Rail-Joint; B. Sturenberg, Alfhausen, Germany. App. filed Feb. 6, 1900. The distinguishing feature is a double wedge-shaped fish-plate lying against the suitably tapered heads and webs of the rail.

656,276. Electric Railway System; L. E. Walkins, Springfield, Mass. App. filed Dec. 15, 1898. The pressure of the car wheel first throws the switch to close the circuit to the sectional conductor, the circuit being thereafter held closed by an electro-magnet, until the vehicle has passed.

656,372. Guard for Controller Brushes; A. L. Riker, New York, N. Y. App. filed Jan. 8, 1900. The guard prevents the controller brushes from catching upon the controller segments.

656,379. Brake; G. E. Seymour and F. Kahler, New Albany, Ind. App. filed June 7, 1900. The releasing device is a button on the end of the brake staff by pushing which an instantaneous release is affected without movement of the handle.

656,381. Anti-Vibrating Car Truck; L. C. Thompson and F. Kirk, Cuyahoga Falls and Akron, Ohio. App. filed Oct. 19, 1899. The invention relates to a pair of four-wheeled electric car trucks supporting the car upon the motor drive-wheels and bracing the guide wheel in a manner to receive the vibratory shock generated at the electric motors in connection with the motor armature, including the vibration generated by the rapid revolving motion of the car wheels.

656,445. Cooling Brakes; A. Ekstrom, Schenectady, N. Y. App. filed April 27, 1898. A piping system is arranged to deliver a cooling liquid against the brake shoes to reduce the temperature due to frequent use.

656,477. Auxiliary Car Mover; P. Ryan, New York, N. Y. App. filed Dec. 29, 1899. An eccentric on the axle vibrates a pusher-bar, which acts against the roadbed.

656,511. Electric Railway System; G. L. Campbell, New York, N. Y. App. filed Dec. 15, 1899. A trolley carrying an armature is dragged through a conduit by a magnet on the car. In moving along the trolley closes the circuit between the main and sectional conductor.

656,571. Controller for Electric Motor; T. S. Perkins, Idlewood, Pa. App. filed Jan. 13, 1900. In connection with the contact fingers one or more electro-magnets and arc shields are provided, with magnetic flux conductors, which project between adjacent fingers and into proximity to the pole pieces of the magnets for the purpose of preventing arcing.

656,608. Brake Mechanism; C. E. Moore, Chicago, Ill. App. filed Dec. 23, 1899. The combination with a brake-shoe head, of a hanger for suspending or supporting the same, provided with a ball-and-socket connection between said hanger and brake shoe and a ball-and-socket connection at the upper end of said hanger between the same and the truck frame, each of said ball-and-socket connections comprising a ball and a two-part socket surrounding the ball.

PERSONAL MENTION

MR. H. J. McGOWAN, president of the Indianapolis Street Railway Company, of Indianapolis, Ind., has been elected president of the Kansas City Gas Company, of Kansas City.

MR. A. J. PURINTON, of Waterbury, Conn., has been elected general manager of the Palmer & Munson Street Railway Company, of Palmer, Mass., to succeed Mr. D. F. Burritt. Mr. Purinton will also have charge of the plant of the Central Massachusetts Electric Company.

MR. HERBERT W. SMITH has accepted a position with the Stuart-Howland Company, of 283 Devonshire Street, Boston, as assistant manager of its railway department. Mr. Smith's extensive experience in the street railway supply business well fits him for his new duties.

MR. F. I. BROWN has been elected president of the Jacksonville Street Railway Company, of Jacksonville, Fla., to succeed Mr. D. F. Jack. Mr. Jack resigned because of the pressure of his duties as general traffic manager of the Plant system. Mr. Brown is also president of the Main Street Railroad Company, of Jacksonville, and the supervision of both systems will thus be brought under one head.

MR. HENRY S. NEWTON has resigned as manager and purchasing agent of the Syracuse, Lakeside & Baldwinsville Railway, of Syracuse, N. Y., to accept the position of general superintendent of the Beaver Valley Traction Company, of Beaver Falls, Pa. Mr. Newton has previously been connected with the Consolidated Street Railway Company, of Wheeling, W. Va.; the Syracuse Street Railroad Company, and the Syracuse Rapid Transit Company.

MR. T. B. GOODYER, general traffic superintendent; Mr. H. M. Sayers, power engineer, and Mr. J. A. Lycett, district superintendent of the British Electric Traction Company, of London, England, who are now studying American electric railway practice, were in Buffalo Aug. 20. Messrs. Goodyer, Sayers and Lycett inspected the lines of the International Traction Company and expressed themselves as well pleased with the system. It is their purpose to visit Toronto, and then go to New York. They will sail for London about Sept. 1.

NEWS NOTES

WASHINGTON, D. C.—The assistant attorney for the district has forwarded to the Commissioners an opinion holding that passengers of the Brightwood Railway Company are not entitled to free transfers to the Metropolitan Railroad Company, and that the act of Feb. 26, 1895, authorizing and requiring the Brightwood Company to sell four coupon tickets for 25 cents, good for one continuous ride in the District of Columbia over the lines of the said company and the lines of the Metropolitan Railroad Company, is still in force. For the past five or six months passengers on the Brightwood road have been given free transfers at the terminus of that road for a continuous ride over the line of the Metropolitan Railroad Company. Under an arrangement announced by the Washington Traction & Electric Company these free transfers will be discontinued on Sept. 1, and passengers desiring to transfer to the Metropolitan line will be required to use a four-for-a-quarter ticket good for one continuous ride in the District of Columbia over the line of the Brightwood and Metropolitan roads, or pay cash fares.

CHICAGO, ILL.—Coal is to be substituted for oil as fuel in the Western Avenue, Hobbie Street and Rockwell Street power houses of the Union Traction Company. The plants are being fitted with automatic stokers in preparation for the change. Economy is given as the reason for the change.

PALMER, MASS.—The Palmer & Monson Street Railway Company has accepted the franchise recently granted it by the Council of Wilbraham.

NEW BRUNSWICK, N. J.—A car of the Middlesex & Somerset Traction Company ran into a freight train on the Raritan River Railroad, Aug. 20. Seven passengers, who were on the car, escaped injury by jumping from the car. The motorman and conductor remained at their posts, and both were shaken up badly.

ROCHESTER, N. Y.—Twelve persons were injured, one mortally, and forty others were in danger through an accident on the Manitou Beach Railroad at Greenway's Bluff, near Charlotte, on Aug. 24. A crowded car was derailed by the breaking of a flange, and it plunged into a gully 15 ft. below.

CLEVELAND, OHIO.—A car on the Cleveland & Chagrin Falls Electric Railway jumped the track on a curve near Chagrin Falls Aug. 22, while running at high speed. The car was wrecked and the crew and twelve passengers cut and bruised. Five persons were seriously injured.

CLEVELAND, OHIO.—The Cleveland Electric Railway Company is receiving the first of a lot of fifty double-truck cars ordered some time ago from the J. G. Brill Company, of Philadelphia. In the near future all lines operated by the company will have been equipped with these cars.

COLUMBUS, OHIO.—The employees of the Columbus Railway Company were given their fourth annual outing at Olentangy Park a few days ago. Twenty-three hundred metal badges were issued to the families of employees, furnishing free transportation and admission to the park and all entertainments to the holders. The car crews were arranged in shifts so that every employee was given a chance to participate in the festivities.

COLUMBUS, OHIO.—The Urbana, Mechanicsburg & Columbus Electric Railway Company has presented a proposition to the city for a franchise on certain city streets. The company agrees to carry passengers at the rate of 5 cents for single fare, seven tickets for 25 cents and twenty-eight tickets for $1, the fare to Urbana not to exceed 2 cents per mile. A bond for $1,000, with approved security, accompanied the proposition.

BEAVER FALLS, PA.—On Aug. 24 a closed car of the Beaver Valley Traction Company jumped the track on a steep grade, overturned and plunged into two trees, where it hung suspended 150 ft. above the Fort Wayne Railroad tracks. There were about fifty passengers on the car, many of whom were injured.

RICHMOND, VA.—The Richmond Passenger & Power Company and the Richmond Traction Company have practically agreed upon a system of general transfers, covering all the lines in Richmond and Manchester.

SEATTLE, WASH.—The Supreme Court has just handed down a decision ordering that the temporary injunction restraining the Seattle Electric Company from proceeding with certain improvements in its system, as authorized in the franchise grant to J. D. Lowman and Jacob Furth, dated March 8, be dissolved. The effect of the decision is that the ordinance granting the franchise does not violate any of the provisions of the charter of the city of Seattle, and the procedure adopted by the City Council in passing the ordinance is in substantial compliance with the procedure marked out in the charter. As an immediate result of the decision, it is said the plans of the Seattle Electric Company, for which the franchise was secured, will be put into operation, involving substantial and costly repairs to existing lines of street railway controlled by the company, the reduction of fares, the inauguration of a complete transfer system and the early commencement of work on many miles of extensions.

CONSTRUCTION NOTES

SAN BERNARDINO, CAL.—The Board of City Trustees have granted Judge J. L. Campbell a franchise for constructing and operating an electric railway over a specified route here. James H. Boyd is associate with Judge Campbell in the promotion of the enterprise.

NEW BRITAIN, CONN.—The Connecticut Lighting & Power Company only awaits the action of the Legislature before beginning work on its new line from Lazy Lane to Waterbury. With a line to Waterbury the Connecticut Lighting & Power Company will have a direct route from Hartford to Waterbury.

MERIDEN, CONN.—The directors of the Meriden, Southington & Compounce Tramway Company have voted to extend the company's lines through Cheshire to Waterbury, a distance of 15 miles. The Legislature will be petitioned at its coming session to allow the extension. When the line is built four leading cities of Southern Connecticut—New Haven, Waterbury, Meriden and Bridgeport—will be connected by trolley. The connection between New Haven with Waterbury and Meriden will be made at Cheshire, as the Fair Haven & Westville line has voted to extend its line from Mount Carmel to Cheshire, to connect there with the Meriden and Waterbury line which is planned. When the proposed extensions are built complete trolley line will be established between Hartford and Bridgeport, a distance of 53 miles.

JUNCTION CITY, KAN.—The City Council has granted Frank V. Crouch, of Carrollton, Mo., a franchise for the construction of an electric railway here. Mr. Crouch has announced that he has financial backing to the amount of $500,000, and that it is the purpose of the promoters to also erect a power plant with a capacity for furnishing light and power for industrial purposes in both Junction City and Fort Riley.

LEXINGTON, MASS.—The Lexington & Boston Street Railway Company has completed and placed in operation its extension from Bedford to Concord.

WASHINGTON, D. C.—The Council of Rockville, Md., has at last ratified the ordinance granting the Washington & Rockville Electric Railway Company a franchise in Rockville. The work of surveying for the new line has begun, and it is announced cars will be in operation in a very short time.

BOSTON, MASS.—The Boston Elevated Railway Company has just been granted a permit for the erection of a large car house on the south side of the Charles River. The new house is to be of brick and wood, and will be 506 ft. long, 34 ft. wide at one end and 71 ft. at the other. The storage capacity of the house will be 250 cars. There will be rooms for the motormen and conductors, offices, waiting room, lunch room and all conveniences. The cost of the building will be about $65,000.

LYNN, MASS.—The Lynn & Boston Railroad Company will shortly apply to the Council for franchises for the extension of its lines in two parts of Lynn. One of the locations desired is on Western Avenue at the intersection of that thoroughfare with Eastern Avenue, and provides for the continuation of the belt line over the Salem and Boston Turnpike, with a double track to the dividing line between Lynn and Salem. Another extension for which permission will be asked is from the intersection of Eastern and Western Avenues and the Salem and Boston Turnpike to Washington Street, parallel to the track now laid. The Council of Salem will also be petitioned by the company for permission to extend its lines from the dividing line between the two cities to the business section of Salem. The laying of these tracks, it is thought, would prove of great convenience to the traveling public between the two cities.

ST. LOUIS, MO.—The St. Louis County Court has granted the St. Louis & Suburban Railway Company, of St. Louis, Mo., permission to construct a track across Carson road near the city limits of Ferguson, and to cross and run over the Florissant Rock road for a short distance, forming part of a new line to Ramona Park, where connection will be made with the Florissant division to Ferguson. Practically the entire route, over 2 miles, will be over a private right of way.

LARCHMONT, N. Y.—The Larchmont Horse Railway Company has completed and placed in operation its extension from Larchmont Manor to Port Chester. On the west the line connects with the Union Railway for New York, making it possible to ride by trolley from extreme southerly end of New York City to the Connecticut State line, a distance of 32 miles.

MOUNT VERNON, N. Y.—The New York, Westchester & Connecticut Traction Company has commenced the construction of its line over the White Plains road in Bronxville, as provided for by a franchise recently granted by the village trustees. This line is a continuation of the North Mount Vernon line, of Mt. Vernon, and ultimately, it is expected, will be extended to White Plains, a distance of 8 miles.

JERSEY CITY, N. J.—The North Jersey Street Railway Company is now securing the consents of property owners for the extension of its lines in the Orange Valley. The new line will probably be a continuation of the present Central Avenue Road, which ends at Fourteenth Street. The new line will run from Fourteenth Street west on Central Avenue, through East Orange, Orange, Centre Street, Orange, to Tremont Avenue, and westerly through the Orange Valley, a thickly populated section needing trolley accommodation.

CINCINNATI, OHIO.—The Millcreek Valley Electric Railway Company has purchased a tract of land at Hartwell on which to erect a new car house and power house. It is estimated that this improvement will cost $125,000. The company will rush work on its Glendale extension, and expects to have the line completed by Oct. 1. Next spring the road will be extended to Hamilton. This branch will run over the Carthage pike to the intersection of Spring Grove Avenue, at St. Bernard; thence along Spring Grove Avenue to Chester Park, where it will connect with the Consolidated line, thus giving a direct line from Hamilton to Fountain Square, passing through the villages of Glendale, Wyoming, Lockland, Reading, Hartwell, Carthage, Elmwood Place and St. Bernard.

STREET RAILWAY JOURNAL

WEEKLY NEWS ISSUE

SATURDAY, SEPTEMBER 8, 1900.

PUBLISHED WEEKLY BY

THE STREET RAILWAY PUBLISHING COMPANY

MAIN OFFICE:

NEW YORK, BEARD BUILDING, 120 LIBERTY STREET.

BRANCH OFFICES:

EDITORIAL NOTICE.

The news issues of the Street Railway Journal are devoted primarily to the publication of street railway news and current happenings related to street railway interests. All information regarding changes of officers, new equipments, extensions, financial changes and new enterprises will be greatly appreciated for use in its columns.

All matter intended for publication must be received at our office not later than Wednesday morning of each week in order to secure insertion in the current issue.

Address all communications to

THE STREET RAILWAY PUBLISHING CO
120 Liberty Street, New York.

Consolidation of Southern Jersey Companies

On Sept. 1 the consolidation of the Camden Gas Light Company, Camden Gas & Fuel Company, Camden & Burlington Gas & Electric Company, East Side Gas Company, the Gloucester Electric Company, the Consumers' Gas Company, of Woodbury, Woodbury Electric Light & Power Company, and the Camden, Gloucester & Woodbury Electric Railway Company was completed as the South Jersey Gas, Light & Traction Company. Among those interested in the new company are: Anthony Kuser, Thomas N. McCarter, Jr., David Beard, William J. Thompson, John J. Burleigh and Charles H. Watson.

Sale of Fort Worth Roads

The sale of the City Railway and the Fort Worth Street Railway, of Fort Worth, Texas, to the Coffenberry-Bishop syndicate, of Cleveland, O., is announced. It is said that $400,000 was paid for the properties. The combined systems have 19 miles of track and thirty-two cars. The Coffenberry-Bishop syndicate is also interested in the Dallas & Fort Worth Electric Railway, which is now constructing a line between Dallas and Fort Worth. With the city lines in Fort Worth and the interurban line between Dallas and Fort Worth, they will have a very complete system. R. S. Vivian, of Chicago, completed the negotiations for the transfer.

Land Owners' Road Rights

Judge Landis, of Lancaster, Pa., has just rendered a decision in which he holds that electric railway companies cannot force themselves into neighborhoods where they are not wanted, and that the owners of land control a thoroughfare to its middle. In rendering his decision the judge holds that, the principle having been settled that the right of the soil of a highway resides in the properties of the land over which it has been laid, the plaintiff controls one side of the road, on which the company may not build, but they may build on the other half, if the owner of abutting property does not object, and no damage is done the plaintiff's property.

The G. A. R. Reunion and Chicago Traffic

The G. A. R. reunion held in Chicago last week was responsible for an increase in the street railway traffic such as has not been experienced by the roads for some time. No official figures of the number of passengers transported are obtainable, but the cars were taxed to their utmost capacity at all times. The companies had early realized that there would be some difficulty in handling the crowds, and had every available car in commission. However, it is not expected that the companies could meet the sudden demand made by such a big event, and considering all things there was no cause for complaint. The crowds were handled as expeditiously as could be expected under the existing circumstances.

Justifiable Profanity

Judge Mills, of Washington, D. C., has created somewhat of a sensation by discharging a prisoner arraigned before him on the charge of using blasphemous language, saying that the defendant was justified in using profane language, and that the act was praiseworthy. Swearing is against the law in Washington, and those arrested on a charge of this kind are usually convicted and punished. The prisoner, when arraigned, said that the recent changes in the transfer system of the lines of the Washington Traction & Electric Company had led him to swear, and freely admitted that he had used rather harsh language. The judge said that the changes in the system had resulted in many complications, and, after a lengthy rehearsal of the facts by the prisoner, finally discharged him, saying that the act was justifiable in his case.

Railway Suggestions Invited by Mail

After careful consideration the Chicago Street Railway Commission has decided to invite suggestions by mail from the residents of the city on the traction situation. A number of questions are now being prepared by the commission, on which it especially desires the public at large to express its opinion. The object is to obtain the popular side of this absorbing topic, and this was considered the most expeditious way to obtain it. Among the questions to be asked are the following:

Do you want the city to own and operate the street railways, or would it be more satisfactory for the municipality to hold title in

the rails and lease their use to the different companies which may desire to furnish accommodation to the people?

How would a subway system equipped with all the conveniences known to modern engineering suit you?

In the event of the city authorities extending the franchises of the companies what term would you fix as the limit?

Chicago Companies Deny Right of the City to Compel the Lowering of Tunnels

The Chicago Union Traction Company, West Chicago Street Railway Company and the North Chicago Street Railway Company have filed a general denial in the Circuit Court of the right of the city to compel the lowering of the street railway tunnels beneath the river. Petitions asking the enforced lowering of the three tunnels, at Van Buren, Washington and La Salle Streets, sought the issuance of the order on the ground that the use of the river as a natural highway was being obstructed by the tunnels. Changes in the draft of vessels in the lake carrying trade making a water depth of at least 21 ft. necessary were advanced in support of the proposition to compel the lowering of the tunnels. The jurisdiction of the city to clear the river of all obstructions was declared to be absolute, and the ordinance of March, 1900, was quoted commanding the lowering of the tunnels. The answers of the three companies deny that the tunnels are an obstruction; that the city has no jurisdiction, and that the ordinance is void and in violation of the clause of the Federal Constitution, which declares that no State shall pass any law impairing the obligation of contracts.

Accident Fakir Cleverly Trapped

A systematic attempt to swindle street railway companies throughout the country was made public Sept. 1, when Frank Lieblang, of Cleveland, was arrested in Harper Hospital, Detroit, on the charge of obtaining money under false pretenses. Joseph A. Hosman, a detective in the employ of the Cleveland Electric Railway Company, was engaged to shadow Lieblang and set a trap to catch him. Lieblang's plan was to fall from a moving car and claim to receive serious injuries, his claims being substantiated by a physician who was in the plot. Lieblang owns a saloon in Cleveland, and Hosman gained his confidence by hiring out as a bartender. Later Hosman entered into a plot to swindle a Detroit railway. Last Tuesday he fell from a car in Detroit, and although he states that he received no other injuries than a sprained wrist, he managed through tricks shown him by Lieblang to deceive the surgeons into believing he was badly injured. He was taken to a hospital, and Lieblang conducted negotiations with the street car company, and obtained $200 as a settlement. He was arrested when he went to the hospital to divide the money with Hosman. Hosman says they tried the accident game in New York, but failed. Lieblang has a suit for $10,000 damages pending against the Cleveland company. Last winter he is said to have secured a verdict against the city of Cleveland for $5,555 for injuries suffered by falling into a hole. The Cleveland company has sent H. J. Latimer to Detroit to assist in the prosecution of Lieblang.

International Tramway Congress

The programme of the International Tramway Congress, to be held at Paris Sept. 9-13, has been made public by the executive committee. The list of papers to be presented at the congress was published in the Street Railway Journal for March, page 258. The social programme is as follows:

On Sunday, Sept. 9, at 9 o'clock in the evening, there will be a social meeting of the delegates at the Continental Hotel. The first regular session of the congress will be held on Sept. 10, at 10 a. m., at which the papers by Messrs Géron and Pirch will be presented. At 2 o'clock in the afternoon a visit will be made to the Metropolitan underground road, and a trip will be taken to the Vincennes Exposition. Return will be made by electric tramway cars. The second regular session of the congress will be held on Sept. 11 at 9 a. m., at which the papers of Messrs. Gunderloch, Thonet, d'Hoop, Van Vloten and Fischer-Dick will be presented. At 3 o'clock in the afternoon a reception will be extended to the delegates at the City Hall by the municipal authorities, after which a trip will be made to the electrical subway of the Orleans Railroad Company. The session on Thursday, Sept. 12, will be called to order at 9 o'clock in the morning, and papers will be presented by Messrs. Broca, Johannet, de Burlet and Ziffer. The afternoon will be devoted to a visit to the compressed-air station of the General Omnibus Company, and the electric-power station of the West Parisian road at Moulineaux. On the morning of Friday, Sept. 13, the final papers and schedules for the congress will be presented by Messrs. Macloskie and Monmerqué. In the afternoon a visit will be made to Saint Germain, and in the evening a banquet will be held at the Palais d'Orsay.

The officers and official delegates to the congress are as follows:

HONORARY PRESIDENT

Baudin, Pierre, Minister of Public Works.

GENERAL COMMITTEE

President

Janssen, Léon, general manager of the Société anonyme les Tramways Bruxellois, Brussels.

Members

Messrs. Aigoin, president of the Compagnie generale parisienne de Tramways, Paris.

Broca, manager of the Compagnie des Tramways de Paris et du Department de la Seine, Paris.

Cuvinot, Senator and president of the Compagnie generale des Omnibus, Paris.

Fuster, secretary of the Union des Tramways de France, Paris.

Géron, manager of the Société des Tramways de Cologne, Cologne.

Guary, manager of the Compagnie generale francaise de Tramways, Paris.

Kessels, manager of the Société generale de chemins de fer economiques, Brussels.

Köhler, manager of the Grosse Berliner Strassenbahn Gesellschaft, Berlin.

Lavalard, associate manager of the Compagnie generale des Omnibus, Paris.

Monmerque, chief engineer of Bridge and Highways, chief engineer of the Compagnie generale des Omnibus, Paris.

Radice, president Italian Tramway Association, Milan.

Röhl, manager of the Société des Tramways of Hamburg.

Ziffer, president of several railway companies in Austria, Vienna.

General Secretary

Nonnenberg, F., manager of several street railway companies, Brussels.

Secretary

Janssen, Albert, manager of the Société des Tramways Bruxellois, Brussels.

DELEGATES APPOINTED BY DIFFERENT GOVERNMENTS

Austria

Edler von Leber, Max, ministerial councillor, Vienna.

Strzizek, Franz, chief engineer, Vienna.

Freund, Ludwig, imperial councillor and chief engineer of the State railways of Austria.

Belgium

Janssen, L., general manager of the Tramways Bruxellois, Brussels.

Nonnenberg, F., manager of several tramway companies, Brussels.

Janssen, A., manager of the Tramways Bruxellois, Brussels.

Nyst, F., engineer at Liége.

Canada

Mavor, James, professor of political economy at the University of Toronto, and commissioner general of Canada at Paris.

France

Plazen, appointee of the Minister of Agriculture, Paris.

Holland

Van Leuwen, J., engineer of the State Railways, the Hague.

Hungary

Kadar, G., technical councillor, Buda-Pest.

Monaco

Bergés, P. A., manager of public works, Monaco.

Roumania

Remush, A., forestry engineer, Paris.

Russia

Redel, Commissioner General of Russia at Paris.

Siam

Hoeylaert, H., Consul General of Siam at Brussels.

Rolin, E., Consul General of Siam at Brussels.

Sweden

Fränckle, Member of the Industrial Chamber, Stockholm.

Spain

Pedro Garcia Faria, Commissioner General of Spain at Paris.

United States

Colonel Truesdell, G., president of the Capital Traction Company, Washington.

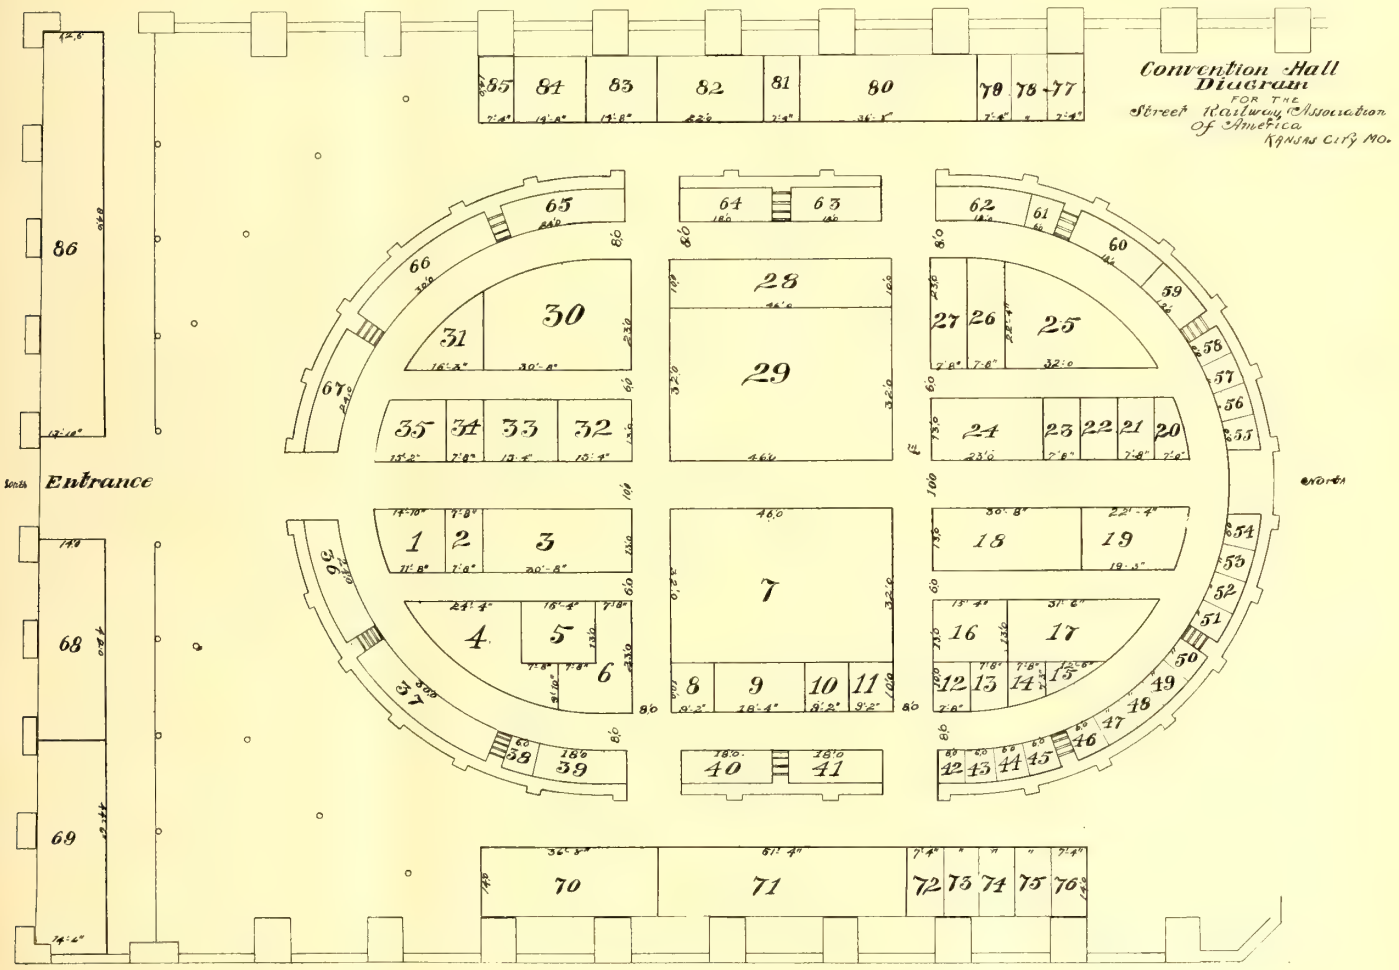
Professor Wilkins, F. S., professor of civil engineering, University of Alabama and assistant in department of transportation.

Allen, W., secretary Massachusetts State Commission.

Assignment of Exhibit Space for American Street Railway Association Convention

A plan showing the exhibit space in Convention Hall, at Kansas City, together with the names of exhibitors and the number of square feet engaged by each, is presented herewith. This is up to date, and leaves only a few spaces not yet taken:

No. of Space	Name of Exhibitor	No. Sq. Ft.
16	Atlas Railway Supply Company	200
22	American Railway Supply Company	100
33	Garton-Daniels Company	200
19	Gold Street Car Heating Company	300
29	General Electric Company	1,500
9	Garl Electric Company	200
25 and 26	Hipwood-Barrett Manufacturing Company	620
66	International Register Company	200
3	K. C. Car & Foundry Company	400
86	Lorain Steel Company	1,000
20	Leschen, A., Sons Rope Company	100
24	McGill, Porter & Berg	300
27	Manville Covering Company	200
36	McRoy, John T.	160
83	Merritt Electric Air Brake Company	200
85	Magann, G. P., Air Brake Company	100
23	National Lead Company	100
65	New Haven Car Register Company	160
42 to 45	Nuttall, R. D., Company	160
4	Ohio Brass Works	400
60	Ohmer Car Register Company	120
67	Pittsburgh Reduction Company	160
68	Peckham Truck Company	500



5	Adams & Westlake Company	200
28	American Car & Foundry Company	500
13	American Brake Shoe Company	100
18	Brown, Harold P.	400
63	B. R. Electric Company	120
10	Bierbaum & Merrick Metal Company	100
6	Curtain Supply Company	300
17	Chisholm & Moore Manufacturing Company	400
30	Christensen Engineering Company	800
62	Chicago Mica Company	120
32	Consolidated Car Heating Company	200
15	Continuous Rail-Joint Company	50
31	Cutler Hammer Manufacturing Company	150
80	Compressed Air Company	500
84	Creaghead Engineering Company	200
37	Dixon, Joseph, Crucible Company	200
12	Diamond State Steel Company	100
51, 52 and 53	Dearborn Drug & Chemical Company	120
34	Electrical Review Publishing Company	100
59	Pomeroy & Fisher	80
8	Pantasote Company	100
55 to 57	Partridge Carbon Works	120
40	Ridlon, Frank, Company	120
1	Street Railway Review	200
35	Street Railway Journal	200
64	Scott, Charles, Spring Company	120
21	Standard Paint Company	100
11	Standard Underground Cable Company	100
54	Spiral Journal Bearing Company	40
69	Taylor Electric Truck Company	500
39	Trojan Button Fastener Company	120
82	Wharton, William, Jr., & Company	300
41	Wood, Charles N.	120
7	Westinghouse Electric & Manufacturing Company	1,500
71	Westinghouse Air Brake Company	700
14	Weber Railway Joint Manufacturing Company	100
2	Western Electrician	100
81	Wheel-Truing Brake Shoe Company	100

Notes From Germany

[*From Our Regular Correspondent.*]

A new telegraph law went into force this year permitting the postal department to utilize public roads for the stringing of telegraph and telephone wires. The effects of these new rights are now being slowly felt. Because the departments could in the past demand payment from individuals or companies who interfered with their lines or caused disturbances therein, Parliament was reluctant to pass the new law. The municipalities claimed that in case they wanted to build roads themselves, they would not even be masters of their own highways. Parliament finally decided that the postal department could demand payment for damages done by private parties, but not by the owners of the highways, *i. e.*, the municipalities. Should the road be purchased by a private party, then the latter must pay for any expense incurred by the department in protecting its lines. This law is of great importance to municipalities, as they can now build roads more cheaply. Formerly the expense of removing telegraph and telephone lines was frequently greater than the building of the road itself, as, for example, in the case now existing at Wiesbaden.

The fact that the State government has, within recent times, frequently granted an extension of franchises to private companies without referring the matter to the municipalities which own the highways, has induced the various city governments to adopt resolutions plainly showing to the State authorities that in the future they will build electric roads themselves. It is, however, not the intention of the cities to operate small, unprofitable roads in connection with an established city railway system, but they want to embody the condition that every party to whom a franchise is granted must have operated a road before. At the same time the cities are gaining valuable experience in the running of roads and the training of employees, but to anybody trained in electric railway practice it is clear that they do not fully realize what is required of a capable superintendent. The cities of Berlin, Charlottenburg and Breslau have adopted such resolutions.

On several much frequented streets of Berlin, such as on Leipziger Strasse, the police department had forbidden the use of trailers, on the ground that the length of motor car and trailer greatly interferes with the traffic. This action was firmly supported by the cab proprietors, who were jealous of the cheap transportation furnished to people by the trailer system, and based their complaints on the doubtful assertion that the trailers were very dangerous. Recent statistics in regard to accidents, however, prove that more accidents are due to motor cars than to trailers, and this has induced the police department to reverse its decision and permit trailers on all streets. This is of importance, as all the large lines connecting the east with the west of Berlin must pass through Leipziger Strasse, and a direct and uninterrupted traffic is thus afforded. In Germany the cost of running a trailer is about one-half of that required to operate a motor car.

As in America, it is found in Germany, that the suburban electric car lines seriously affect the traffic of the heavy steam roads. This is evidenced by frequent notices posted by the railway companies, of which the following is an example: "On account of the recent opening of the electric road, it has been observed that the traffic has been considerably reduced on our suburban trains. On the first two trains there are, on an average, fourteen passengers, and on the last two trains thirteen, so that we feel justified in discontinuing these trains on week days."

The recent trial trips on the Wannsee electric road have induced the military authorities to continue the experiments on the military road, which connects Berlin and Mariendorf with the artillery proving grounds at Zossen. The trials are being conducted by a Berlin company devoted to high-speed electric roads, called the Studien Gesellschaft. Siemens & Halske and the Allgemeine Elektricitäts Gesellschaft will each furnish a motor car which has to meet the following requirements: The cars are 26 ft. long, seat sixty people, and weigh 70 tons. Three-phase current is furnished by the central station at Oberspree at a pressure of 12,000 volts. In the cars themselves this is reduced by means of transformers to 1000 volts. It is desired principally to show by these trials that the desired speed of 200 km per hour can be attained.

The electric omnibus line which began operations in Berlin a few weeks ago may be considered a formidable competitor of the electric street car lines. On the opening day a number of invited guests were met at 7 o'clock at the charging station in front of the Stettiner depot, by Director Meyer, of the company, who welcomed them and invited them to enter a gaily decorated bus. Several streets were traversed and the line then declared open. The eight buses followed at a headway of nine minutes. In equipment the buses resemble those of the already existing line. The fare over the entire line is 10 pfennigs; but certain distances may be traveled over for 5 pfennigs.

The Grosse Berliner Strassenbahn, which had already consolidated with it the South and West Berlin suburban lines, as well as the new Berlin horse-car line, has recently purchased the majority of the shares of the accumulator road from Berlin to Charlottenburg. This was accomplished so secretly that nothing was known of it until the deal was completed. The scarcity of money recently induced a banking house owning most of the shares to sell the same to the Grosse Berliner Strassenbahn. The Berlin-Charlottenburg road paid last year a 3 per cent dividend and a 5½ per cent dividend in the previous year. The transfer price is 142 per cent, so that the stock is being well paid for. It should be remarked in addition that the purchased company's franchise was also extended until 1950, which, for German conditions, is a very long time. The capital stock of the Berlin-Charlottenburg road is M.9,000,000. It possesses one hundred cars, while the Grosse Berliner road has 2000.

As all the cases which arose out of the recent Berlin strike are about settled, it is found that 150 years in prison is the total punishment for the offenders. Aside from these, however, there is still a civil case to be settled, which is of more than usual interest. The advertising window panes in the cars belonging to a certain firm were destroyed by the mob. The firm now demands, in view of a certain law which holds the city responsible for property at the time of a public riot, that the city authorities pay for the damaged panes. The latter refused the demand, and pointed to an agreement between the city and the railway company which stated that the city cannot be held responsible for damage done to the company's property, if the same is caused by riots. The firm claims, however, that this private agreement does not have any bearing on the case, and the company claims that it is responsible for damage done to its own property but not to that of others. The decision is awaited with a great deal of interest.

The annual meeting of the "Verein Deutscher Strassenbahn und Kleinbahn Verwaltungen" will be held at Wiesbaden on Sept. 6, 7 and 8, 1900. The programme is as follows: Sept. 5, in the evening, general reception of the delegates. Sept. 6, at 9. a. m., general business, reading of papers and discussion; at 1 p. m., lunch; in the afternoon, sightseeing; in the evening, a dinner. Sept. 7, at 9 a. m., reading of papers and discussion; at 1 p. m., lunch; in the afternoon, short trips, and in the evening, the official dinner. Sept. 8, in the morning, a trip to Rüdesheim by special steamer; from there to Cologne. On Sept. 9, the trip is continued by the delegates to the international congress at Paris, which takes place from Sept. 10 to 13

The papers to be read at the meeting and the discussions are as follows: (1) Annual report. (2) Report on the accidents during 1899. (3) Brakes for electric street cars. (4) Construction of cars suitable for suburban and city tracks. (5) Report on the recommendations of the Elektrotechnische Verein in regard to safety appliances for electric street cars. (6) The wages movement of the employees. (7) Calculations in regard to cost of operation of two and four-axle motor cars and trailers. (8) The taxation of right-of-way agreements. (9) The adherence to the limits imposed by the small-roads law and the working of section 96. (10) Report on the transportation facilities at the Paris Exposition. (11) Report of the literary committee. (12) Discussion in regard to the possibility of the society gathering statistics in regard to German street railways, as suggested by the Imperial Minister of Public Works. (13) Report on the question in regard to the removal of snow and ice during the winter of 1899-1900. (14) Planning the society's work for 1900-1901. (15) Choice of the next meeting place.

The walls of the power station for the electric elevated and underground road of Berlin are finished. When completed the lower portion of the station will contain the machinery. This consists of three large steam engines of 900 hp each, having a speed of 115 r. p. m., and three direct-current generators, each having a capacity of 800 kw. On the upper stories are the boilers. Above these the coal pockets are located, which are supplied with coal by means of Hunt conveyors. The boilers and engines are now being installed. The chimney is completed, and has a height of 80 m (262 ft.).

A most emphatic protest against the free and frequently unnecessarily large use of oil at railway curves has been recently entered by the bicycle clubs and owners of automobiles, having pneumatic tires. The effect of the oil on the rubber of the tires is most injurious. It is quite probable that the ordinance demanding the use of expensive lubricants will soon be abolished, especially as it also proved to be a good insulation between wheel and rail, and greatly hampered the climbing of grades.

Experiments With Electric Traction on Trunk Railways*

BY N. H. HEFT
(Chief of electrical department, New York, New Haven and Hartford Railroad Company)

(Continued from page 788.)

Can trains be shifted at stations and yards as quickly?

Yes. When operated by third rail, motor cars can be run around train without turntable or other delay. When operated by overhead trolley a slight delay is caused by the necessary shifting of the trolley.

Can trains be run over frogs and through yards at same speed?

Yes, when operated with third-rail system. With overhead trolley system, provided the trolley is looked after and kept on the wire when passing through overhead frogs.

Can coaches be economically heated, and how would cost compare?

No. Experience has shown in the New England States, during the average winter weather, that a coach 60 ft. in length will require from 6 kw to 12 kw, and figured at the rate of 1 cent per kw-hour, costs from 6 cents to 12 cents per hour. With the temperature at zero the cost would be 18 cents per hour. From the best data received, the cost of heating the same coach with steam from locomotive in ordinary weather would be 2 cents per hour; zero weather, 3 cents per hour.

Can coaches be satisfactorily lighted, and how would cost compare with oil or gas?

Yes. The New York, New Haven & Hartford Railroad Company places thirty lamps of 16 cp in a 60-ft. coach. These lamps would consume 1500 watt-hours or 1½ kw-hours. At 1 cent per kw-hour the cost would be 1½ cents per hour, and, taking into consideration the cost of necessary attention, with oil or gas, would be fully as economical and more desirable.

Will the use of electric traction increase or decrease wear on tracks per train-mile run.

With electric locomotives or motor cars of equal weight, the wear on service rails would be less, due partially to the rotary application of the power and partially to the fact that with electric motors no dead weight need be carried outside of weight on driving wheels necessary for traction.

How will passenger receipts be affected by more frequent service of lighter trains?

The receipts will be increased, as shown by a comparison of the number of passengers carried by the New York, New Haven & Hartford Railroad Company on the Nantasket Beach, Highland, Berlin and New Canaan branches, with steam trains, and electric trains with more frequent service.

	Steam	Electric
Nantasket Beach	304,292	702,419
Highland division	387,695	1,060,617
Berlin branch	267,936	241,207
New Canaan branch	98,302	184,728

What kind of coach will be most satisfactory to the traveling public?

The local conditions govern as to the most desirable coach. For summer travel the open car is most desirable, provided speed does not exceed 20 miles per hour; for spring, fall and winter travel the closed coach with cross seats, center aisle, toilet room and water coolers.

On lines traversing the seashore the open coach is most desirable. The ideal coach is one that can be changed at will from an open to a closed coach. To meet the views of President Clark, who has long been a believer in the use of coaches of less weight for suburban and branch lines, and of such a design as would make the same available for both summer and winter service, the New York, New Haven & Hartford Company has designed such a coach for service on its Providence, Warren & Bristol branch, now being equipped for electric traction.

Maximum speed at which to run open cars?

Not to exceed a train schedule of 14 miles to 15 miles, including stops, with a maximum speed of 20 miles per hour between stations.

Will electric traction on main lines between towns and cities, with frequent service, higher speed, and equal fare, be more attractive than the street railways which parallel the steam lines, cover the same terminals, take up and leave passengers at their own doors, but consume more time?

Yes. Experience on two main steam railroads shows that after the substitution of electric traction they have not only regained the lost travel, but have made monthly gains during the last two years, showing that the passenger will travel by the shortest route, even when other conditions are not equal.

What is the maximum distance that power can be transmitted economically by direct current?

Ten miles to 15 miles under ordinary conditions on main lines.

What is the maximum voltage allowable in the working conductor when using direct current?

Experience with third-rail systems has demonstrated that 700 volts can be maintained on the working conductor without giving trouble. With voltage exceeding 700, arcs and short circuits are hard to prevent. Owing to difficulties of motor insulation and commutation with voltages much higher than 700, the same limit may be taken for all forms of working conductors.

Can freight trains be operated?

Yes. The Baltimore & Ohio Railroad Company operates all passenger and freight trains passing east and west through the city of Baltimore over its main trunk line, and the writer is advised that the service operated is satisfactory from every standpoint.

The Erie Railroad Company leased its branch line between Buffalo and Lockport to the Buffalo & Niagara Falls Electric Railway, which has been operating a freight service with special electric locomotives. The management reports that this service is operated, in connection with passenger, mail and express, most satisfactorily.

There are several other railways operating a freight service with equal success.

For weights of trains operated by the Baltimore & Ohio Railway Company, see their answers, Appendix. Trains of fifteen to twenty cars, each loaded with 30,000 lbs. of freight, are operated on the Buffalo & Lockport line.

What should be the location and equipment of motor car house?

The motor car houses should be located at the most central point, preferably close to the power station; this will allow the use of either steam or electricity for power required in the maintenance of motors and cars. The design should provide for the repair shop being placed under house tracks, provided with power hoists, so arranged that motor cars can be run over them. Power jacks should be provided to lift coach body from trucks, to permit cables and brakes to be quickly disconnected and allow the dropping of the trucks into the repair room below. The motors and trucks being interchangeable, this arrangement allows the replacing of motors or trucks with a minimum loss of time. The repair shop should be provided with tools for making repairs only, it having been found to be in the line of economy to purchase repair parts from the manufacturers.

Are motors satisfactory?

Experience in the use of heavy railway motors is limited to the past five years, and there are but few distinct types. The first motors followed the light railway practice by the adoption of four poles instead of two. These motors were so wound as to produce two salient and two consequent poles. The motor frame completely enclosed the armature, and no provision was made for ventilation. The bearings were insufficient in size, the journal brasses or linings were badly designed, and the methods of lubrication were crude. The air gap, or distance between the armature and the pole faces, was so small that a slight wear on the armature-bearing brasses was sufficient to allow the former to drop down and come in contact with the lower pole face, which immediately disabled the motor by burning out the armature. The experience of the railway managements, operating these motors, quickly developed the above defects, and their demands upon the manufacturers resulted in the design of a motor with increased power, with four salient poles, a much larger air gap, greatly improved journal boxes, and a method of lubrication which is satisfactory. In the method of ventilation, and the general design of the gear cases, there is room for radical improvement. These motors are geared to the axles by a single pair of gears, but in the heaviest type of electric locomotives the armatures are mounted directly upon the axle.

The experienced gained in the operation of heavy electric railway motors shows that the work that they are called upon to perform is even more severe than that required of steam locomotives. They are required to attain an equal if not greater schedule speed. The number of miles run per day is from 200 to 400, which is much more than is required of any steam locomotive in regular service. With such conditions existing, it is evident that the strictest care must be exercised in the design of the mechanical details of motors and in their maintenance.

Are motor trucks satisfactory?

In the design of a motor truck, special attention should be paid to strength of frame, size and composition of wheels, dimensions of axles, springs, brakes and the motor suspension. A motor truck carrying two heavy motors in some cases weighs 25,000 lbs.

* Abstract of paper to be presented at the International Railway Congress, Paris, Sept. 20-29.

The wheels should be standard, with steel tires. It should not be forgotten that, as these trucks are to do the work of a steam locomotive, the axles should be of proportional strength. Experience on the New York, New Haven & Hartford Railroad with light axles, considered to be of ample dimensions for the required service, demonstrated to the management that the motor axles must be increased in size. The standard axle adopted by this company for motor trucks is 8 ins. in diameter at gear wheel hub, and 6½ ins. at motor bearing and wheel fit with journals 5½ ins. x 9 ins. These axles are oil tempered and have 1½-in. hole through the center.

The brakes should be arranged without a brake beam, for convenience in inspecting motors.

The form of motor suspension is of great importance. The ordinary method used on heavy roads is to hang the rear end of the motors in journals on the axles, while the front end is supported by springs attached to the bolster of the truck. This method has serious disadvantages. The truck springs, having to support half the weight of the motors, as well as the coach body, are necessarily made larger and heavier than usual. The uneven strain on these springs, in addition to their being unnecessarily heavy for the coach body, produces a rigidity, causing the coach to ride with discomfort when partially loaded. The motor suspension now used by the New York, New Haven & Hartford Railroad Company differs from the above in that the motors are supported entirely by the axles, no part of their weight being carried by the truck frame or the springs supporting the coach body. This is accomplished by the use of two equalizing suspension bars, which extend from one axle to the other beneath, and on each side of, the motors. These bars are supported at their ends by links, which are held by lugs cast on the motor frames, directly under the motor axle bearings.

With the present railways motors, it has been demonstrated that either heavy or light trains can be operated over the same tracks, and can perform any service required of the steam locomotive. These motors can be mounted on trucks, as with either one or two motors on each truck. The coach then becomes the locomotive. Its whole weight is available for traction, and, in addition, it has a seating capacity equal to any coach operated with the steam locomotive. A coach such as is used on the Highland division of the New York, New Haven & Hartford Railroad, having a seating capacity of seventy passengers, equipped with two motors on one truck placed under one end, and using a standard passenger truck on the other end, can be used as a single car during the hours when travel is light, with trail coaches added, as required, during the hours of heavy travel. Two coaches in addition to motor car used on this line, make a train weighing 161,000 lbs., and operating a train schedule of 30 miles per hour, including stops. The seating capacity of such a train is 174 passengers. With two motors on each truck placed under such a coach, we have a locomotive with 100,000 lbs. on drivers, and a total weight, including pasengers, of 110,500 lbs. available for traction, when carrying seventy passengers.

A comparison with a standard steam locomotive designed for suburban service is of interest. It shows the total weight to be 166,000 lbs., with 72,000 lbs. on drivers, leaving 94,000 lbs. as dead weight, and not providing any passenger seating capacity.

The results obtained with electric traction on main line railroads demonstrate that the present application of this power is no longer experimental; that it will rapidly supersede steam on lines where travel is heavy and congested, and where, for economy in operation and increased passenger receipts, a frequent service is necessary.

This mysterious and silent power will undoubtedly continue to grow in popularity, taking an advanced position among the known motive powers of the world.

APPENDIX

In the series of answers given below:

A stands for Plymouth division of N. Y., N. H. & H. R. R., Nantasket Junction to Pemberton; Braintree to Cohasset.

B stands for Highland and Hartford divisions of N. Y., N. H. & H. R. R., Berlin to New Britain.

C stands for New York division, Stamford to New Canaan, of same road.

D stands for Pennsylvania Railroad Company, Bordentown and Mount Holly branch.

E stands for Baltimore & Ohio Railroad Company, Baltimore Belt Line.

---

1. Do you use electric traction? As an experiment? Or in regular service?

A. Yes. No. Yes. *B.* Yes. In regular service. *C.* Yes. No. Yes. *D.* Yes. In regular service. *E.* Regular service.

2. Describe in a general way the system or systems you have adopted?

A. Nantasket Junction to Pemberton, overhead trolley; center bracket construction; double track. Braintree to Cohasset, third-rail construction, overhead trolley at stations. *B.* Third rail, direct-current system. *C.* Overhead trolley construction, flexible brackets on octagonal wood poles (30-ft. x 10-in. butt x 8-in. top), supporting 000 and 0000 round wire. *D.* Westinghouse. *E.* Overhead trolley—using an iron conductor made up of two Z bars 3 ins. x 3 ins. x ⅜ in. covered with 12-in. x ¼-in. plate.

3. On what lines are they in use and how long have they been in operation?

A. Plymouth division, summer months. Nantasket Junction to Pemberton, five years; Nantasket Junction to East Weymouth, four years; Nantasket Junction to Braintree, via East Weymouth, two years; extension from Nantasket Junction to Cohasset, one year. During Summer months only. *B.* Highland division, Hartford to Bristol, Hartford division, Berlin to New Britain, two years three months. *C.* New Canaan branch on New York division. Has been in operation since 1898. *D.* Burlington branch, Camden and Burlington County Railroad, Amboy division, Pennsylvania Railroad Company. Since July, 1895. *E.* Used on the Philadelphia division of Baltimore & Ohio Railroad. Have been in operation nearly four years.

LINE OR TRACK

4. Give the length of the different lines operated by electricity?

A. Nantasket Junction to Pemberton, 7.0 miles; Braintree to Cohasset, 10.5. Pemberton service continued from Nantasket Junction to Braintree over same tracks. *B.* Hartford to Bristol, 18 miles; Berlin to New Britain, 3 miles. *C.* 7.66 miles. *D.* 7.1 miles. *E.* Belt line, 4 miles in length.

5. The type of rails used and their weight per yard?

A. Nantasket Junction to Pemberton, 76-lb. T; Braintree to Cohasset, 100 lbs., 6 ins. *B.* Steel T-rail, 74 lbs. per yard. *C.* 4¾-in. T-rail, 72 and 74 lbs. per yard. *D.* T-rail 56 to 70 lbs. *E.* A. S. C. E. standard, 85 lbs. to the yard.

6. Single or double track?

A. Double throughout. *B.* 18 miles single, 3 miles double. *C.* Single with turnouts. *D.* Single track. *E.* Double.

7. Give the maximum grade and curvature?

A. Maximum grade on Pemberton section, 1.07 per cent; on Braintree section, 0.687 per cent. maximum curvature at Braintree, 15 degrees; maximum curvature on Pemberton section, 10 degrees. *B.* 65 ft. per mile; 10 degrees. *C.* Maximum grade, 52.8 ft. per mile, 1 per cent; maximum curvature, 7 degrees. *D.* Maximum grade, 80 ft. to mile; 310-ft. radius at Mt. Holly. *E.* Maximum grade, 1.5 per cent; curvature, 10 degrees.

8. Gage of track?

A. 4 ft. 8½ins. *B.* 4 ft. 8½ ins. *C.* 4 ft. 8½ ins. *D.* 4 ft. 8½ ins. *E.* 4 ft. 8½ ins.

9. Character of ballast used?

A. Gravel and sand. *B.* Gravel. *C.* Gravel. *D.* Cinder and gravel. *E.* Stone.

10. Wood or metal ties?

A. Wood. *B.* Wood. *C.* Wood. *D.* Wood. *E.* Wood.

11. Describe the type of rail-joint?

A. Standard angle bar fastened with four ¾-in. bolts. *B.* Four-bolt and six-bolt angle spliced bar, suspended joints. *C.* Standard angle bars fastened by four ¾-in. bolts. *D.* Angle splice bar. *E.* Continuous.

12. Give number of highway crossings at grade?

A. Pemberton section, 9; Braintree section, 27. *D.* Twelve. *E.* None.

POWER STATIONS

13. Give the number of power stations for each line?

A. One. *B.* One for all. *C.* One. *D.* One. *E.* One.

14. The position of the power stations relative to the line?

A. One mile from Nantasket Junction on line toward Pemberton. *B.* At the outer end of the 3-mile line joining the center of the 18-mile line. *C.* At Stamford end. *D.* East end of line. *E.* At one end.

15. Their rated capacity in kilowatts?

A. 1100 kw. *B.* 1700 kw. *C.* 600 kw. *D.* 200 kw equal to 266 hp to switchboard at 100-lb. steam pressure. *E.* Between 800,000 and 900,000 kw-hours per month.

16. The number of power units in each station and the output of each unit?

A. Two. 550-kw generators. *B.* Two. 850-kw each. *C.* Two. 300-kw generators. *D.* One. Output as above. *E.* 5 units, 500 kw each.

17. The number and type of boilers in each station and the horse-power rating of each?

A. Eight horizontal return fire tube cylindrical of 125 hp each. *B.* Ten steel return tubular boilers, 125 hp nominal each. *C.* Six horizontal return fire tube. 125 hp. *D.* One. Climax. 300 hp.

18. The number of boilers in use during ordinary traffic?

A. Four to six. *B.* Four. *C.* Two. During winter months a third boiler is used for heating New York division coaches. *D.* One. *E.* Eleven.

19. What is the fuel used?

A. Sparks collected from extension fronts of locomotives. *B.* Locomotive sparks. *C.* Sparks collected from smoke fronts of locomotives in round houses. *D.* Bituminous coal. *E.* Cumberland coal run of mine. Bituminous.

20. Give the weight of fuel consumed per kw-hour produced at the switchboard?

A. 6 lbs. when clean. *B.* 7 to 8 lbs. per kw-hour when clean. *D.* Thermal units: Quarter load, 2.7; half load, 3.75; full load, 4.8. *E.* 4.53 lbs.

21. Number of pounds of water evaporated per pound of fuel?

A. About 4½. Equivalent for coal, 9 lbs. *B.* About 4.9. Equivalent for coal, 9.8 lbs. *C.* 4.9. Equivalent for coal, 9.8 lbs. *D.* 6.14 to 9.42 lbs. *E.* Average between 9 and 10 lbs.

22. Do you use forced draft?

A. "Argand" steam blowers in ash-pit fronts to ignite sparks, and for use under abnormal loads. *B.* Yes. *C.* Yes; to ignite sparks, and during excessive loads. *D.* No. *E.* Induced.

23. What steam pressure is used?

A. 120 lbs. per sq. in. *B.* 120 lbs. *C.* 100 lbs. to 120 lbs. *D.* 130 lbs. *E.* 125 lbs.

24. Give dimensions of smoke-stack?

A. Height above grates, 112 ft.; diameter of bore, 6 ft. 6 ins. *B.* 7½-ft. flue. 123 ft. high, above grates. *C.* Height above grates 113 ft.; diameter of bore, 6 ft. 6 ins. *D.* 40 ins. diameter; height 70 ft. above grate. *E.* 8 ft. diameter projecting only above roof.

25. What is the general plan of piping used to secure dry steam? Percentage of moisture in steam?

A. Copper bends rise from boilers into 16-in wrought iron header in boiler room. Engine connections made of wrought iron bends tapped into risers from header. Percentage moisture in steam is 1 per cent and less. *B.* Boilers below engines. Pipes rise from boilers to main header and fall to engines. *C.* Copper bends rise from boilers into 16-in. wrought iron header in boiler room. Engine connections made of wrought iron bends tapped into steam header. Percentage moisture in steam, 1 per cent and less. *D.* Straight line from boiler to engine, with steam trap attached leg of same. 3.4 per cent to 4.7 per cent. *E.* Separators, Lox and Holly drips.

26. Is the condensation in piping returned to the boilers?

A. Yes. *B.* Yes. *C.* Yes. *D.* No. *E.* Yes.

27. If so, how?

A. By Holly gravity return system. *B.* Holly gravity return system. *C.* By Holly gravity return system. *E.* Holly and Lox drips.

28. How is the feed-water heated?

A. By exhaust from engines in two horizontal Berryman heaters, and by condenser and feed pump exhausts in one auxiliary vertical Berryman heater in boiler room. *B.* By exhaust from engines through primary and auxiliary heaters of Berryman type. *C.* By exhaust steam from engines passing through Berryman horizontal heater. *D.* Vertical type. Goubert feed-water heater. Exhaust steam from engine circulating around water tubes. *E.* Warren Webster feed-water heater.

29. What is the temperature of the feed-water upon entering the boilers?

A. 180 degs. to 212 degs. F. *B.* About 200 degs. F. *C.* 190 degs. to 212 degs. F. *D.* 194 degs. to 200 degs. F. *E.* About 210 degs. F.

30. Describe make and type of engines used in each station?

A. Engines tandem-compound condensing of "Greene Improved" type. *B.* 28 ins. and 48-in. x 48-in. Greene cross-compound engines. *C.* Greene improved; simple, non-condensing. *D.* Westinghouse, Kodak type, direct-connected. *E.* One Greene, four Allis-Corliss. All tandem compound.

31. Give diameter of cylinders, length of stroke, revolutions per minute, length and diameter of shaft, and weight and diameter of fly-wheel?

A. Horse-power cylinder, diameter, 20 ins.; L. P. cylinder, diameter, 38 ins.; stroke, 48 ins.; revolutions per minute, 106; length of shaft, about 10 ft. between bearings; diameter of shaft at center, 18 ins.; weight of fly-wheel, 60,000 lbs.; diameter of fly-wheel, 18 ft. *B.* 28 ins. and 48 ins. diameter, 48-in. stroke, 100 r. p. m.; shaft 18 ins. x 2.16 ft.; fly-wheel, 55 tons; diameter, 18 ft. *C.* Diameter, cylinder, 26 ins.; length stroke, 48 ins.; revolutions per minute, 100; length shaft between journals, about 9 ft. 6 ins.; diameter of shaft, 16 ins.; weight of fly-wheel, 45,000 lbs.; diameter of fly-wheel, 18 ft. *D.* High, 18 ins.; low, 30 ins.; stroke, 16 ins.; revolutions per minute, 250; diameter of shaft, 8 ins.; weight of fly-wheel, 3000 x 6700 lbs.; diameter, 13½ ft. *E.* Allis, 24 ins. x 40 ins. x 42 ins.; 100 revolutions; length of shaft, 15 ft. 6 ins.; diameter of shaft, 16 ins.; weight of fly-wheel, about 18 tons; diameter of fly-wheel, 18 ft.

32. If condensing, describe the type of condensers used?

A. "Deane" jet condenser, jet condensing chamber mounted directly on water end of single steam circulating pump; no separate air pump. *B.* Deane independent horizontal condensers. *D.* Non-condensing. *E.* Don't condense.

33. Are the generators direct-connected or belted?

A. Direct-connected. *B.* Direct-connected. *C.* Direct-connected. *D.* Direct-connected. *E.* Direct.

34. How many of the stations generate direct current?

A. One. *C.* One. *D.* One.

35. What is the voltage at the station at full load? At no load?

A. Full load, 700 volts; no load, 650 volts. *B.* 700-650. *C.* 550 volts at full load, 500 volts at half load. *D.* 550 volts; 500 volts. *E.* 750 volts at all times.

36. Are so-called "boosters," or any apparatus for raising the voltage of a particular feeder or feeders used in the station?

A. No. *B.* No. *C.* No. *D.* No. *E.* Yes.

37. If so, how are they driven?

E. Motor-driven.

38. What apparatus is used to protect the generators from lightning discharges?

A. Shunt arresters of type G. E. M. D. placed in station, and arresters of type G. E. M. D. on pole line, one opposite station. *B.* G. E. Shunt lightning arresters. *C.* Arresters in station of type G. E. M. D. and four arresters on pole line of type G. E. M. D. *D.* Lightning arresters and tank arrester. *E.* General electric lightning arresters.

39. Has any damage from lightning occurred in those stations operating a third rail only, where no overhead conductors are used?

A. No. *B.* No.

40. Are storage batteries used?

A. No. *B.* Yes, for lighting only. *C.* For lighting only. *D.* No. *E.* No.

41. If so, describe the apparatus used to charge them?

B. Motor generator transforming direct current from 650 volts to 150 volts. Also directly through a rheostat in small plants. *C.* Motor generator of 25-kw capacity. Direct-connected. *D.* Not used.

42. Is any of the power of the station used for other purposes, such as supplying electric lights at the depots along the line or driving stationary motors for ventilation, heating or other power purposes?

A. One circuit of series arc lamps in power station, and incandescent lamps in car house, power station, and one station on line. *B.* Yes. To light passenger stations, freight houses, etc., and for lighting and heating cars. *C.* Yes. For lighting the Stamford passenger station and the freight houses; also during winter months one boiler is used for heating New York division coaches. *D.* Used for electric lights at power house and at Mt. Holly station. *E.* Yes.

CONDUCTORS

1.—The Positive Conductors

43. Give the position of the working conductor relative to the track?

A. Pemberton section, overhead. Braintree section, on blocks between rails of tracks. Overhead span construction at stations. *B.* In the center of the track on the ties. *C.* Overhead not divided into insulated sections *D.* Overhead. *E.* Overhead.

44. Of what metal does it consist?

A. Pemberton section, copper. Braintree section, steel. *B.* Steel, 100 lbs. per yard. *C.* Round, No. 000 and No. 0000, B. & S. copper wire. *D.* Copper. *E.* Iron with copper feeders.

45. If overhead, how is it supported and insulated?

A. Pemberton section, supported by mechanical clip hangers mounted on angle iron cross-arms bolted to poles between tracks. On steel trusses in yards where poles are outside of roadway. *C.* On brackets made up with flexible span. *D.* Cross suspension. *E.* Supported by catinaries attached to vertical columns. Cone insulators used.

46. If overhead, describe the poles used, their spacing, and the method of placing in the ground?

A. Poles of square Georgia pine, 30 ft. long, 12-in. x 14-in. butt, 10-in. x 12-in. top. Set 90 ft. apart on straight and 60 ft. to 90 ft. on curved line. Set in boxes 6 ft. deep, 3 ft. x 4 ft. across, filled with cement concrete. *C.* Poles of Georgia pine, machined octagonal, 10-in. butt, 8-in. top, 30 ft. long, set in ground; where ground is soft, set in barrels filled with stone, or grouted with cement concrete. *D.* Chestnut poles, 12-in. butt, 8-in. top, set 100 ft. apart and sufficiently high to give trolley wire a clearance of 22 ft. Poles as described in article 68. Concreted ground.

47. What means are used for protecting the line from lightning?

A. Lightning arresters on poles of type G. E. M. D. *C.* Four-pole lightning arresters. *D.* Lightning arresters. *E.* Lightning arresters at half-mile intervals.

48. If the working conductor is not overhead, give its position relative to the service rails?

A. On Braintree section, third rail of A section, 93 and 100 lbs. per yard is laid on creosoted wooden blocks between service rails. Blocks spiked to ties. Rails not fastened. *B.* Midway between the rails and projecting 1 in. above them.

49. Give the shape of its cross section and its area in square inches?

A. A shape, cross section of 9.3 and 10 sq. ins. *B.* Inverted V with flat top 10 sq. ins. area.

50. If of any other metal, give its conductivity as compared with copper?

A. Steel, 56 to 80 per cent carbon; conductivity, 1.8 to 1.9 that of copper. *B.* About 1.8 of that of copper of same area.

51. State how it is supported and insulated?

A. Laid without fastening on creosoted wooden blocks spiked to ties between service rails. *B.* Supported and insulated upon creosoted hardwood blocks fastened to the ties.

52. Describe the special arrangements used at grade crossings, switch-points, cross-overs, etc.

A. At grade crossings gaps in rail are bridged by bare copper cable (2,800,000 cm to each rail), laid in residuum compound-filled creosoted wood tubes laid in boxes filled with compound. Same done at switch-points. Overhead cable and trolley used at stations. *B.* The conductor rail ends at each side of a grade crossing, switch, and heavy copper conductors connect its ends, passing underground in an insulated wooden conduit.

53. Is it divided into sections automatically connected to the supply current by the motor car, or is it continuous throughout its length?

A. No. *B.* Continuous.

54. If sectional, what are the lengths of the sections?

55. Describe the automatic switches and the methods of operating them?

56. What is the method of bonding the conductor rail? Describe the bonds?

A. Bonds of tinned copper 4 ins. x 12 ins. x ⅛ in. inserted on each flange of A-shaped rail between underside of flange and splice plates. Splice plates, 4 ins. x 12 ins. x ⅝ in. Contact surface of bonds, 82 sq. ins. *B.* The bonds consist of two rectangular copper washers, tinned, 4 ins. wide by 12 ins. long, held by similar iron washers ⅜ in. thick underneath and 16 bolts. Contact surface, 82 sq. ins. *E.* Chicago bond.

57. Are these bonds equal in conductivity to the rail, or is there a loss in the joints?

A. Yes. No loss in joints. *B.* Yes, there is practically no loss. *E.* Equal.

58. State the leakage per mile in amperes in wet and dry weather?

A. About 4 amps. per mile in wet, and ½ amp. per mile in dry weather. *B.* One-half amp. per mile in dry weather; 4 amps. in wet. *C.* When new and in damp weather, 1-1000 amp. *E.* One-half amp. per mile.

59. If feeders are used, give their position and the metal of which they are made?

A. Third rail on Braintree section fed from the power station at Nantasket Junction (1 mile) by overhead bare copper cables of 800,000 and 500,000 cm area, supplemented by feeder made up of old rail, laid at side of roadway. *C.* None used. *C.* Bare copper feeders on glass insulators on cross-arms. Feeders of 300,000 cm and 500,000 cm area, and of 0000 bare soft-drawn copper wire. *E.* Copper laid on top of conductor.

60. If of steel and near the track, how are they supported and insulated?

A. 2.60 lb. steel rails bolted with flanges together and set on posts about 24 ins. high set every 10 ft. on side of roadway. Conductor boxed over with creosoted planks.

61. State where they tap the working conductor?

A. At Nantasket Junction, 1 mile from power station. *C.* About every 1000 ft one 500,000-cm feeder running 6 miles to feed grade.

62. What is the resistance per mile of the working conductor?

A. 0.044 ohms. *B.* 0.042 ohms.

2.—The Negative or Return Conductors.

63. Does the ground form an appreciable aid to the return circuit?

A. No. *B.* No. *C.* No. *D.* Yes. *E.* No.

64. Describe the bonds used and the method of bonding the service rails?

A. Bonds of leaf copper, made up with heads of drop-forged copper, expanded into holes in rail flange by taper pins driven into bond heads from above. Bonds inserted in holes in flange from below. Four bonds per joint. 24½ ins. long; 210½ ins. long. Total cross-section, 1,100,000 cir. mil. Also, older form of bond made up of No. 0000 copper cable (two per joint), with ⅝-in.

heads riveted into rail flanges from beneath. *B.* Bonds are four in number, of leaf copper, flexible and attached to the base of rails by lugs on bonds passing through holes in base. Lugs are then expanded in the hole by steel pins passing through a smaller hole in lugs. *C.* Rail joints bonded with two leaf copper bonds 4½ ins. long and two leaf copper bonds 10½ ins. long, made with 1-in. heads expanded into holes in base of rail by wedge-shaped or tapered steel plugs driven from above. Bonds underneath rail. Total cross section, 1,100,000 cir. mil. *D.* No. 0000 copper bonds. No. 00 copper cross bonds. *E.* Chicago bond, two No. 0000.

65. Are these bonds equal in carrying capacity to the rails they connect?

A. Yes. *B.* Yes. *C.* Yes. *D.* No.

66. What is the total cross section in square inches of return conductors?

A. Pemberton section, 30.4 sq. ins; Braintree section, 40.0 sq. ins. *B.* Single track about 14 sq. ins.; double, 28. *C.* 14.4 to 14.8 sq. ins. *D.* Outside of the rail, ¼ in. sq.

67. Are any special negative conductors used to supplement the service rails?

A. No. *B.* No. *C.* No. *D.* Yes.

68. If so, describe them?

D. One No. 0 return wire and cross-bond. *E.* 1-1,000,000 cir. mil copper.

69. What is the maximum drop in line voltage at the most distant point from the power station during maximum load?

A. Momentary drop of 350 volts at Braintree. *B.* About 50 per cent. *D.* 55 per cent.

70. What is the proportion of drop in the positive and negative during the above conditions?

A. Drop in negative about 50 per cent of drop in positive on Braintree section. *B.* Two-thirds in positive, one-third in negative.

71. What is the average efficiency of the line?

A. Average efficiency during maximum loads of Braintree section, 70 per cent. Average efficiency during the maximum loads of Pemberton section, 75 per cent. *B.* About 75 per cent. *D.* Good.

ROLLING STOCK

72. Are electric locomotives or passenger-carrying motor cars used? Are trailers used? If so, how many?

A. Passenger-carrying motors. Yes. One to four 12-ton open trailers and one to three 27-ton coaches, and one to three 30-ton coaches. *B.* Passenger-carrying motor cars and trailers. From one to four. *C.* Passenger and baggage carrying combination cars. Trailers are used. One and two. *D.* Passenger-carrying motor cars. Trailers are used. One or two. *E.* Locomotives, three.

73. How many motor cars or locomotives are in use? Give their weight empty, and the number of passengers they seat?

A. Regular service between Braintree and Pemberton, six open 33-ton motors; Braintree and Cohasset, two 48½-ton four-motor combination cars. Open 33-ton motors seat ninety-six passengers; four-motor combination cars seat forty-five to fifty passengers. *B.* Four at one time. Open motors weigh 66,350 lbs. Seat ninety-six. Closed motors weigh 81,000 lbs. Seat about seventy. *C.* Two. Weight, total, 50,000 lbs. Seating capacity, forty. *D.* Three. Weight, 52,000 lbs. Fifty passengers. *E.* Three. Weight 97 tons each.

74. Give the rated horse-power of the locomotives or motor cars?

A. Two motor equipments (open cars), 350 hp; four motor equipments (combination car), 700 hp. *B.* 350 hp. *C.* Rated horse-power, 320. *D.* 200 hp. *E.* 1000 hp each.

75. What is the general arrangement of the mechanism? i. e., the type and number of motors per car. The power of each motor, its revolutions per minute at normal speed, and its weight?

A. Two "G. E. 55" motors on one truck of two motor cars, and on each truck of four motor cars. Rating of G. E. 55 motors, 175 hp at 550 volts. Revolutions per minute, 700 to 1000. *B.* Two motors per car. G. E. 55. Both on one truck. Rated 175 hp. Each weighs 5000 lbs. and runs about 1000 r. p. m. at normal speed. *C.* Two motors on one truck, of type G. E. 55. Each motor rated at 160 hp at 500 volts. Normal speed, 760 r. p. m. Weight with gears and gear covers, 5415 lbs. *D.* Westinghouse special. One car has four 50-hp motors, one on each axle, and two have two 100-hp motors each, one on each truck. 1000 r. p. m. at speed. Weight, about 3500 lbs. *E.* Four motors per locomotive, 250 hp each.

76. The number of trucks and the number and diameter of wheels under the car and the number of wheels used for traction?

A. Two. Eight 36-ft. wheels. Two motor equipment four wheels, four motor equipment eight wheels. *B.* Two trucks. Eight 37-in. wheels, four of which are used for traction. *C.* Two trucks. Diameter of wheels, 36 ins. Number of driving axles, 2; number of driving wheels, 4. *D.* Two trucks. Eight 36-in. wheels. Car with four 50-hp. motors uses every wheel. Other use one pair in each truck. *E.* Two trucks. Diameter of wheels, 62 ins. All wheels used for traction.

77. Are the motor armatures mounted directly upon or geared to the axles?

A. Single reduction gearing. *B.* Geared. *C.* Geared. *D.* Geared to the axles. *E.* Mounted on axles.

78. Give diameter of driving axles?

A. 6½ ins. *B.* Gear fittings 8 ins. diameter; wheel fittings and motor journals, 6½ ins.; journals, 5½ ins. x 9 ins. *C.* Diameter of driving axles, 6½ ins. *D.* 5¼ ins. *E.* 8 ins.

79. Give total weight on driving wheels, i. e., weights available for traction?

A. Two motor equipments, 38,500 lbs.; four motor equipments, 97,000 lbs. *B.* 39,600-lb. open cars; 47,000-lb. closed cars. *C.* 36,000 lbs. *D.* About 52,000 lbs. *E.* 97 tons.

80. Describe the winding of the motors?

A. Series wound. Armatures, 1 turn; field spools, large, two of 62 turns each; small, two of 29 turns each. *B.* Four-pole series drum winding. *C.* Motor series wound four field coils in series. Armature, 1 turn; large field spools, 62 turns each; small field spools, 29 turns each. *D.* Westinghouse special.

81. Are the motors supported in any manner by the truck frames?

A. No. *B.* No. *C.* Motors are supported on spring nose plates, resting on independent equalizer bars, spring suspended from motor frames beneath axle journals. *D.* Yes. *E.* Yes.

82. Describe the motor suspension?

A. Motors are supported on spring nose plates resting on independent equalizer bar springs suspended from the motor castings under the axle journals. (See Fig. 14.) *B.* Two heavy bars supported by links at each end attached to motor frame at axles, extending from one axle to the other. Back of motors rest on these bars. *D.* The back of the motor is supported by the cross frame of the truck, and the front of the motor by the axles. *E.* Springs and cushions.

83. Are any special facilities provided for in the design of the motors or trucks for rapid exchanging of parts, such as replacing an armature or other repair work?

A. Truck frame may be lifted clear of the motors, wheels and motor equalizer bars; or motors may be lifted out of the truck after rolling out from under cars. *B.* Truck frame can be lifted off, leaving wheels, axles and motors with the suspension free to be exchanged for others or repaired. *C.* Body of truck may be lifted off, leaving motors on independent equalizer. Motor with its pair of wheels may be readily detached, or motor lifted out independently. *D.* Casings are divided in two parts, one part lowering to allow armature to be taken out. *E.* No.

84. What provision is made for ventilating the motors?

A. Gauze covers are in trial. In hot weather motors are run with covers removed. *B.* Three hand-holes with covers of wire netting. Also large cover over commutator with netting. *C.* Motors are run with screen ventilating covers, or with covers removed. *D.* Usual ventilating holes. *E.* Nothing unusual.

85. What is the system of control?

A. Series parallel. *B.* Series parallel. *C.* Series parallel. D. Westinghouse special controllers. *E.* Series parallel.

86. Describe the controlling apparatus?

A. A series parallel controller of type G. E. L. 2 is placed on each platform, and connected with motors and resistance boxes under cars. *B.* G. E. L. 2 controller. *C.* A series parallel controller of type G. E. L. 2 on each end of car, in vestibule. *D.* As above. *E.* Contacts mounted on revolving cylinder; blow-outs (magnetic) on side.

87. What is the form and material of resistance?

A. Resistance boxes built up of wrought-iron tape stampings of type P. R., G. E. Co. are used. *B.* Packed iron ribbon. G. E., P. R. resistance. *C.* Resistance boxes of iron tape; type P. R., G. E. Co. *D.* Diverters. *E.* German silver strip.

88. What system of braking power is used? Is it satisfactory?

A. Westinghouse automatic air, using Christensen motor-driven compressor and compressor controller. It is satisfactory. *B.* Westinghouse automatic air. Independent motor compressor. Yes. *C.* Westinghouse brake cylinder and triple valve; Christensen engineer's valves; "automatic air." *D.* Westinghouse air. Yes. *E.* Westinghouse air-brake system. Satisfactory.

89. Describe the alarm signals used—whistles or bells, and how operated?

A. Gongs of standard locomotive bell weight are attached to hand rails on ends of cars, and three-note chime whistles blown by air. *B.* Large 18-in. gong, worked by the foot. Large chime whistle, blown with 80 to 90 lbs. compressed air. *C.* Gongs of standard locomotive bell weight, and air whistles of three-note chime. *D.* Engine bell on top of car. *E.* Whistles operated pneumatically. Bells used, pulled by hand.

90. Describe the current-collecting devices used on motor cars?

A. All motor cars are fitted each with two overhead trolleys and two third-rail shoes. Trolley poles of tapered steel tube are held up by spring tension of 28 to 30 lbs. Wheel is 5 ins. diameter, made up with composition body and steel flanges, giving square groove and flat tread. Shoes are of cast iron, supported by cast-iron links under each king-pin, giving a contact surface of 14 ins. x 2½ ins. and resting on rail of their own weight. *B.* Cast-iron shoes about 14 ins. long and weigh about 28 lbs., supported by links from an insulated support. Two per car. *C.* 15-ft. steel trolley arms carrying special 5-in. wheel made up with composition hub and steel flange: groove wide and straight; tread square. *D.* Trolley wheel and carbon brushes. *E.* Brass shoes, two in series, about 24 ins. long and 5 ins. wide, pointed at either end.

91. Describe the method of heating and lighting?

A. Heating during the months operating this system is unnecessary. All cars are lighted by 16-cp incandescent railway lamps, connected up in series groups of five or six lamps. *B.* Electric heaters of resistance wire embedded in enamel. Lights are 16-cp incandescent, wired, 6-in. series, twenty-four to thirty per car. *C.* Heating by "National" electric heaters. Lighting by 16-cp incandescent lamps. *D.* Electrical. *E.* No heat. Light taken from motor circuit.

92. Are any special devices used on motor cars for the removal of snow from the track, or snow and sleet from the conductor rail or trolley wire?

A. No. *B.* Snow plows under car platforms with rattan brushes on lower edge. Also steel brushes on conductor rail. *C.* No. *D.* Pilot of motor car and sleet wheel on wire. *E.* No.

OPERATION

93. Give the number and style of cars and total weight of each train in ordinary service?

A. Pemberton section, 33-ton, 16-bench, open 2-motor cars in regular half-hour service. Average weight of train of one open motor car and two open trailers, 60 tons. Braintree section, half-hour service, same as above. Heavy work, two trains of one 48½-ton motor car and two or three 30-ton coaches each. Average weight, 130 tons. *B.* Ordinary service, motor car and one trailer. Summer train weighs about 46 tons. Winter train, 70 tons. *C.* One motor car of 50,000 lbs. weight, one or two coaches of 29,000 lbs. weight each, one or two open trailers seating seventy passengers, of about 27,000 lbs. weight. *D.* Three motor cars. From 52,000 to 156,000 lbs., about. *E.* Ordinary freight train weighs about 1400 tons Standard car.

94. Give the time schedule and distance each train is run?

A. Pemberton to Braintree, 15.7 miles, schedule time 51 min.; Cohasset to

Braintree, 11.5 miles, schedule time, 34 min. *B.* Hartford to Bristol, 18 miles in 40 min., five stops. Berlin to New Britain, 3 miles, 7 min., no stops. *C.* Distance, 7.66 miles; schedule time, 17 to 20 min. *D.* About 20 min; 7.1 miles. *E.* No schedule. Trains run 4 miles.

95. The normal speed on the level and on grades?

A. 60-ton trains on level, about 40 miles per hour; 60-ton trains on grades, from 30 miles per hour up; 130-ton trains on level, 35 miles per hour; 130-ton trains on grades, 25 miles per hour up. *B.* On level, 35 to 40 miles per hour. Down grade, 50 to 60. Up, 15 to 20. *C.* 3 miles per hour on level; 25 to 30 per hour on grades. *D.* About 21 miles per hour. *E.* Speed on level, 15 miles per hour; on grade, 10.

96. The maximum number of motor cars or trains which can be run at one time?

A. Twelve trains of varying weight. *B.* About six ordinary trains. *C.* Two. *D.* Three. *E.* One.

97. The average amount of power consumed by each train at average speed, in kilowatts measured on the car?

A. 60-ton train, 75 kw-hours; 130-ton train, 150 kw-hours. *B.* 75 kw. *C.* Average 70 kw. *E.* No recording device.

98. The number of kw-hours per train mile measured on the car?

A. 60-ton train, 3.0 kw-hours; 130-ton train, 5.2 kw-hours. *B.* About 2½ kw-hours for the ordinary train. *C.* Stamford to New Canaan, 2.9; New Canaan to Stamford, 1.25. Average, 2.10 kw-hours. *E.* 14 approximate.

99. Watt-hours per ton mile?

A. 30-ton train, 50 watt-hours; 130-ton train, 40 kw-hours. *B.* 50 to 75. *C.* Stamford to New Canaan, 80; New Canaan to Stamford, 39. Average, 59.5 kw-hours. *E.* 36.6.

100. Give total cost of power per kw-hour?

A. 0.007575. *B.* 1 cent. *C.* $0.0119. *E.* Between 6 and 7 mills.

101. Give cost of fuel only per kw-hour?

A. 0.00260. *B.* $0.004. *C.* 0.00208. *E.* 2¾ mills.

102. Give cost of water only per kw-hour?

A. 0.000382. *B.* $0.0006. *C.* 0.00058. *E.* 1-3 mills.

103. Cost of labor at power station per kw-hour?

A. 0.00422. *B.* $0.0043. *C.* 0.00565. *E.* 3 mills.

104. Give cost of maintenance at power station per kw-hour?

A. 0.000373. *B.* $0.0015. *C.* 0.00290. *E.* 3-10 mill.

105. Cost of maintenance of motor cars per car mile?

B. 0.018. *E.* $0.08 approximate.

106. Cost of labor in operation of trains per mile?

A. 0.0728. *B.* 0.034. *C.* 0.0593.

107. How many hours per day is each power station in operation?

A. 18. *B.* 18 hours. *C.* 18 to 18½. *E.* 24 hours.

108. How many men are required to operate each station?

A. 8. *B.* 9. *C.* 6. *E.* 28.

109. Number of shifts?

A. 2. *B.* 2 (Firemen 3). *C.* 2. *E.* 2.

110. Number of men in each shift?

A. 4. *B.* 4. *C.* Four on day shift, two on night shift. *E.* Sixteen day, twelve night.

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

UNITED STATES PATENTS ISSUED AUG. 28, 1900

656,635. Electric Motor Suspension; G. Gibbs, Philadelphia, Pa. App. filed Feb. 28, 1898. The motor is hinged upon the axle, the field magnet being arranged on one side thereof, and an extension from the frame projecting from the other side. A cradle supports the motor, a spring being inserted between the cradle and the projection.

656,636. Electric Motor Suspension; G. Gibbs, Philadelphia, Pa. App. filed May 11, 1900. A modification of the preceding patent.

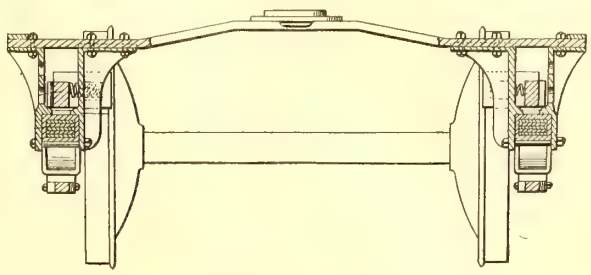
656,753. Railway; J. Sparrow, Reading, England. App. filed July 11, 1899. According to this invention cars can be moved from a double track onto a single track without the use of movable switches, the invention consisting in a special construction of rail flanges and shoulders.

656,878. Car truck; J. A. Brill, Philadelphia, Pa. App. filed May 15, 1899. Consists in a construction whereby the usual bolster-transoms which extend between the side frames are dispensed with, and said transoms formed by inwardly extending brackets either secured to or formed integrally with the side frame.

656,885. Radial Car Truck; J. P. Faye, Binghamton, N. Y. App. filed March 17, 1898. The axles and wheels are mounted in frames, which are connected together by toggle levers.

656,900. Car Truck; J. L. Levy, New York, N. Y. App. filed Sept. 14, 1897. This construction provides for extending the bolster suspension or spring base closely adjacent to the axle-box pedestals, in order to give a greater spring base for the support of the car body on the truck.

656,935. Fare Register; W. L. Brownell, Elizabeth, N. J. App. filed Nov. 12, 1897. The invention consists in an arrangement whereby the bell-hammer is protected against any disturbance whatever until after the return stroke of the pulling-pawl is fully completed, the bell hammer receiving the necessary impulse to ring the bell while the head of the pawl is in the act of dropping behind a newly advanced ratchet-tooth preparatory to the next registration, the object and effect being to render it both theoretically and practically impossible to ring the bell more than once for each registration of a fare.



PATENT NO. 656,878

656,986. Construction of Railroad Tracks; G. Lindenthal, New York, N. Y. App. filed July 20, 1899. Longitudinal sleepers for railroad tracks, consisting of successive sections and of splice plates joining the sections longitudinally, and having ends bent downward and transversely to the line of the longitudinal sleepers.

ENGINEERING SOCIETIES

CENTRAL RAILWAY CLUB.—The next regular meeting of this club will be held on Friday, Sept. 14, 1900, at 10 a. m., at the Hotel Iroquois, Buffalo, N. Y. The executive committee will meet at 9 a. m. Prof. Gaetano Lanza, of the Massachusetts Institute of Technology, will read a paper upon "Efficiency Tests of Locomotives." The following reports by special committees, submitted at the May meeting, will be discussed: "Best form of construction, and methods of ventilating, heating and general equipment of roundhouses." Committee: W. H. Marshall, chairman; George W. West, C. H. Potts. "Standard box cars; technical details of construction along the lines recommended by the committee on typical dimensions whose report was presented at the January meeting." Committee, L. T. Canfield, H. F. Ball.

PERSONAL MENTION

MR. H. S. COOPER has resigned as general manager of the Ithaca, N. Y., Street Railway, to take effect Oct. 1. Mr. Cooper was born in Isle of Wight, England, in 1856, and came to America in 1865. He was educated at Farum School, Beverly, N. J., and worked as clerk and salesman in Philadelphia from 1870 to 1876. In the latter year he engaged in the manufacture of agricultural machinery at Raleigh, N. C., and Jacksonville, Fla., and in connection with this had charge of the electrical work on two lines of steamers on the St. Johns River, and of considerable work in the two lighting stations in Jacksonville at that time. In 1893 he accepted the managership of the Schenectady properties of the Electrical Development Company, later the Schenectady Railway Company, which position he resigned in 1899.

NEWS NOTES

(Readers will confer a favor by sending us news for this department.)

MONTGOMERY, ALA.—The street car ordinance providing for the separation of the white and black passengers on street cars has caused an eruption here. The negroes have held mass meetings and have declared a boycott on the company.

SELMA, ALA.—W. R. Hall has been engaged to superintend the conversion of the Selma Street & Suburban Railway from a mule to an electric line. Mr. Hall is now looking over the routes and preparing an estimate of the cost of construction. Mr. Hall succeeds Mr. Marion as superintendent of the company, and the latter will go with the Birmingham, Selma & New Orleans Railroad, which owns the Selma property.

COLORADO SPRINGS, COL.—The Colorado Springs Rapid Transit Railway Company has entered into a contract with the Colorado Springs Electric Company for obtaining power to operate its lines from the plant of the latter company for a period of five years.

NEW HAVEN, CONN.—The Fairhaven & Westville Railroad Company has reduced the fare to East Haven from 10 cents to 5 cents.

NEW HAVEN, CONN.—It is understood that the United Gas Improvement Company, of Philadelphia and New York, will apply next year for a franchise to extend the electric railway lines now terminating at Woodmont to Savin Rock and New Haven via either Davenport Avenue or Washington Street.

WASHINGTON, D. C.—The Washington & Gettysburg Electric Railroad Company, which was granted a franchise last September by the Board of Aldermen, of Frederick, Md., for the use of the streets of Frederick, has secured an extension of time in which to begin work on the road until April 30, 1901.

SAVANNAH, GA.—The Savannah, Thunderbolt & Isle of Hope Railway Company has petitioned the Council for permission to make a number of minor changes in the operation of its lines, and for permission to double-track one line for a short distance.

CHICAGO, ILL.—The street railway companies operating here have been notified to have their cars equipped with vestibules by Nov. 1.

CHICAGO, ILL.—Two bills will be presented at the next session of the Legislature looking to the protection of the city's interests, whether the present system of surface terminals in the downtown district is maintained or a subway scheme substituted. In each bill provisions will be made for the eventual control of at least the tracks and right of way by the city. The Street Railway Commission all along has shown no disposition to favor the scheme of owning the rolling stock, because of the immense amount of detail involved. The Aldermen have taken the position that with the proprietorship of the rails the city could eventually lease them to the highest bidder and stipulates as one of the conditions that poor service would be due cause for the abandonment of the contract.

KOKOMO, IND.—The City Council of Elwood has passed an ordinance granting the Central Traction Company, of Indiana, a franchise for the construction of an electric railway from Elwood to Tipton. The franchise is to run for fifty years, and the company is required to have the road in operation by Jan. 1, 1902.

INDIANAPOLIS, IND.—The Indianapolis, Greenwood & Franklin Electric Railway and the Indianapolis & Greenfield Rapid Transit companies have signed the interurban franchises submitted to them by the Board of Works, granting the right to operate over the lines of the Indianapolis Street Railway Company.

PARIS, KY.—Local capitalists have just been granted a franchise for the construction of an electric railway here. The franchise stipulates that construction work be begun within a year, and that the road be completed within two years. H. A. Power, of Paris, is interested in the enterprise.

ROCKVILLE, MD.—At the special election held here a few days ago the action of the Town Council in granting a right of way over Montgomery Avenue to the Washington & Rockville Electric Railway Company, was upheld.

PALMER, MASS.—A collision occurred on the Palmer & Monson Street Railway Aug. 26. Several persons were slightly injured.

LEXINGTON, MASS.—The Lexington & Boston Street Railway Company has made application to the Council for franchises for four lines—two between the Lexington and Lincoln lines, and two between the Lexington and Woburn boundaries.

LEXINGTON, MASS.—Both the Boston & Concord Street Railway Company and the Lexington & Boston Street Railway Company have applications for a franchise pending here, and there are prospects of a bitter fight in Council.

GRAND RAPIDS, MICH.—The Council has passed an ordinance granting the Grand Rapids, Spring Lake & Grand Haven Electric Railway Company a twenty-year franchise for the construction of an electric railway through the city.

ST. LOUIS, MO.—An entire new equipment of cars was placed on the Northern Central division of the St. Louis Transit Company Aug. 30.

ST. LOUIS, MO.—The smoke-stack on the power house of the St. Louis Transit Company at Park and Vandeventer Avenues was blown down during a wind storm last week. It was 155 ft. high and the tallest in the city.

ST. LOUIS, MO.—The St. Louis County Court has granted the St. Louis, Fenton & Southwestern Railway Company an extension of time, till Jan. 1, to begin work on its proposed railway. This is the fourth time an extension of time has been granted.

SYRACUSE, N. Y.—The office of the Syracuse, Lakeside & Baldwinsville Electric Railway Company was entered by thieves Aug. 28 and robbed of $6000 in bonds and about $300 in cash.

SYRACUSE, N. Y.—The extension of the lines of the Syracuse & Suburban Railroad from Edwards Falls through Delphi to Reruyter is again being agitated.

BUFFALO, N. Y.—Local manufacturers and merchants are discussing a plan for having the street railway company transport freight from the receiving yard in the regular freight car direct to its destination. It is not known whether the plan has been laid before the street railway managers, but it is deemed impracticable. The franchise held by the company at the present time contains no provision covering the operation of freight cars as mentioned, and there would be considerable interference with general traffic. This the public would not tolerate.

BROOKLYN, N. Y.—The Brooklyn Rapid Transit Company is testing a new style car for the purpose of securing more seating capacity and at the same time have more standing room for heavy traffic. The cars are provided with individual seats, two abreast. They are arranged in such manner that they both slant backward toward the center, forming the letter V. Thus an aisle through the center allows much standing room and enables fifteen more passengers to be seated than on an ordinary car.

KINGSTON, N. Y.—The Peckham Manufacturing Company, of Kingston, was incorporated Aug. 29, with a capital of $500,000, to manufacture motors, car trucks and wheels. The company is to succeed to the business of the Peckham Motor, Truck & Wheel Company. The directors are: James H. Everett, V. B. Van Wagonen and Hewitt Boyce, of Kingston; Frank M. Jeffrey, George H. Bowers, William E. Davis and William Wampler, of New York City.

ASHEVILLE, N. C.—The Asheville & Weaverville Electric Railway & Power Company has been reorganized and the following new directors elected: Don. J. Barnes, John R. Baird, John M. Ramsey, O. D. Revell, of Asheville; J. B. Lotspeich, Edward F. Vandiver and W. E. Weaver, of Weaverville. The company has a thirty-year franchise for the construction of an electric railway in Asheville.

CLEVELAND, OHIO.—The Cleveland Electric Railway Company is preparing to introduce an ordinance in the City Council for a franchise for a single-track line from Tod and Fremont Streets, westerly on Fremont Street to Skinner Street, and northerly on Skinner Street to Tod Street. This will give the company a complete loop, and will enable cars to pass Harvard Grove Cemetery.

FREMONT, OHIO.—The Toledo, Fremont & Norwalk Electric Railway Company has secured a private right of way alongside of the Lake Shore and the W. & L. E. R. R. tracks from the west line of Monroeville to where its line crosses the Bellevue & Monroeville road, just east of Bellevue.

MARION, OHIO.—Right of way is now being secured for the construction of an electric railway from Marion to Prospect. The line is to extend through Green Camp. Among those interested in the new enterprise are: O. Wollenweber, D. R. Crissinger, French Crow, F. E. Guthery, J. W. Scott and Charles Hofstetter, of Marion.

COLUMBUS, OHIO.—The Columbus, London & Springfield Traction Company has been granted a franchise for the construction of its proposed line through West Jefferson.

NEWARK, OHIO.—The Newark & Granville Street Railway Company has been incorporated under the laws of Delaware to construct an electric railway in Newark, Ohio. The capital stock of the company is $300,000.

COLUMBUS, OHIO.—The Columbus & Johnstown Traction Company has made application to the Council for a franchise granting the company permission to enter Columbus over the lines of the Columbus Railway Company. The ordinance contains provisions for a 5-cent fare, six tickets for 25 cents and twenty-five tickets for $1. The term of the franchise is to be twenty-five years.

SPRINGFIELD, OHIO.—S. L. Nelson, of Wichita, Kan., formerly manager of the Springfield Street Railway, has brought suit against the latter company for $72,750, with interest, for services rendered in negotiating the purchase of certain Dayton property. The suit was originally entered against the American Railway Company, which owns the local lines, the latter suit being merely a method to overcome certain technicalities.

ZANESVILLE, OHIO.—The County Commissioners of Muskingum County have granted the Zanesville, Adamsville & Coshocton Electric Railway Company a franchise authorizing the construction of an electric railway over the county roads from Zanesville to Coshocton by way of Sonora, East Greenwood, Adamsville, Otsego, Plainfield and West Lafayette. The company binds itself to build the line within two years, and to leave the highways in good condition. The preliminary survey will be made as soon as the franchises through the villages and into the cities are granted.

LORAIN, OHIO.—A lively electric railway war is on in this city. Some time ago the Council granted the Cleveland, Elyria & Western Electric Railway Company a franchise for a single-track electric railway on West Erie Avenue. The Sandusky & Interurban Railway was also given a franchise for a double-track road on the same street. At a meeting of the companies and the city officials no agreement could be reached as to which company should build the tracks and own them, or which should occupy the center of the street. Last week the Sandusky Company constructed a double-track road from the center of the city to the town line. The Cleveland, Elyria & Western Electric Railway Company then laid a third track at the side of the street. The City Council is trying to find a way out of the dilemma.

PITTSBURGH, PA.—The Southern Traction Company is now being organized by Matthew K. McMullin, C. L. Magee, William Flinn, T. H. Given, J. D. Calley, James H. Reed and Joshua Rhodes, to take over the West End Traction Company, which was recently purchased by Mr. McMullin. It is said that the ultimate intention of the company is to merge all the lines south of the Monongahela River.

MEDIA, PA.—The Delaware County Commissioners have granted the Philadelphia & Delaware Trolley Company and the Prospect Street Railway, of Chester, permission to build two bridges on the Island Road, along the river front, between Philadelphia and Chester. One of the bridges will be erected over Darby Creek, in Tinicum Township, and one will span Crum Creek, in Ridley Township. The former will be 480 ft. long and the latter 100 ft. Each will be 26 ft. wide and both will be draws. They will cost about $60,000.

PORTSMOUTH, R. I.—The Gibbs Electric Signal Company has recently been organized under the laws of Rhode Island, with a capital of $50,000, for the purpose of manufacturing and selling automatic block signals, semaphore telephone signals and telephones. Harry T. Gibbs, general manager of the company, was formerly with the General Electric Company at Boston.

PROVIDENCE, R. I.—The United Traction & Electric Company has completed and placed in operation its new line between Providence and East Greenwich.

EL PASO, TEXAS.—Frederick E. Smith and Francis Seiberling, of Akron, Ohio, are in El Paso negotiating for the purchase of a franchise held by local parties for the construction of an electric railway here. Mr. Smith is vice-president of the Second National Bank, of Akron. He has announced that should the franchise be secured, a road will be in operation within a year.

EDITORIAL NOTICE.

The news issues of the Street Railway Journal are devoted primarily to the publication of street railway news and current happenings related to street railway interests. All information regarding changes of officers, new equipments, extensions, financial changes and new enterprises will be greatly appreciated for use in its columns.

All matter intended for publication must be received at our office not later than Wednesday morning of each week in order to secure insertion in the current issue.

Address all communications to

St. Louis Strike Called Off

In a mass meeting held Sept. 12 the striking street-car employees of the St. Louis Transit Company adopted resolutions calling off the strike and boycott against the company, and furthermore declared that any member of the union applying for work to the transit company would not endanger his membership thereby. The strike was ordered May 8, and called off on July 2. A week later it was reordered and the boycott imposed.

Electrical Equipment of New York Elevated Roads Delayed

The non-arrival of materials at expected times has seriously interfered with the work of electrically equipping the lines of the Manhattan Railway Company, and it is not known definitely when a trial of the system can be made on the Second Avenue line, on which work is most advanced. The work will be pushed with all possible speed, and a trial made at the earliest moment.

Yerkes Will Build a Road in London

A cablegram from London announced that Charles T. Yerkes, of Chicago, has purchased the franchises and all the rights of the Charing Cross, Euston & Hampstead Railroad, and that an American syndicate is to be formed to build a tunnel road under the streets from Charing Cross, in the heart of London, to Hampstead Heath, 4½ miles, and also an extension of 2 miles from Camden road to Kentish town. It is estimated that it will cost $12,000,000 to build the road. There is a large tract of land surrounding the suburban terminus of the new line, which has never been developed, and between this and the city is a high plateau over which no surface road has yet been built. The new road, as projected, is to pass under the plateau and emerge on the level track beyond, bringing this section within easy reach of the center of London. Electricity is to be used as motive power, and it is said that four tracks will be laid, two for express and two for local trains. Ten stations will be built. D. H. Louderbach, who was associated with Mr. Yerkes in his Chicago enterprises, and Henry C. Davis assisted Mr. Yerkes in completing the deal.

Street Railway Suggestions Officially Invited by the Chicago Street Railway Commission

The Chicago Street Railway Commission has made public a list of questions regarding the traction situation in that city on which it desires to receive suggestions from the residents of the city. This plan of submitting the questions to the public has previously been mentioned in the STREET RAILWAY JOURNAL, and in our last issue mention was made of the decision of the Commission to submit the question to the public. The people are asked:

"If public interests require the consolidation of all street railway lines under one management.

"If it should be the policy of the city to treat the street railway business as a monopoly.

"If franchises granted hereafter should contain a provision giving the city the right to take over the property at an appraised valuation.

"If they would prefer continuous car routes, passing through the heart of the city, in preference to the present system of downtown terminals.

"If they favor city ownership of tracks without city ownership of power plants or rolling stock and with city operation, or if they favor the policy of municipal operation either in the near future or ultimately.

"If the city, in granting franchises, should prescribe a minimum wage or a maximum working day for employees, and, if so, what they should be.

"If the city, in granting franchises, should require the traction companies to submit labor disputes to arbitration to avoid interruption in service.

"If they favor a system of subways or underground roads in the down-town district, making possible the removal of all cars from the surface."

The Commission requests that the views of the writer in each case be set forth in his own language, and be not confined to yes or no answers to the questions. It is not expected that every person will attempt to answer all the questions. The compilation, which will be made of the answers received, will be used both in measures recommended to the Council by the Commission and in bills which will be prepared for the Legislature. It is the intention to frame two measures for the General Assembly, one a grant of power relating to franchises and the other to the subway.

The Convention of the New York State Street Railway Association

As previously announced in this paper, the eighteenth annual meeting of the Street Railway Association of the State of New York will be held at Buffalo on Tuesday and Wednesday, Sept. 18 and 19. The meeting will be held at the Iroquois Hotel, and the following programme, which has been made up by President Rogers, has been decided upon:

TUESDAY, SEPT. 18

9:30 a. m.—Meeting of the Executive Committee.
10:30 a. m.—Meeting of the Association.
1. Call of the roll.
2. Approval of the minutes.
3. Address of the President.
4. Report of the Executive Committee.
5. Minutes of the special meeting of the Executive Committee.
6. Report of the Treasurer.
7. Reading of papers on practical street railway questions by well known gentlemen, names and subjects to be announced.
8. Discussion ensuing.
9. General business.
a. Appointment of Nominating Committee.
b. Nomination of officers.
c. Election of officers.
d. Selection of place of next meeting.

The entertainment of the attendants in the afternoon has been arranged for by the local committee, and includes a visit to the Pan-American Exposition grounds, by special invitation of William I. Buchanan, director general, and an inspection of the transforming storage battery stations of the Buffalo Railway Company. At 8 p. m. the annual banquet will be held at the Iroquois Hotel.

WEDNESDAY, SEPT. 19

9:30 a. m.—Second session of convention.
1. Unfinished business.
2. Reading of papers and discussion ensuing.
11:30 a. m.—Entertainment as arranged by local committee. This will include a trip by special cars of the International Traction Company, Buffalo and Lockport division, from the Iroquois Hotel, over the Buffalo division, Main Street line and the Buffalo and Lockport division, to North Tonawanda. The regular running time from Buffalo to North Tonawanda is at the rate of 50 miles per hour. At North Tonawanda an inspection will be made of a 35-ton electric locomotive drawing freight trains. Thence the party will proceed over the Niagara Falls division of the International Traction Company to Niagara Falls, where an inspection will be made of the power house (50,000 ehp) of the Niagara Falls Power Company, by special invitation of the power company. At this power house will be seen the transforming station from which high and low tension currents are transmitted for local manufacturing and smelting purposes, and 15,000 ehp at 11,000 volts, is transmitted to Buffalo. The party will then go by special cars across the upper steel arch bridge of the International Traction Company and over this company's Canadian division to visit Table Rock and the Dufferin Islands, by special invitation of James Wilson, superintendent of Queen Victoria Niagara Falls Park.

At 2 p. m. luncheon will be served at Dufferin Café.

At 3 p. m. the party will proceed by special cars over the Canadian division of the International Traction Company to Brock's Monument to visit the battlefield of Queenstown Heights, and will return to the American side over the International Traction Company's suspension bridge at Lewiston. The cars will then run over the Great Gorge route to Niagara Falls; thence over the Niagara Falls division of the International Traction Company to Buffalo, returning to Buffalo in time to take evening trains for New York and other eastern points. By special invitation of Godfrey Morgan, general manager of the Great Gorge route, a special searchlight expedition to Whirlpool Rapids has also been arranged for delegates and guests on this evening.

It is expected that some ten or twelve papers will be prepared and read, treating everyday, practical street railway subjects of vital importance and interest to street railway men generally. The exhibit feature promises to be larger and more pretentious than ever before, and the attendance of supply men much greater then at previous conventions. The following are the papers, together with their authors, definitely decided upon at this time:

"Power Distribution in Buffalo," by C. K. Marshall, electrical engineer of the Buffalo Railway Company.

"Rotary Transformers," by R. E. Danforth, superintendent of the Buffalo Railway Company.

"Storage Batteries," by Thomas Henning, superintendent of the power house, Buffalo Railway Company.

"Test of the Buffalo Railway Power House," by Prof. Norris, of Cornell University.

"Practical Experience in the Operation of Combined Public Franchises by One Company—Its Advantages to the Public and the Corporation," by C. E. Uebelacker, general manager of the Elmira Municipal Improvement Company.

"The Storage Battery—Its Use on Smaller Roads," by B. B. Nostrand, Jr., president Peekskill Electric Light & Power Company, Peekskill, N. Y.

It is also expected that papers will be prepared and read by representatives of the Metropolitan Street Railway Company, Brooklyn Rapid Transit Company, and by other prominent street railway gentlemen from various parts of the State, but the subjects of these papers have not yet been announced. The following topics for discussion or papers have, however, been decided upon:

Track Bonding.
The Third Rail.
The Repair Shop.
Induction Motors.
Care of Dynamos.
Car Mileage Record.
Indemnity Insurance.
Municipal Ownership.
"The Metallic Circuit."
Store Room Accounting.
The Three-Phase System.
Street Railways vs. State.
Loss of Current in Returns.
General Track Construction.
Employes' Benefit Associations.
"Receipts from Other Sources."
Transfers—Their Use and Abuse.
Street Railways vs. Automobiles.
Points on Overhead Construction.
Rotary Transformers. (Allotted.)
Long Distance Power Transmission.
Low Joints—How to Prevent Them.
Suggestions on Financial Organization.
Maintenance and Repair of Car Bodies.
Pleasure Resorts as Traffic Stimulators.
Signal Systems for Single Track Roads.
Air and Power Brakes for Electric Cars.
Reading and Club Rooms for Employees.
Care and Inspection of Wheels and Axles.
Power Distribution in Buffalo. (Allotted.)
Why Rates of Fare Should Not be Reduced.
The Selection and Management of Employees.
Care and Inspection of Motors and Equipment.
Amusements and Special Attractions for Parks.
The Power Station, from an Economic Standpoint.
How Can We Increase the Efficiency of Employees?
The Best Methods for the Prevention of Accidents.
The Relations of Municipalities vs. Street Railways.
Hints on Making Small Electric Railways Profitable.
Compressed and Liquid Air for Street Car Operation.
Storage Battery—Its Use on Small Roads. (Allotted.)
Mail, Freight and Express Service on Electric Railways.
Electrically Welded Joints in Actual Operation. (Allotted.)
Practical Experience with Double-Deck and Convertible Cars.
Removal of Snow and Ice—The Most Economical and Efficient Methods.
Single and Double Trucks—Their Relative Advantages and Disadvantages.
Practical Experience in the Operation of Combined Public Franchises by One Company—Its Advantages to the Public and the Corporation. (Allotted.)

Ample space has been arranged for at the Iroquois Hotel for exhibits, for the benefit of those manufacturers who desire to make them, and the president and executive committee of the association wish it generally understood that a most cordial invitation is tendered to all manufacturers of street railway apparatus and their representatives to attend the convention, whether they make exhibits or not.

In this connection it may not be amiss to refer to the admirable record made by the association during recent years. That this record, which has been followed by a greatly increased growth and influence, is due largely to the untiring efforts and ability of President Rogers and Secretary Robinson, is a fact generally recognized by those who have been closely following the history and acts of the association. It is a body which is exercising a great benefit to all the street railway companies of the State, and should have the cordial co-operation of all. This is shown not only by the admirable programmes which have been arranged for the different annual meetings, but by hard and persistent work during the year, in which the interests of the street railway companies are conserved in a way only possible by concerted action.

Meeting of the New England Street Railway Club

The New England Street Railway Club held its first regular meeting at the Pathfinder Meeting Rooms, 67 Federal Street, Boston, Wednesday evening, Sept. 5.

The meeting was called to order by President H. E. Bradford, of Marlboro, who spoke as follows: "This is the first meeting of the New England Street Railway Club, which was formed a short time ago at Young's Hotel, Boston. We met there in a social way, but the outcome of the meeting was the formation of the club. I was appointed president, and possibly a mistake was made by the club in choosing me as its first president.

"I think the necessity of such a club will be accepted by all street railway men, as it can do much for the operating man, especially to subordinates, by interchanging ideas. The officials in the transportation department of the Boston Elevated Railway Company, Boston, meet once a week and exchange ideas of operation, and it must be evident that this plan, if followed out, is beneficial. We are not very strong, but all associations in existence started in this feeble way; it is a case where we must put our shoulders to the wheel.

"We were in hopes to have E. C. Foster, vice-president and general manager of the Lynn & Boston Railroad Company, with us to-night, and regret his inability to attend, as he would be a very desirable speaker. However, as we are a little late in getting started it seems advisable that Mr. Stone, of the Electric Storage Battery Company, address the meeting first on 'The Demands for Chloride Accumulators by Street Railways.' There are some who would like to catch trains, and at the same time would be disappointed if they did not hear his remarks."

The Demand for "Chloride Accumulators" by Electric Railways

BY FRANK J. STONE

It is our pleasure this evening, in response to a request from the executive committee of this club, to present to you a few facts and figures relative to the demand for "chloride accumulators" by electric railways. Mr. Davis has prepared for us curves and data which we felt confident would be interesting and instructive, as they will not only explain why the demand for "chloride accumulators" has been so great, but will, I feel satisfied, enlighten you regarding problems which you may possibly have before you at this very time. The very best evidence to enable you to verify these figures and to confirm our statements is that to be secured directly from those who have the battery in operation on their systems, and it is with this end in view that I shall this evening call to your attention the results of our work in actual practice.

Looking back twelve years, when first entering the storage-battery field, and thinking of our early struggles, I cannot but compare our methods and results of that time with what we are achieving at the present day, and I feel deeply gratified with the reward of patient effort. We have all of us, without doubt, I believe, felt the full force and effect of that harsh, but thorough, teacher, experience, and as a result of her teaching we have learned what has hitherto been lacking to increase the efficiency and reliability of the trolley system, and I am proud to say that the Electric Storage Battery Company stands to-day in a position to supply the much-needed type of apparatus.

It would appear, then, that our interests are mutual, and I am glad of this opportunity to give expression to our views as to the value of the chloride accumulator in electric street railway practice, which views you will find are those freely expressed by our patrons. You have but to look upon the countenances of those among you who have become users of the storage battery, and consequently strong advocates of the system, to appreciate the good results that have been attained. For the battery serves well in more ways, perhaps, than in attaining those special ends for which it is designed. While its purchase may be made only with a view to saving fuel or to avoiding the purchase of other apparatus, which at times of light load would be operated under very uneconomical conditions, or to replace copper investment, in addition to these and its many other material advantages, the battery system offers something which cannot be shown in dollars and cents. What I refer to is the advantage of having on hand at all times a reserve supply, and while it would be, of course, impossible for any of us to say what is the value of this, it would be hard to find a user of the battery who has not something of a most favorable nature to say on this point based upon his own experience. We know that interruption to street railway service on Sundays and holidays especially means as a usual thing a heavy loss both in money and prestige. It may not, perhaps, pay to install a plant with this end alone in view, but it is a feature of the system that appeals strongly to all. There is in it a sense of security; you have something laid up for a rainy day; it is always there between your engines and your load, between you and the public; it is a guarantee of the efficiency and reliability of your road.

It is but natural for us to desire to profit by the experience of our neighbors, and to that end also I am bringing to your attention this evening some of the attractive features of such of our installations as I felt would be of interest to you, with some remarks on the experience of their owners. I might say in this connection that in addition to over fifty large Edison central lighting installations we have now in operation more than one hundred street railway plants, the greater number of which have been installed within the past few years. The total capacity of these batteries is approximately 160,000 kw-hours. The railway systems in connection with which they are installed operate over 3000 miles of road.

The Union Traction Company, of Philadelphia, has now in operation six chloride accumulator installations, the first of which is now in its fifth year of service. With this battery you are all no doubt somewhat familiar, from the description given by Charles Hewitt, electrical engineer of the Union Traction Company, in his paper read before the American Street Railway Association in 1897. In this he goes very fully into the subject of the value of the installation to his road. The five other batteries on the road have been installed within a year and remain a standing testimonial to the battery system. The case is simply one where, after having one battery in operation for several years, the traction company has called upon us to install five others, making the aggregate capacity about fifteen times that of the first. It may be interesting to mention that no renewals whatever have been made in any of these plants.

The Woonsocket Electric Machine & Power Company contracted in 1896 for a battery of 400 amps. capacity at the one-hour rate, designed for service on the trolley road, and also for carrying the load of the Edison three-wire system in case of emergency, in the latter case the battery being thrown into two sections in parallel, with the proper controlling devices. In the railway service the battery acts simply as a regulator, taking the place of all generating apparatus that would be required to furnish current above the average demand, and keeping a practically constant load upon the generators in operation by instantaneously responding to the sudden demands incident to the service. The voltage fluctuations at the power house rarely exceed 2 per cent. Although the battery is rated for a discharge of only 400 amps., it is frequently discharged at as high a rate as 600 amps., and at times at over 800 amps. As a reserve, the battery has frequently demonstrated its value. During a breakdown at the station, when it was found necessary to shut down the machinery, the battery carried the entire railway load for some three and one-half hours. No renewals whatever have been made, and the plates are to-day in apparently perfect condition. We have a written statement from L. C. Lincoln, manager of the company, to the effect that during the first year of operation the battery netted them a saving in coal of about 30 per cent, and in labor of $600.

A very novel installation is one that we have recently made for the Brooklyn Heights Railway Company, consisting of 248 cells of type 27-G, weighing approximately 300,000 lbs., and installed in two rows, with an aisle between, upon seven freight cars, six cars having thirty-six cells each, and one car has thirty-two cells and the switchboard. This is for operation at Sheepshead Bay, upon the Coney Island line, and in summer the battery is run out near the end of a long feeder line, and at this point connected up. As the heavy traffic, however, does not last more than three or four months of the year, the battery is hauled back at the season's end to the most advantageous point on the elevated system of the company. This is a case where the battery serves a remarkably good turn, in view of the extraordinarily heavy loads upon the line, with insufficient copper for the maximum during the summer season only. The movable battery solves this difficult problem and saves the interest upon the otherwise necessary investment and the maintenance of either additional feeder or stationary battery for eight or nine months of the year. In operation, it will be seen that the copper as at present installed is amply sufficient with the aid of the battery, this being due to the fact that the battery takes the fluctuations, so that the current upon the line is reduced to the average.

On the system of the Worcester & Suburban Street Railway Company we have installed two chloride accumulator batteries, one at the power house at Leicester, having a capacity of 400 amps. at the hour rate of discharge, with space in the tanks for increasing its capacity by the addition of plates to the extent of 50 per cent. This is a typical station battery, which serves to equalize the load, thus enabling them to shut down one large generating unit, which would otherwise be operating under uneconomical conditions. The other battery is located at Worcester, some 12

miles from the power station, and serves to keep up the potential on the line in that vicinity. The benefit of the battery system in all its force is felt and appreciated in this case, but I will at this time merely call your attention to the improvement in the service on the road which has been experienced since the installations were made. Owing to higher voltage, better speed, closer connections and greater comfort are obtained, and with the finer equipment which it has been found possible to operate, the riding has increased distinctly, and, consequently, the revenue.

On the Woronoco Street Railway system, at Westfield, Mass., we have a station battery in operation which is proving itself a fuel and labor saver. Its use renders possible the shutting down of one engine and the operation of the entire plant, comprising the engines, boilers and battery, by one man, excepting on Sundays and gala days.

The following is a list of the roads in New England using chloride accumulators:

Maine—Sanford & Cape Porpoise Railway Co.; Biddeford & Saco Railroad Co.; Waterville & Fairfield Street Railway Co.

New Hampshire—Union Electric Railway Co., Dover; Laconia Street Railway Co.; Boston & Maine Railroad Co., Portsmouth; Portsmouth, Kittery & York Street Railway Co.; Keene Electric Railway Co.

Vermont—Barre & Montpelier Traction & Power Co.; Bellows Falls & Saxton River Railway Co.; Springfield Street Railway Co.

Massachusetts—Worcester & Suburban Street Railway Co.; Norfolk Western Street Railway Co., Westwood; No. Abington Light & Power Co.; Framingham Electric Railway Co.; Woronoco Street Railway Co., Westfield; Newton & Boston Street Railway Co., Newtonville; Boston Elevated Railroad Co., Chestnut Hill Reservoir.

Rhode Island—Pawtucket Electric Co.; Union Railroad Co., Pawtucket; Pawtuxet Valley Street Railway Co., Riverpoint; Woonsocket Electric Machine & Power Co.; Rhode Island Suburban Railway Co., Riverview; Seaview Railroad Co., Wickford; N. Y., N. H. & H. R. R. Co., E. Providence and Brayton, Mass.

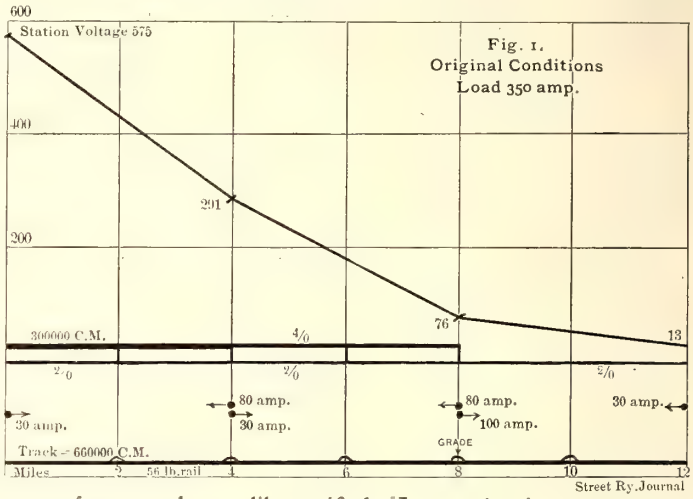
Connecticut—N. Y., N. H. & H. R. R. Co., Hartford and Forestville.

Besides these, many of the principal street railway companies in other parts of the country are using these batteries.

It is rather surprising to me sometimes to hear the company criticised for owning and controlling the exclusive right to manufacture storage batteries, after it has purchased the same (the purchases covering, I believe, over 425 patents). The criticism is a most unjust one, as the Electric Storage Battery Company, by the expenditure of large sums of money and the untiring efforts of its staff, has succeeded in giving to the electrical world a much-needed and very valuable type of apparatus in the form of a commercially successful storage battery, and that at a very remarkable reduction in price. In explanation, I would say that in the chloride accumulator we find a storage battery capable of enduring a discharge rate sufficiently high to totally discharge it in one hour. With the earlier forms, owing to the inability of the battery to discharge at high rates without injury, the purchaser, or rather the inquirer, discovered that he would be obliged to purchase a battery based upon the ten-hour rate, to meet his requirements. For example, if he wanted a battery capable of discharging at the rate of 400 amps., in taking care of the fluctuations on his railway circuit, he would be obliged to purchase one rated for a discharge of 400 amps. for a period of ten hours, or a 4000-amp.-hour battery, which would make the price five times what it need be now. In this regard alone it is plain to be seen what the Electric Storage Battery Company has accomplished in reducing the price to such a figure as to permit of commercial use, and this is one reason why so many chloride accumulator installations are being made at the present day. Aside from this, it must be very comforting when purchasing apparatus to know that you are buying not only the best thing that could be produced in your own country, but the best that the world can afford, for, owing to the existence of an alliance with the largest manufacturers of storage batteries in England, France and Germany, the Electric Storage Battery Company secures the benefit of all past and future improvements.

The plates of the chloride accumulator derive their great advantages over former types from certain remarkable details of form. The conducting grid is made up, not of lead, but of an alloy, which is not in any way acted upon by the acid solution. One result of this is at once apparent, and that is the doing away forever with the troublesome "buckling." The positive plates are so constructed that the effects of the expansion and contraction of the active material are reduced to a minimum, while at the same time this active material is very intimately connected with the conducting grid, and affords a large area to be acted upon without resistance between it and the support. The same structural strength is found in the negative, obtained practically in the same way, while the active material is so prepared as to possess the necessary porosity to a most remarkable degree.

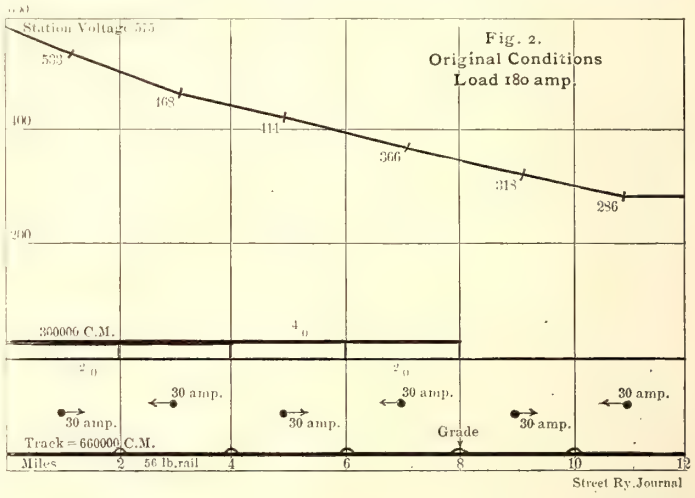
It is the policy of the company in its negotiations with a prospective customer to have the engineer assigned to the case make his report purely from the standpoint of a consulting engineer, and for that purpose I do not hesitate to say that I believe they have selected as able and conscientious a staff as can be found among the fraternity. The report is based upon actual facts as they are found to exist in the situation under investigation, and these facts



can, of course, be readily verified. It contains in most cases a very conservative estimate of the saving to be created and through what sources, with reference also to the other advantages which may be obtained by the application of the battery. There are very few cases where a battery cannot show a saving, especially in street railway work. Regardless of this, however, we are always pleased to be called upon to make an investigation and report, and further, you will please remember that you have all of you a standing invitation to accompany us on a tour of inspection of any or all of our installations, severally or collectively, as may suit your convenience.

Paper by Philip W. Davis, Engineer

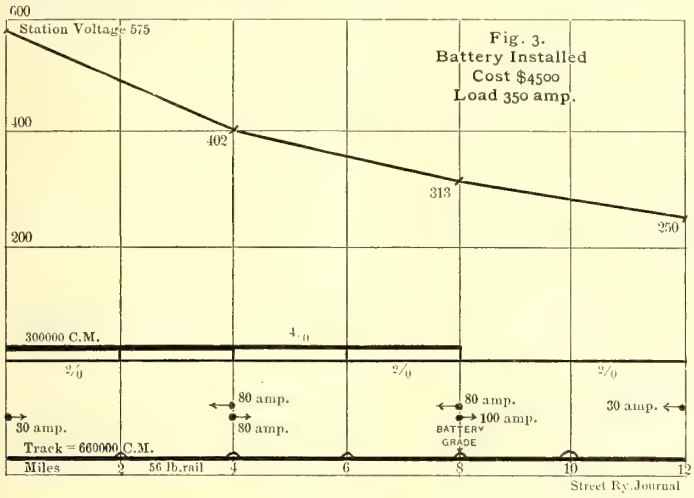
I have always found the street railway man of an inquiring turn of mind. Necessity has made him careful, and he does not always



confine himself to the question, "does it pay?" he is interested in knowing "why." It is this side of the question that Mr. Stone has bidden me pursue, and I will try to do it without being unpleasantly technical, but I trust you will excuse me if I introduce a few figures.

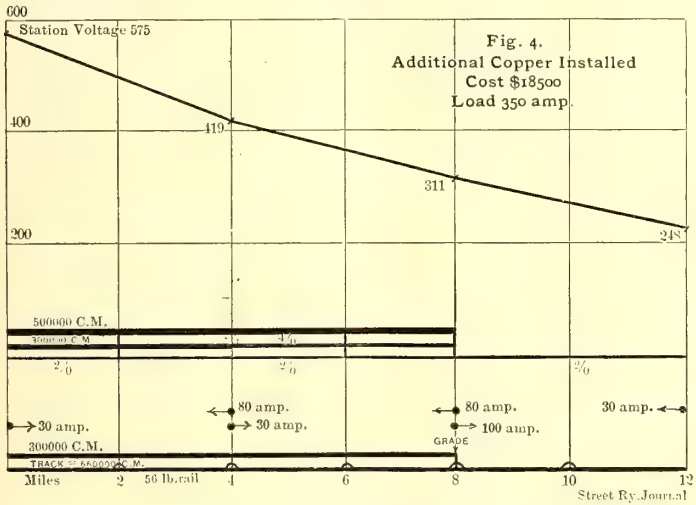
With a view of avoiding the want of exactness which usually accompanies a general statement, I have figured out the solution of a railway transmission problem by three different methods and have presented it in a graphical form so that the results may be easily compared. While this problem is a special case of a line battery, still I think it illustrates fairly well the value of a storage battery in all its phases. The diagrams represent at the bottom a single track with turnouts, marked by loops, 2 miles apart. It is supposed that 8 miles from the power station is a rather long and steep grade, reaching perhaps as high as 8 per cent. The track is 56-lb. rail, and is equivalent to about 660,000 circ. mils of copper. The line consists of a 00 trolley throughout, a 300,000 feeder running out from the station for 4 miles, and a 0000 continuing to the grade,

4 miles more. The cars are shown as dots, with arrows indicating their direction. The line voltage for the instant under consideration is indicated above the copper. The load with six cars operating is found to average about 180 amps., and to have fluctuations reaching to 350 amps., occasionally a little higher. The line voltage has been calculated for two instants, the instant of average load, as shown in Figs. 2, 5 and 7, and the instant of maximum load, shown in Figs. 1, 3, 4 and 6. The road originally was 10 miles long and operated five cars, and there were, of course, four turnouts, not counting those at the ends. The lowest voltage encountered on the line at the time of heavy pulls was 220 at the grade. It was just possible to operate. But when it becomes desirable to add the extra 2 miles shown in the diagrams to the road



and operate six cars, the lowest voltage on the line at the moment of maximum pull will become, as you see on Fig. 1, 13 volts at the end of the line and 76 volts at the grade. Evidently this situation needs help.

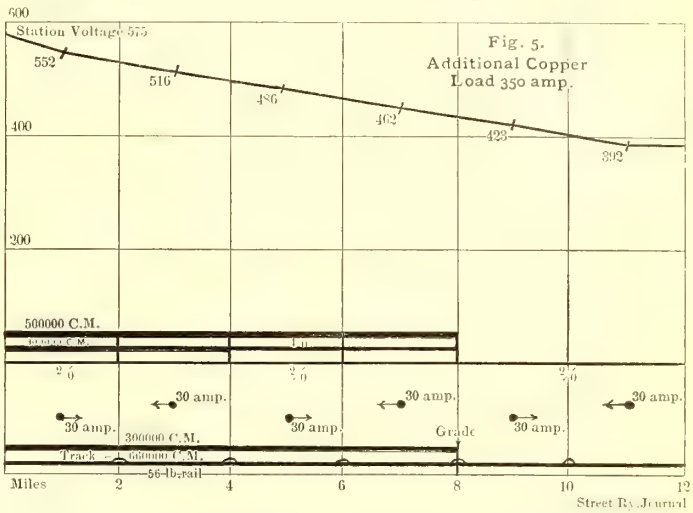
Now let us apply a battery to this road without in any way altering the copper. In the first place, where shall it be put? The heavy grade is a source of much of the trouble, it is there that the heaviest pulls come. In addition, at the foot of the grade is a car house. If the battery is put there it will be an easy matter to give it what little attendance it needs. The next step is to determine what voltage the battery must be capable of. The battery is to be operated as a regulator, alternately charging and discharging; its voltage then must be the same as the average voltage maintained at the battery location by the copper. If the volt-



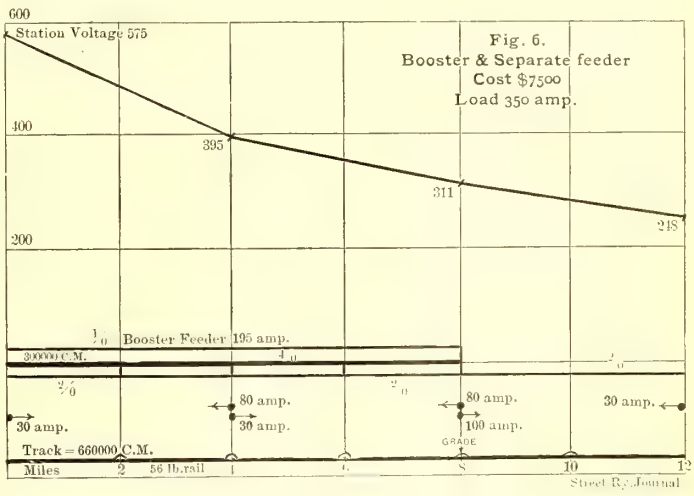
age of the battery were any higher it would discharge more than it charged, while if it were lower it would become overcharged. This voltage is about 340 volts, as shown by Fig. 2, and will require 163 cells. The next thing to be decided is the capacity of the battery. Evidently it must be large enough to take everything which the station cannot take. When discharging at its maximum rate the pressure at its terminals will fall about 27 volts, bringing the line voltage at the grade to 313 volts (see Fig. 2). This limits the drop between the station and the grade to 262 volts. With this drop the station can only supply 195 amps., and the battery then will be called upon for 125 amps. The nearest thing to this capacity is an E-13, rated at 120 amps., at the hour rate, and 163 cells of E-13 installed, with a switchboard mounting a circuit-breaker, an ammeter, a voltmeter and a switch, and making an allowance for the construction of a room or battery house, would cost about $4,500. In return for the investment the line voltage at the grade has been raised 237 volts, and is now sufficiently high to permit of very satisfactory operation of the road. In addition, the station has been relieved of 125 amps., or nearly 36 per cent of the load at the time of maximum pull.

Had copper been installed, as shown in diagrams Nos. 5 and 6, to give the same line voltage at the grade it would have required 8 miles of 500,000 feeder in the overhead line and 8 miles of 300,000 circ. mil feeder in the track, or over 102,000 lbs. of copper, which, at 17½ cents per pound, and allowing something for erection, would cost about $18,500, or about four times the cost of the battery.

We might, perhaps, use a booster and separate feeder to the



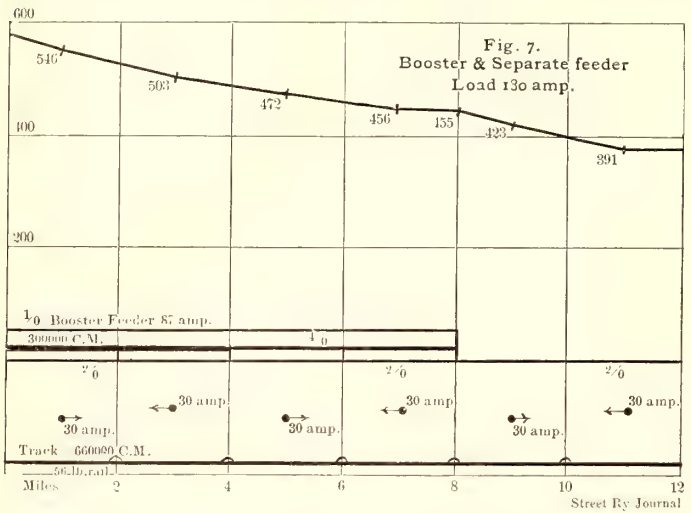
grade, as shown in diagrams Nos. 6 and 7. The less the investment in copper for this feeder the higher will be its resistance and the greater the voltage necessary to force current over it; therefore, the greater the cost of the booster. For the sake of avoiding the construction of special machinery it is also desirable to keep the voltage of the booster down to the limits of standard apparatus. A 0 wire and a 125-kw, 750-volt, motor-driven machine, series wound for 3.67 volts per ampere of load, is a combination that will give about the lowest first cost. The machine will cost about $5,000, and the copper, erected, about $2,500, making an investment of $7,500. Nor is this the end of the story: the ground drop is greater without the battery than it is with the battery, because, without the battery all the current to supply the demand must go out from the station and return to it at all times,



while with the battery, during the heavy pull, part of the current returns to the battery instead of to the station. As a result, the booster is called on to feed 195 amps. through the special feeder, while the existing copper only carries 125 amps. To force this load through 8 miles of 0 feeder requires 793 volts, of which 716 volts will be furnished by the booster, the remaining 77 volts being found as drop in the existing copper. This means an increase in the demand for power of 140 kw, being an increase of 70 per cent. If the booster has an efficiency of 65 per cent the demand on the generator will be increased from 70 per cent to over 100 per cent owing to the losses in the booster itself. It is evident then that the installation of a booster will more than double the maximum fluctuations and will add to the size of the machinery which must be in operation in the station, and also the coal bills. The extra power required does not maintain the same proportion at all loads,

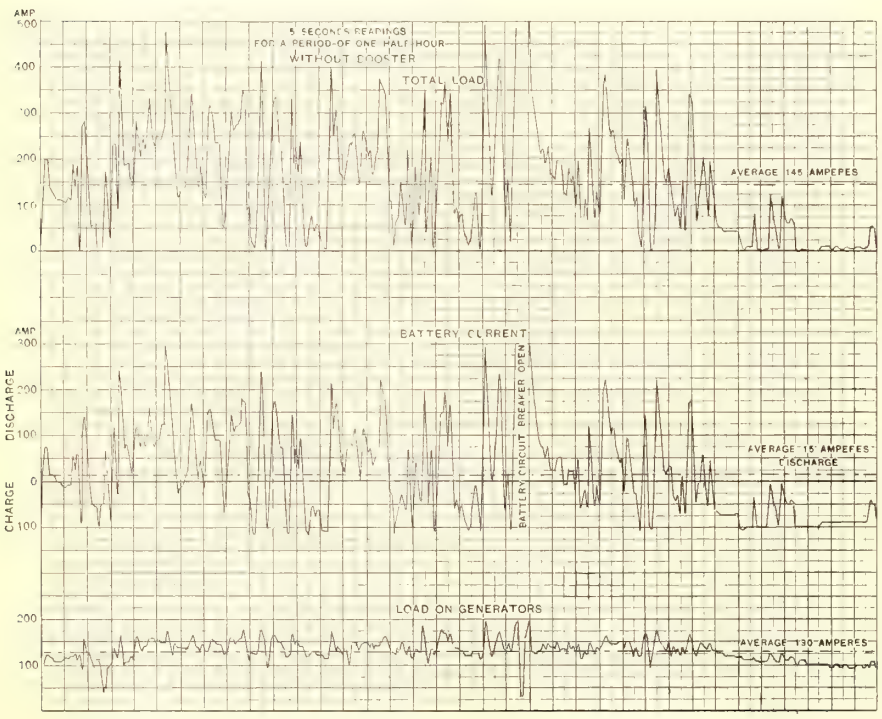
thus at average load 87 amps. at 319 volts, or allowing for the booster losses, 42 kw is the extra power demanded, and is an increase of 42 per cent.

In view of the losses back of the generator, and the decreased load factor for machinery operated, it is probably a conservative estimate to say that if this booster was installed the coal bill for the year would be increased between 50 per cent and 60 per cent. A station of this size would burn perhaps 2000 tons of coal per year, which, at $3.50 per ton, would be $7,000 per year, so that an increase in the coal of 55 per cent would mean an increased yearly



expenditure of $3,500. It is interesting to compare the operation of the station machinery under the two systems. The original station load averaging 103 kw, with fluctuations reaching 200 kw, could be operated with machinery of 150-kw capacity at a load factor of 69 per cent. With the battery the fluctuations come down to 130 kw, and the station could be operated with machinery of 100-kw capacity at a load factor of 100 per cent. The booster, on the other hand, brings the fluctuations up to 400 kw and requires the station machinery to be of at least 250-kw capacity, operating at an average load of about 140 kw, or 56 per cent load factor. The

Fig. 8



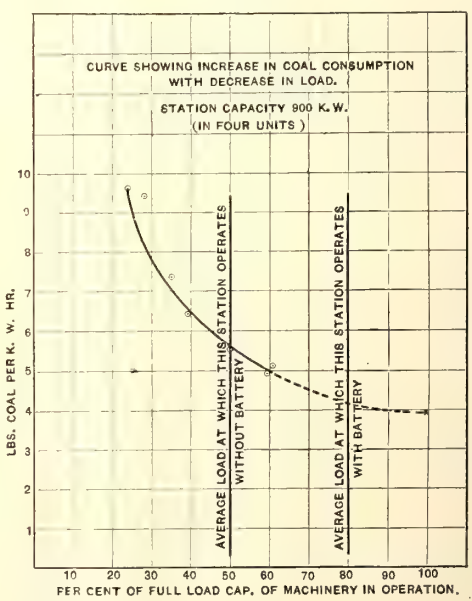
battery adds one other advantage not possessed by machinery, that of twenty-four-hour power on the line, for emergency work, lights for repairs, night operation, etc., and this without the operation of any machinery in the station.

When placed in the power station a battery cannot, of course, have any influence on the copper question, but it is then in the most favorable position to act as a regulator and maintain a steady load on the machinery which operates, thereby preventing the necessity of operating any more units than are just enough to take care of the average load. The electrical transportation of passengers by direct-current apparatus has long ago demonstrated its right to exist as an industry. It has passed the stage of a new enterprise and it has reached the point where future improvement will take the form of refinements in methods of operation. The storage battery offers the most inviting improvement in station operation that has come up since the beginning of the industry.

A glance at any diagram of a railway load is all that is needed to show the value of storage of power in a railway generating station. I have here a load curve (see Fig. 8) taken from a small railway where, as you see, without a battery it would be necessary to have in operation machinery capable of developing 290 kw or 500 amps. at 575 volts, which would be carrying an average load equivalent to only 75 kw, or 130 amps. A battery was installed in this station and the result is shown very clearly by the three curves indicating respectively line load, battery load and generator load. It will be interesting, I think, to lay before you in this connection the reasons that underlie the want of economy in an engine operated under light load. It proceeds from two causes—engine friction and cylinder condensation.

In the absence of exact data concerning the power required to overcome friction in an engine, 10 per cent of the rated capacity is a safe figure to assume. Thus, take the case of a 200-hp engine, it requires 20 hp to keep it moving; if it is running light or without load all the coal burned to produce the necessary 20 hp is wasted. If the load averages 20 hp half of the coal burned is wasted. If it be necessary to operate a 200-hp engine in order to care for a load averaging 60 hp on account of the fluctuations of the load it is necessary to burn sufficient coal to produce 80 hp; whereas, if it be possible to take care of this load with an engine whose full load is 60 hp the friction loss is only 6 hp, and it is only necessary to burn coal to produce 66 hp, a clear gain of 14 hp, or 17 per cent on friction reduction alone. The second factor, or cylinder condensation, proceeds from the property which steam has in common with all gases of cooling as it expands. As you all know, steam is admitted to the cylinder at boiler pressure for a portion of the stroke only. After that it is allowed to expand. If the engine were a simple, non-condensing engine the steam would enter the cylinder at perhaps 100 lbs. pressure, and expand down to 20 lbs. Steam at 100 lbs. pressure has a temperature of 328 degs., while steam at 20 lbs. has a temperature of 228 degs. It follows then that when steam at boiler pressure is admitted to a cylinder which has just exhausted steam at 20 lbs. pressure it finds the cylinder walls 100 degs. lower in temperature than itself. To the steam this is a good deal like going into an ice box, and so enough steam will instantly condense on the walls of the cylinder to bring their temperature up to that of boiler steam. On this account considerably more steam has to be supplied to the cylinder than that required simply

Fig. 9



CURVE SHOWING INCREASE IN COAL CONSUMPTION

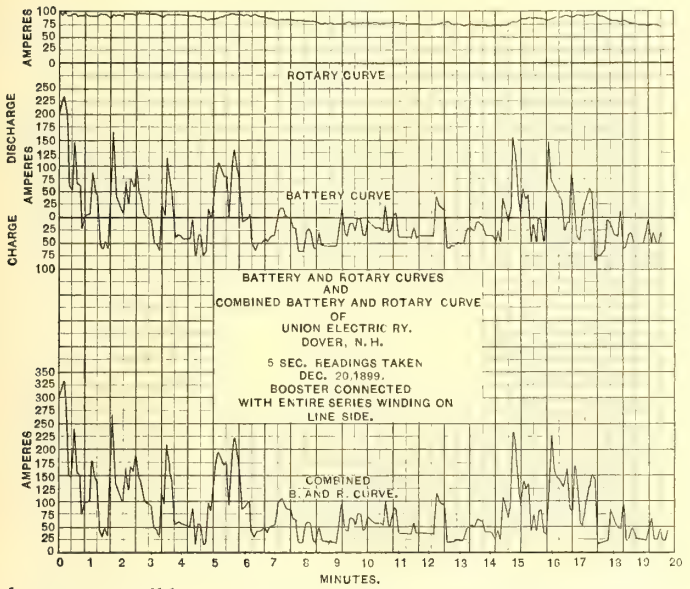
to fill the space behind the piston. This condensed steam, of course, does no work, but requires just as much coal to produce it as if it did. Now, an engine working under light load cuts off earlier than under heavy load, and therefore its steam expands more, with the result that the cooling of the cylinder walls is carried further and more steam is condensed to warm them up. This action may be noted and measured by weighing the exhaust steam which comes from an engine, and comparing it with the quantity of steam called for from the indictor cards. The discrepancy is sometimes startling.

However, what interests you is how much these combined

effects enter into the cost of production of power in such plants as the average railway operates. Here is a curve (see Fig. 9) taken from the records of a power station containing four high-speed compound engines belted to four 225-kw generators. The loads on this station vary very widely on different days, and the curve represents the pounds of coal burned to produce a kw-hour of energy under conditions averaging from heavy load to light load on the machines that were operated. The curve shows that on certain days the machinery that operated did not average a load of more than 25 per cent, and that under such circumstances it took 9½ lbs. of coal to produce every kw-hour of energy. Of course these days were very infrequent. This station averages a load equal to about one-half the capacity of the machinery which is in operation, and its coal economy is 5½ lbs. per kw-hour. The type of machinery operated here is capable of doing 4 lbs. when operated steadily at full load. By the installation of a battery it

Fig. 10



becomes possible to average at least 80 per cent load factor and 4½ lbs. of coal per kw-hour, a clear saving of 1¼ lbs. of coal on 5½ lbs. for every kilowatt produced, or a reduction of 22¾ per cent in the coal bill.

A very interesting application of the storage battery is found in connection with the rotary converter and polyphase transmission for long-distance work. A road operating rotary sub-stations with batteries is in a position to obtain as much benefit from the batteries as if they were located in the station. The machinery, including the alternating-current line and the rotary converter, need only be designed for the average load, and can be operated at an approximately steady load. It is also a marked advantage to be able to start the rotary from the direct-current end with the aid of the battery. When a rotary is started from the alternating-current end it demands a very heavy current; this current is out of phase with the e. m. f., and does not represent as much energy as it would in direct-current work, but its heating capabilities are just as great, and there is not a little danger of burning out some of the apparatus. Sometimes in rotary plants, where the starting is to be done from the alternating-current end, a small induction motor is added to the rotary to be used in starting. This means an extra piece of apparatus and an increase in the investment which lies idle. The presence of a battery is also of value in preventing pumping between rotaries and their generators by preventing the fluctuations of load, which tend to start the action. Where other apparatus is operated from the line which feeds the rotary the battery has a value as a regulator, as it prevents the continual change of phase relations between current and e. m. f., accompanied by the production of wattless currents and the consequent useless heating and surging of the effective voltage, which would ensue if the fluctuations of the railway load were allowed to fall on the alternating-current line.

I do not wish to leave this subject without touching on the question of the booster for use with batteries as a voltage compensator. The operation of a storage battery, that is, its charge and discharge, cannot take place without a change of voltage at the terminals of the battery. When a battery is placed on the line there is always sufficient change in voltage to permit it to operate. In the station, however, this is not always the case. Sometimes it is desirable to have the bus-bar voltage maintained very steady, in which case a booster becomes a necessity. It is at all times a useful piece of apparatus, as it adds flexibility to the system by bringing the battery absolutely under control, so that a turn of the wrist enables the station attendant to force either charge or discharge independently of the conditions of voltage and load that may be present in the station at the time. While the booster is an expensive machine per kilowatt, its energy capacity is small. It may be capable of carrying 400 amps., and yet its capacity would not exceed 16 kw.

Owing to the change of voltage at the terminals of the battery, a small portion of the fluctuations will fall on the generators unless a booster is used. If it is really desirable to eliminate the entire fluctuation, a booster must be used. The first curve that I brought to your attention is an example of battery regulation without a booster.

Fig. 10 is an example of a rotary station with battery and booster where the load fluctuations are practically eliminated from the load of the rotary. Three curves taken from the plant of the Woonsocket Electric Machine & Power Company show what may be accomplished with a booster in the way of voltage regulation, the maximum variation being within 2 per cent, or 10 volts. On small roads, however, the booster is usually a needless refinement. There is no need of keeping the voltage at the bus-bars down to a variation of ten volts, a variation of 50 volts is often not too great to be tolerated. Moreover, it should be borne in mind that a small fluctuation in the generator load does not mean much change in the steam distribution in the engine, owing to the effect of the fly-wheel, and again, the fluctuation in watts or energy demand on the dynamo does not increase in proportion to the drops. Perhaps the strongest point in favor of a booster in a railway plant is the desire of the railway manager who decides to purchase a battery to see among other improvements a higher average voltage at his station bus-bars; accordingly he calls for a sufficient number of cells to equal the desired voltage. It happens sometimes that after the installation of the battery it is discovered that the generators are not able to maintain an average voltage equal to that of the battery, and the result is that it is impossible to keep the battery properly charged. If the voltage of the generators cannot be raised, the remedy is to cut out of circuit enough cells to bring the battery voltage down to a level with the generators. If the extra voltage is really desirable it can only be obtained by the addition of a booster to the plant.

DISCUSSION

A short discussion followed the reading of the papers. Mr. Davis was asked if the proportion of load due to friction was usually greater or less than 10 per cent. He replied that this varied from 6 per cent to 12 per cent, and was undoubtedly very much less in large machines than in small ones. Mr. Davis also stated, in answer to inquiry, that in the first case described in his paper no copper whatever had been added. He also explained that the battery was figured for the average potential at the point of installation, and to take care of the demand above the average.

Mr. Stone was asked to make a few remarks concerning the durability of the storage battery. He replied that the best evidence as to the durability of the battery was to be derived from the experience of the users of the same. In the case of the Woonsocket plant and in many others, among which might be mentioned the Union Traction Company, of Philadelphia, the wear and tear after a period of several years' service had been found to be practically nothing. In street railway regulating batteries especially, the wear and tear is found to be very slight indeed. This is due to the fact that the battery is rarely, if ever, totally discharged, and therefore the chemical action under the usual conditions of momentary charge and discharge is but very slight. On a visit of a prospective purchaser to the Woonsocket plant, Mr. Lincoln, the manager of the company, was asked, in Mr. Stone's presence, whether he would repeat the installation of the battery under the same circumstances as those under which their battery was first installed, and Mr. Lincoln replied that he certainly would.

E. C. Spring, of the Norfolk Western Street Railway, was asked by Mr. Bradford, the president, what he had to say in regard to the storage batteries in operation on his road. He then spoke as follows:

"While I did not come here to advertise the Electric Storage Battery Company, a little incident happened about a month ago, which will illustrate what the battery system does in our case. About one-half of our road is operated from a direct-current machine at the power station, and the other half from rotary converters at Westwood, on the triphase system. The engine that was running the direct-current machine at Medfield went to pieces, thus shutting down the direct-current end of the line. All that was operating then was the three-phase system from Medfield to Dedham. The belt in the power station gave way and the road was then shut down on either end. I called up the car house by

telephone, and told the foreman that both ends of the line were shut down, when, to my surprise, he replied that everything was all right there, and there must be some mistake, as the cars were running on regular schedule time. 'Go in and see if the rotaries are not shut down,' I answered. He did so, and found the rotaries running as usual. This simply shows that the battery was backing up on the rotaries, and running the road at the same time. We think a great deal of the battery. Its operation is perfect. It enables us to start the rotaries from the alternating current end, and is especially useful in night work."

President.—I think it advisable to take up the business of the evening. I understand that some members of the Massachusetts Street Railway Association favor us uniting with them. In the first place the ordinary street railway man is not eligible to membership in that association. The street railway companies are members of the association, and each company is entitled to appoint a representative in the following manner, which I think is correct. A company with a capital stock of $100,000 is entitled to one representative, $100,000 to $200,000 two representatives, and all over $200,000 three representatives. This association is composed of the higher officers of the different companies, and the ordinary superintendent as well as other practical street railway men would not feel at home at these meetings. Although we are at all times willing to carry out any suggestions which the street railway associations of New England may offer, we do feel that this club of ours will enable us all to meet and discuss the practical operations of the different roads.

The minutes of the formation of the club were read, as were also the by-laws and constitution of the club, and were referred to the next meeting of the club.

Mr. Whitaker, general manager of the Portland & Yarmouth Street Railway Company, Portland, Me.—I did not come here with the intention of speaking, but simply came to listen and get all the information I could. I think the idea of a club of this kind is desirable, and it is certainly a necessity for the benefit of all who have anything to do with the practical operation of a road. The variety of subjects that can come up for economical management is a fruitful source of interest to all superintendents and railways. I am an outsider practically, although it is my intention to join the club.

Mr. Pastell, electrical engineer of the Lynn & Boston Railroad Company.—I have been a member of the New England Railroad Club for some three years, and attended most of its meetings, and I think there were only two meetings that were of interest to a street railway man. I think this is an excellent scheme, and I would suggest that a special meeting be called for two weeks from to-night, Sept. 19, in order that the constitution and by-laws be accepted and sub-committees appointed, especially a committee on publication. Every street railway man will be interested in the papers read before this club, and there ought to be some means devised whereby those who are unable to attend may have an opportunity to read them.

Mr. Henderson, of the Newton Street Railway Company.—I think the papers read to-night should be published in some magazine, and I, for one, will certainly favor that something be done in that direction.

Secretary.—I think I am safe in saying that the Street Railway Journal would be very glad to publish in its weekly editions the proceedings and papers read before the club, but I have no assurance of it. I will write the publishers and see what they say. If they do not feel disposed to publish these papers I think the club ought to do it. The New England Railroad publishes a magazine every month containing the minutes of each meeting and the papers read, together with illustrations, and it has proved a success.

Mr. Granger, of the Boston Car Wheel Company, Boston.—I have been very much interested in the progress of the New England Street Railway Club, and have made it my business to talk to all my friends, not only those interested in the operation of street railways, but also in the supply business, and every time I have made mention of it the parties I have spoken to have been anxious to join. I have a list of friends who are, by the way, street railway men, who would like to become members, and have asked me to submit their names, and if the committee will accept them for membership, and send them their notice of being elected to membership they would be very glad to attend the meetings. Parties in New York and Boston would be glad to become members.

President.—I would suggest that Mr. Granger leave his list with the secretary, and the same will be taken up at the next meeting of the executive committee.

President.—I have been on a small road for some years, and it has been impossible for me to keep up with the larger roads, regarding new devices, etc., and I would like to know something about the rotary snow plow.

Mr. Spring, of the Norfolk, Western Street Railway Company.—I would suggest that the executive committee get someone to speak on the snow plow question at the next meeting, for the subject will be very interesting, especially to suburban lines, where they encounter considerable difficulty during the winter months in keeping the snow clear from the tracks.

(It was voted that the committee act on these suggestions.)

Voted: That a vote of thanks be tendered Messrs. Stone and Davis for their interesting papers.

Voted: That a vote of thanks be tendered to the Rand Avery Supply Company for the free use of its rooms for this meeting, and for the cigars which the members seemed to enjoy.

Mr. Henderson.—I think we ought to combine all our efforts to get a large number present at the next meeting of the club, which will be two weeks from to-night. I think if we make a strong effort we can get a very large crowd.

At this point the meeting adjourned.

Retirement of C. K. Durbin

After a long and successful term of service as superintendent of the Denver City Tramway Company, Denver, Col., Charles K. Durbin has resigned his position, and will engage in a private business enterprise. Mr. Durbin was held in the highest esteem by the company, and the directors with regret lose his services. His successor has not yet been appointed, and probably will not be named for several weeks. As a mark of regard, the company presented Mr. Durbin with a gold watch, suitably engraved, and adopted resolutions, given below, testifying to its appreciation of his work. The employees also presented Mr. Durbin with a handsome diamond ring and a set of link cuff buttons with diamond settings.

C. K. DURBIN

Mr. Durbin's connection with the company that has developed into the present Denver City Tramway Company commenced in June, 1888, when he was appointed auditor. In November of the following year he became superintendent. His term of service began when the development in street railway work had just started. The company was experimenting with the underground electric system on Fifteenth Street, and expended considerable money in endeavoring to make the system practicable. At the present time the system of the company covering the city of Denver is operated by the trolley. During the years of his superintendency Mr. Durbin has had experience with horses, steam dummies, the cable and electricity. During this same period the two most marked features of the company's system were introduced. First was the method of dispatching cars following the practice on steam railroads. This innovation has been adopted in Portland and Los Angeles, and has been found extremely serviceable in the operation of cars. The second feature was the method of paying the men. Each night the conductor pays the day's wages to the motorman and himself. This plan works admirably in practice. The office is required to handle a quarter less money; less work is required in the bookkeeping department, and the men like the arrangement far better.

Mr. Durbin has been successful in dealing with the employees in a marked degree. He has followed the policy of making the service lucrative and attractive to the men, so that they have been glad to hold their places. The schedule of wages was arranged with this idea in view. The first year the car men are paid 17½ cents per hour; the next two years, 20 cents; 21 cents the fourth and fifth years, and 22 cents after that. After five years' service the men have the right to wear one star on their coats, and after ten years they wear two stars. After ten years' service the employees are given uniforms by the company as presents. Last year ninety men received donations of this kind and 60 per cent of the present force have been in the company's employ more than five years. Mr. Durbin has had no trouble with the men, though he is a thorough believer in good discipline.

The resolutions which the board of directors adopted are as follows:

"Whereas, For upwards of fifteen years last past, Mr. Charles K. Durbin has been closely and prominently identified with the street railway enterprises in Denver, having served the Denver City Tramway Company and its predecessor companies during that period of time as superintendent, and

"Whereas, The untiring service rendered by Mr. Durbin has contributed materially to the upbuilding of the system of street railways in Denver in which we all justly take so much pride, and

"Whereas, Mr. Durbin is about to sever his official relationship with our company, for the purpose of entering upon private business; now, therefore, be it

"Resolved, That we, the board of directors of the Denver City Tramway Company, hereby express our deep appreciation of the earnest effort, absorbing interest and rare intelligence which have always characterized the official connection of Mr. Charles K. Durbin with our company, and

"Resolved, That his determination to withdraw from the position which he has so long and so capably occupied is a source of regret to each of us personally and as officers of the Denver City Tramway Company, and

"Resolved, That we hereby tender to Mr. Durbin our sincere thanks for the uniform courtesy, zeal and faithfulness displayed by him, in winter and summer, in storm and sunshine, during the hours of vicissitude as well as in prosperity, while acting as the superintendent of the Denver City Tramway Company and the companies which preceded it, and that we hereby extend to him the assurance of our best wishes for his future prosperity and happiness in whatever walk of life he may select, and

"Resolved, That a copy of these resolutions be presented to Mr. Durbin."

Annual and Quarterly Metropolitan Reports

The Metropolitan Street Railway Company, of New York, reports earnings as follows for quarter and the fiscal year ending June 30, 1900:

Quarter ending June 30	1899	1900
Gross receipts	$3,665,946	$3,849,354
Operating expenses	1,765,671	1,825,690
Earnings from operation	$1,900,275	$2,023,664
Receipts from other sources	77,768	79,245
Net income	$1,978,043	$2,102,909
Fixed charges	1,125,657	1,175,400
Net earnings	$852,386	$927,509

Year ending June 30	1899	1900
Gross receipts	$13,158,630	$14,721,550
Operating expenses	6,408,711	7,104,607
Earnings from operation	$6,749,919	$7,616,943
Receipts from other sources	366,893	351,985
Net income	$7,116,812	$7,968,928
Fixed charges	4,477,757	4,608,768
Net earnings	$2,639,055	$3,360,160
Dividends paid	2,471,675	3,145,891
Surplus	$167,380	$214,269

The balance sheet of June 30 shows:

ASSETS

Cost of road and equipment	$35,682,169
Stocks and bonds	21,644,457
Supplies on hand	103,778
New cons. on lines owned and leased to be distributed	18,068,359
Office furniture	18,304
Improvements, additions and betterments charged to leased lines	2,776,065
Bills receivable	271,886
Cash on hand	12,489,276
Open accounts	37,291
Total	$91,091,587

LIABILITIES

Capital stock, common	$44,960,900
Funded debt	21,750,000
Bills payable	8,756,736
Interest accrued	401,275
Dividends unpaid	786,815
Open accounts	374,280
Third Avenue R. R. Co. lessor construction account	11,419,834
Rentals and taxes accrued	621,830
Profit and loss surplus	2,019,915
Total	$91,091,587

PERSONAL MENTION

MR. BENJAMIN W. PORTER, formerly general manager of the Derby Street Railway Company, of Derby, Conn., was recently presented with a handsome set of Johnson's Encyclopedia in token of the esteem in which he is held by his former employees. There are eight volumes in the set, and they are bound in morocco.

MR. H. S. COOPER, whose resignation as general manager of the Ithaca Street Railway Company, of Ithaca, N. Y., was announced last month, has been engaged by a syndicate of capitalists as a street railway and operating expert. The plan is to undertake the reorganization or revamping of poorly paying roads, where there is a chance of improving their condition and placing them on a paying basis. The work will be carried on largely in the West and Middle West.

MR. L. B. STILLWELL has resigned as electrical director of the Niagara Falls Power Company, and will remove to New York City, where he will open an office as consulting electrical engineer. Mr. Stillwell has been connected with the Niagara Falls Power Company's electrical interests practically since their inception, the electrical machinery now in operation in the great 50,000-hp plant having been designed and constructed by the Westinghouse Electric & Manufacturing Company under his supervision while electrical engineer and assistant manager of that company, while as electrical director of the Niagara Falls Power Company he has directed the installation and operation of the plant since March, 1897. For the past two years Mr. Stillwell has given a large part of his attention to consulting work for other electrical enterprises, notably the equipment of the elevated railways of the Manhattan Railway Company in New York City, which is proceeding under his direction. Harold Winthrop Buck has been appointed electrical engineer for the Niagara Falls Power Company and its allied interests, including the Buffalo and Tonawanda companies, as successor to Mr. Stillwell. Mr. Buck is a graduate of the Sheffield Scientific School, and received his degree of electrical engineer from Columbia University. For the past five years he has held an important position on the engineering staff of the General Electric Company at Schenectady, N. Y. Philip P. Barton and Paul M. Lincoln, assistant superintendents, have been promoted, Mr. Barton having been appointed superintendent of the operating department of the Power Company, and Mr. Lincoln resident electrician.

L. B. STILLWELL

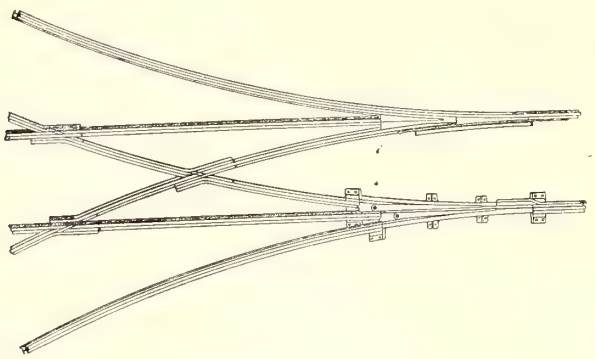
Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

ELECTRIC RAILWAY PATENTS ISSUED SEPT. 4, 1900

657,099. Railway Switch; G. H. Fairchild, San Francisco, Cal. App. filed June 22, 1900. A double switch for three way tracks consisting of a main or straight track and right and left branch tracks leading therefrom at about the same point, with two inde-

pendent switch tongues, one in the outside rail of one branch, and the other in the inside rail of the other branch, each tongue having



PATENT NO. 657,099

a suitable and correspondingly located mate in the opposite sides of said branches.

657,123. Car Wheels; H. W. Libbey, Boston, Mass. App. filed July 27, 1899. The invention consists in forming the car wheel in two parts, the rear portion being formed with a number of recesses and having an elastic tread around its periphery. The elastic tread is formed with ears of projections that fit into the recesses in the rear portion of the wheel.

657,154. Sill for Underframe of Cars; W. P. Bettendorf, Davenport, Ia. App. filed March 15, 1899. The sill consits of two continuous beams (or equivalents) arranged one above the other and extending from end to end of the car, and above the car bolsters, the beams being separated between the bolsters to form a truss, then brought into direct contact and union at points above the bolsters and again separated beyond such bolsters.

657,180. Car Fender; R. F. Preusser, Washington, D. C. App. filed Nov. 20, 1899. Structural details on a combined fender and wheel guard, the fender being adapted to be folded back against the dashboard out of way of coupler when not in use.

657,198. Striker Arm for Car Seats; J. S. Johnston, Newport, N. Y. App. filed Jan. 20, 1900. Structural details which allow the back to be reversed in position and at the same time furnish stops which limit movement of the parts.

657,445. Anti-Friction Bearing for Car Trucks; J. A. Patten, Baltimore, Md. App. filed Jan. 19, 1900. Each ball lies in a separate socket so that they are maintained in proper working position. Portions of casing are made so as to readily wear away as balls and other parts wear, so that weight will always be on the balls.

657,480. Car Seat; T. B. Cann, Wakefield, Mass. App. filed April 25, 1900. Details which provide means whereby the reversal of the back causes also a reversal of the position of the foot-rest frame and seat.

657,481. Car Seat; T. B. Cann. Wakefield, Mass. App. filed April 15, 1900. Modification of preceding patent.

657,490. Car Seat; D. M. Houston, Wakefield, Mass. App. filed April 15, 1900. Modification of preceding patent.

657,492. Railroad Tie; E. A. W. Jeffries, Detroit, Mich. App. filed May 24, 1900. An elastic railroad tie. The body or main portion of the tie is formed of concrete or artificial stone.

NEWS NOTES

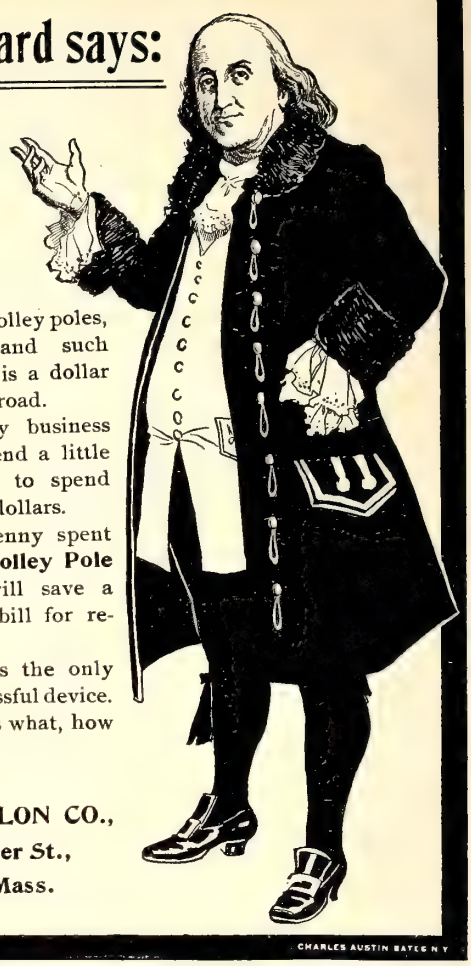
[*News notes for this department are solicited.*]

ATLANTA, GA.—Transfers are now granted from the lines of the Atlanta Railway Company, which run out McDaniel Street to McPherson Barracks and also out Cooper Street to Grant Park, to those of the Atlanta Railway & Power Company, of which the former company is a part. Transfers are given to all lines at the point of contact with the tracks of the Atlanta Railway Company.

JACKSON, GA.—A stock company headed by Capt. W. F. Smith, of Flovilla, has just purchased the Thomas shoals, on the Ocmulgee River. It is said that the deal is of considerable importance, and that the company intends utilizing all the power of these shoals and furnishing electricity in Jackson, Flovilla and Indian Springs. It is said that the company also contemplates changing the Flovilla & Indian Spring Railroad into an electric line and extending it to Jackson.

EAST ST. LOUIS, ILL.—The employees on the Day line and the Suburban line running between East St. Louis and Belleville and the local street railway lines in Belleville went on strike Sept, 5. No cars are running.

Poor Richard says:



"A Dollar Saved is a Dollar Earned."

A dollar saved from repairs to overhead construction, bent trolley poles, broken harps and such needless repairs is a dollar earned by your road.

It is ordinary business judgment to spend a little to save much, to spend pennies to save dollars.

For every penny spent on a **Wilson Trolley Pole Catcher** you will save a dollar in your bill for repairs.

The Wilson is the only absolutely successful device.

Our book tells what, how and why.

EDITORIAL NOTICE.

The news issues of the Street Railway Journal are devoted primarily to the publication of street railway news and current happenings related to street railway interests. All information regarding changes of officers, new equipments, extensions, financial changes and new enterprises will be greatly appreciated for use in its columns.

All matter intended for publication must be received at our office not later than Wednesday morning of each week in order to secure insertion in the current issue.

A Visit to the New Manhattan Power Station

On Saturday, Sept. 15, the Brooklyn Engineers' Club had a pleasant outing in the form of an inspection tour to the Manhattan Railway Company's power house, which is now in course of construction at Seventy-Fourth Street and East River, New York. The excursion was enjoyed by about thirty members of the club, the engineers in charge of the work giving them every facility to inspect the details of the construction. The genial secretary of the club, A. J. Provost, Jr., succeeded admirably in preventing the visitors from missing any of the interesting features, and the club is to be congratulated for having so able a guiding spirit.

A Serious Collision Near New York

About forty persons were injured in a head-on collision between two cars of the Yonkers Railroad, of Yonkers, N. Y., on Sept. 15. The collision occurred on the Yonkers Avenue line, about half a mile east of the Empire City Trotting Track and at the foot of Valentine hill. Both cars were filled with passengers—one coming from the race track, the other going to the track. Car No. 215, the down car, left the race track for Yonkers at about ten minutes to 6 o'clock, and proceeded to the Kimball Avenue switch without incident. The next car to be passed was on the Napperhan and Yonkers Avenues switch, and after proceeding for some distance car No. 143 suddenly hove in sight. Power was reversed and the brakes applied, but too late. The cars came together with a crash. Both were derailed and completely wrecked.

New Air Cars for Twenty-Third Street, New York

Two of the new air cars of the Compressed Air Company, of New York, were placed in service on the Twenty-Third Street line of the Metropolitan Street Railway Company, of New York, on Sept. 15. The line extends across town from the East to the North rivers, and the first car started with a starting pressure of 1950 lbs. After making two round trips the car returned to the charging station with 950 lbs. remaining, showing that when the cars are fully down to their bearings and limbered up they can easily make additional trips with one charge of air. The second car also made two trips. Both are now running regularly. The air is furnished by a small compressor, as it is not intended to start up the large compressor until more than ten cars are in actual service on Twenty-Third Street. As soon as fifteen cars are in service they will be transferred to Twenty-Eighth and Twenty-Ninth Street line, and the entire service on that line will then be performed by air cars. The old cars, which were used on Twenty-Eighth and Twenty-Ninth Street line, aside from their other objections, were only able to make one trip across town, starting with a higher initial pressure than is used in the new cars.

The Chicago Tunnel Question

James B. Galloway has submitted plans to the Chicago Street Railway Commission for the construction of a set of seven single tunnels under the river to replace those now being used by the car lines. The city is now trying to force the companies to lower the present tunnels, and the companies have taken the matter to the Circuit Court, claiming that the city has no jurisdiction in the matter. The city claims that the present tunnels are an obstruction, but this is denied by the companies. It is estimated that new tunnels could be built by Mr. Galloway's plans at a cost of $1,500,000, and that they would obviate the necessity of lowering the present tunnels and would add to the efficiency of the street railway systems, while making La Salle Street a connecting link between the north and south side boulevards. It is advocated that the city build the tunnels. For the north side there are to be two tunnels for south-bound cars, in Wells and Clark streets, and one in Dearborn Street for north-bound cars, using Monroe Street, as now, for the southern boundary of the loop. The La Salle Street tunnel could be removed and a wide bascule bridge be placed over the river. It is further proposed that the street car tracks be taken up and the street made a boulevard from Jackson Boulevard to Lincoln Park. For the west side, east-bound tunnels would be in Van Buren and Madison streets, and west-bound tunnels in Adams and Washington streets; the temporary return of the Madison Street cars being through the Adams Street tunnel during the reconstruction of the old Washington Street tunnel. The places of approach would then provide outlets near the Union and Northwestern railway stations. The tunnels are to be 15 ft. in diameter, and are to be put 30 ft. below datum and with grades of 7.5 per cent, 8 per cent and 9.5 per cent.

The Convention of the New York Street Railway Association

The eighteenth annual meeting of the Street Railway Association of the State of New York was held at Buffalo on Tuesday and Wednesday, Sept. 18 and 19, with a large attendance. When the association was called to order by President Rogers at the Iroquois Hotel Tuesday morning, over one hundred delegates responded to the roll-call. Mayor Diehl welcomed the members of the association to Buffalo, after which President Rogers responded. He then delivered his annual address, which is given, in part, below:

PRESIDENT'S ADDRESS

Before the smaller cities and towns of our State can expect any very radical improvements in their street railway construction, or can render the service the public demands, the law requiring the street railways to pay for pavements must be amended. Much has been said and written upon this subject, and I believe that the public is aware of the unfair and unjust burden that is being placed on the small roads in these localities. It is the duty of the State of New York to rectify this serious error, which, in nearly every instance, means in the end a receiver, as has been illustrated throughout the State. The smaller cities try to impose the same burdens on street railways as do the larger cities upon their roads. What might not be a heavy burden to the one means destruction to the other. The suggestion has been made that each municipal body granting a franchise should be authorized by the statute to make a special contract with the applying corporation for either the construction or maintenance of pavements in the whole or different sections of the locality. The lack of elasticity in the present statute militates strongly against the best requirements of small cities for the joint interests of the roads and the public.

The Railroad Commissioners' report of 1899 shows that there are ninety-four electric roads in this State, and forty-one show a deficit while only fourteen declared a dividend. Of the latter, four were in the smaller cities, being operated partly as interurban roads. This report also shows a gain in the receipts of the surface roads over the previous year in this State of 7 1-10 per cent; also that the lines of greater New York carried 55 per cent of all the passengers in the State and their increase was 74 per cent of the total increase of the State.

It is a recognized fact that there is nothing that will more rapidly and permanently develop smaller cities than rapid transit, especially interurban service. Oftentimes the value of real estate in certain districts will advance upon the mention of an extension of a road in that direction. The people of provincial cities stand in their own light in not taking measures to have the above mentioned law changed. I am satisfied that the public is each year realizing more and more the benefits accruing from a well constructed, well equipped and carefully managed street railway in its midst.

The management of roads in the smaller cities make no mistake in taking the city authorities and the public into their confidence, appealing to their sense of justice and fairness. This course, if conscientiously and consistently followed, will result in much good. The sympathy and good-will of the people is necessary to the success of a street railway, and without it, especially in small cities, it is next to impossible to succeed.

The fate of the Ford franchise law, which was placed on the statute books two years ago, is yet to be determined. In my opinion there is but one result, and that is disappointment for the makers of the law, and the people, and dissatisfaction to the corporation which it affects. I would again call your attention to the injustice and unfairness of the law passed three years ago, taxing street surface railways 1 per cent on gross earnings, while other corporations (who are better able to pay the tax) are taxed ½ of 1 per cent. Nearly every legislator who has been consulted on the unfairness of this act admits that section 185 of the general tax law should be amended, thus leaving railway companies in the same situation as other public service corporations. It is our duty earnestly to take the matter up with the Legislature, and I believe that this serious injustice can be rectified.

Foreign street railways seem to be more fortunate than those of the United States in the matter of tax upon gross earnings. As an illustration—the British tramways are paying into the public treasury less than $600,000 annually in a formal tax on gross receipts of $25,000,000. The street railways of New York and Massachusetts alone are paying nearly $2,500,000 on gross receipts of $50,000,000.

The municipal ownership agitator is still active, but I think the fever has abated, at least it is working westward. No doubt some of these agitators are sincere and honest in their advocacy of the theory. If the craze is allowed to run its course, public opinion will in time desert it, especially after a few more illustrations of the impracticability of the theory in America under American politics. Under municipal ownership the agitator claims the wages of the men will be increased. Incidentally, perhaps, the vote of the political party then in power will also be strengthened as well as the taxpayers' bill of expense; this is a phase of the question which every American taxpayer should study. The majority of the voters are not taxpayers, hence their liberality with other people's money.

Municipalities should not be allowed to mortgage the unborn generations to produce the construction or operation of public service industries to satisfy the theorist. They should only be allowed to secure funds for such indebtedness by mortgaging the property income of the undertaking, and the franchises themselves and the mortgage should stand or fall upon such merits. Such a mortgage, of course, would be subject to foreclosure by default the same as a mortgage given by a private corporation and without recourse to the taxpayer.

If the general impracticability of the theory of municipal ownership did not condemn it, another fact would, and that is that a business made up of detail and involving such close care and attention, could not be looked after successfully or profitably by municipalities, particularly with the present incomplete system of municipal accounting.

The work that was inaugurated at our last convention at Ithaca, with the object of further promoting a spirit of loyalty and goodwill and of increasing the efficiency of employees, has resulted in much good. We should continue to educate our men in the duties they are to perform, treat them as men, and make them feel that by intelligent service and loyalty to the company they can better their position and gain promotion. This is important to the life and development of street railways. Our benefit associations are important factors in accomplishing this end. I understand that nearly every road in the State has its benefit association and that each has the hearty support of its respective road; in fact, this department is given quite as close attention as any other department connected with the service. The success of these associations is largely due to the intelligence of the employees who are operating our roads, the solid principles on which they are organized, and the opportunity it gives the management and the men to help one another. The many benefits derived from these organizations are a just inheritance, not a charity.

One-third of the invested wealth of the civilized nations is today invested in railways, and not an inconsiderable portion of that investment should be protected. It goes without saying that a perpetual or long-term franchise is better suited for investors than a short-term franchise, which can be annulled at will. Under a long-term franchise, better construction and improvements can be made which will inure to the comfort and convenience of the traveling public. In this State a large number of the roads have long term, and in some instances perpetual franchises, but on account of the heavy burdens imposed by taxation and the municipalities and State requirements, only a small portion of the roads are paying a dividend, and of these a large number are in Greater New York.

In financiering a street railway, as large a portion of the bonds and stocks as possible should be disposed of to local investors, thereby insuring a local co-operation and interest that cannot fail to redound to the benefit of all concerned. It is very important for street railways to have as large a number of local stockholders as possible, thereby creating a common interest with the citizens in our properties. We must be frank and open with investors, which will result in securing and retaining the confidence and increasing the holdings and the number of holders.

A recent decision of the Appellate Court of this State and the decision of the lower courts in other States to the effect that cars designed to carry freight only are permissible on street railways is a decided gain for the roads which elect to engage in the freight and express business, which is becoming a matter of more importance every day, especially to interurban roads. Some very important express companies, I understand, are now in existence, operating entirely on trolley roads. The advantages of these companies in part consist of their quick service and ability to take freight from the farmer's door and transfer it through the various streets of the cities at frequent intervals. Freight and express service on the trolley roads seems to meet a much needed public requirement.

Stimulated pleasure riding and the establishment of parks and entertainments have proved to be a move in the right direction, and nearly all the roads have institutions of this kind, particularly those who are not confronted with the problem of providing efficient means of transportation for the large number who desire to ride.

There is no question but that the transfer privilege (with which we have been too generous) is being abused. There is no law obliging the roads of the State, excepting those recently built, to give transfers. If the transfer system of large roads could be so arranged that transfers were given only at points of any conse-

quence and to the passengers traveling in one general direction, and if it could be arranged that passengers could not secure transfers returning in the same general direction from which they came, it might eliminate some of the abuse.

The important suggestion that has been made, that the points of issuance of transfers should be limited and designated by the Board of Railroad Commissioners, will commend itself to all operating men.

Street railways have not, in my opinion, anything to fear from the competition of the horseless carriage. This vehicle may be used for carriage and cab purposes to some extent. The "loco" or "auto" is still the fad, however. We hope that the many inventors now working on the various vapor motors for the "auto" may produce something that will prove practicable and economical for street railway operation.

Much has been accomplished in the standardization of our accounts which will work out untold benefit to the roads; besides strengthening our securities, it will give confidence to the public, and afford us material for comparison. Our track system is also working out its own standard.

It is to be hoped that we will soon reach a standard in a permanent type of mechanical power, and it will be no longer necessary to discard costly apparatus because improvements have displaced them. As to equipment and rolling stock, we do not seem to accomplish much in standardization, except on the larger roads. This result is due to a combination of circumstances which I will not attempt to enumerate. If we could standardize our equipment it would be a saving in many directions.

The distance from New York to Boston of 257 miles is covered by electric railways, excepting about 52 miles, which illustrates the fact that street railways will soon connect the larger cities as well as the smaller ones. A story of a trip by trolley between New York and Boston has been recently published which is very interesting, and suggests that even a broader field than heretofore will be found for the trolley road.

It would be an oversight if some allusion were not made at this time to the wonderful development of the street railways of the State during the past year, particularly in cities of the first class. As a matter of fact, the improvement of the street railway service of New York, Brooklyn and Buffalo during the past twelve months has been almost startling in its character, and is an object lesson in rapid transit for the country at large.

Since the meeting of last year, the situation in the City of New York has expanded and developed with giant strides. The Metropolitan Street Railway company has pushed with great vigor the completion of the very important power house at Ninety-Sixth Street and East River. This plant has been laid out with reference to the interests of the entire street railway situation in the city. Its boiler capacity is remarkable, while the operation of the nine enormous vertical compound engines, remarkable for their accuracy and delicacy of operation, is a continuously interesting and instructive study. The plant, which will be completed during the coming year, is of primary importance in being the first station in the city of New York constructed for the development and distribution of the alternating current and the use of sub-stations with rotary converters and transformers.

The city is on the eve of another important improvement, to wit: The substitution of the electric current on about 25 miles of road now operated by cable. This work, involving millions of dollars in street construction and new equipment, is being pressed to a speedy completion and will undoubtedly result in great benefit to the traveling public. The passing of the cable roads brings to our attention the short life of the system. In the early '90's it was considered the motive power of the age, but a decade has seen its extinction for the movement of cars in cities. While the character of cable service has been raised to a high degree of perfection, the lack of elasticity in the convenient operation of car lines has been the chief cause for its extinction. The greater advantages in methods of operation furnished by electrically-propelled cars, or self-contained motors, will always commend these latter forms of operation to the minds of operating men.

The proposition of operating short crosstown lines in New York City is still subject to investigation and research. The great cost of the underground electrical construction, with its attendant expenditures for the removal of pipes and other property not belonging to the railway company, precludes the use of this character of equipment upon such short lines. At the date of my last address, the use of compressed air as a motive power was in apparently practical operation. While the type of motor then in use has not proved altogether successful, the test which is now being carried on by use of the Hardie motor will undoubtedly meet the requirements demanded of it.

Among the more important developments of the present day is the operation of the Thirty-Fourth Street crosstown lines by storage battery. The complete equipment of that line by that form of motor, and its actual operation as a system and not as an experiment, will demonstrate finally the desirability of the use of batteries as motors. The preliminary operations, as I am advised, are altogether successful, and there seems little reason to doubt that the operation during the winter will demonstrate the perfection of the system. For many years but little attention has been given to the improvement of storage batteries for street car operation. The great extension, however, of the use of these motors for cab service and small delivery wagons in this city has proved the desirability and usefulness of the storage battery, and called attention to its adaptability for the operation of railway lines requiring the use of self-propelled cars.

With the extension of railway systems in the city of New York necessarily follows the greater increase in travel. For the last fiscal year the returns of the Metropolitan Company show that 452,761,158 passengers have availed themselves of the right to ride on the company's lines, of which 297,254,580 were cash passengers, with 155,506,578 transfer passengers. These returns show an increase over the preceding years of 61,000,000 passengers carried, of which 34,000,000 were cash passengers and 27,000,000 were transfers.

There is no better illustration of what a street railway system, properly conducted and operated, can do for a large city than is manifested by the Brooklyn Rapid Transit Company. They have acquired nearly all of the surface railways of the city and thoroughly re-equipped same. They control and operate all of the elevated railways of the city, the larger portion of which they have equipped with the third-rail electric system. They have also acquired and electrically equipped some steam railroads leading to Coney Island, all of which are operated in conjunction and under one management.

Owing to the liberal policy adopted by the surface railways of Brooklyn, the bridge fare has been dispensed with, as far as car riders are concerned. You can now take a car at the New York City Hall and go to almost any portion of Brooklyn for 5 cents. The excellent transportation facilities with which Brooklyn is provided have done much toward developing the numerous and rapidly growing suburban localities of that city.

The advancement and improvement of the excellent street railways of Buffalo and vicinity will undoubtedly be exhibited in a practical way by our host, the International Traction Company. I have no doubt you will all derive great pleasure from the general inspection of and the ride over the several lines which go to make up the splendid system for which the locality is so justly celebrated.

During the past year the record of this association has been one of progress and improvement. The fact that it is established on a sound basis is shown by our meetings which I am pleased to say are so generally attended by the street railway people of the State who are seriously studying the question of transportation and how they can improve its condition.

Papers were then read on "Accidents on Street Railways; Methods Employed in Handling Same and Preparing for Trial," by D. W. Patterson, of the legal department, Metropolitan Street Railway Company, New York; "How Can We Increase the Efficiency of Our Employees?" by E. G. Connette, vice-president and general manager of the Syracuse Rapid Transit Railway Company, of Syracuse; "Railway Power Transmission," by J. H. Armstrong, of the General Electric Company, Schenectady, and "The Use of Storage Batteries on Small Roads," by B. B. Nostrand, Jr., president of the Peekskill Electric Light and Power Company, of Peekskill. These papers are published elsewhere in this issue.

At the afternoon session papers were read by Superintendent Thomas Henning, of the Buffalo power house; Vice-President T. J. Nicholl, of the Rochester Railway Company, and Prof. Norris, of Cornell University. After the close of this session the delegates were taken to the Cold Spring power house of the Buffalo Railway Company. After thoroughly inspecting this plant they visited the Pan-American Exposition grounds at the special invitation of Director-General Buchanan. Much interest was expressed in the buildings for this important fair, which have now advanced quite far, and at the extent of the proposed exposition.

The annual banquet was held Tuesday evening at the Ellicott Club. There was an attendance of about 200. Mr. Rogers presided and Mr. Ely, president of the International Traction Company, was toastmaster. The gentlemen who occupied seats at the principal table were the Hon. W. Caryl Ely, H. H. Vreeland, the Hon. S. Fred Nixon, M. Nussbaum, P. F. Trainer, H. H. Littell, Alexander J. Porter, T. F. Thomson, the Hon. William I. Buchanan, W. B. Rankine, Herbert P. Bissell, the Hon. John G. Milburn, Charles J. Bissell, Henry A. Robinson, Bert Van Horne, Tracy Rogers, the Hon. Conrad Diehl, Henry M. Watson, Charles W. Wasson, James H. McGraw and Otis W. Cutler. The

speakers included Mayor Diehl, President Milburn and Director-General Buchanan, of the Pan-American Exposition; Charles Bissell, W. B. Rankine, Herbert B. Bissell, S. Fred Nixon and H. H. Vreeland.

A full report of the proceedings of the second day, the remaining papers and the discussions on the papers presented will be published next week. There were a number of exhibits, as follows:

EXHIBITORS AT THE CONVENTION

The Couch & Seeley Company, of Boston, made a very creditable exhibit, showing the iron box telephone and other telephonic apparatus manufactured by it for street railway service.

The G. P. Magann Air-Brake Company, of Detroit, had an equipment on one of the Main Street cars, which was in continual operation. It proved a most practical method of illustrating the air storage system of this company.

The National Carbon Company, of Cleveland, had on exhibition samples of its new process carbon brushes, also battery carbons and various carbon specialties.

The Central Brake Shoe Company, of Buffalo, N. Y., and Reading, Pa., showed samples of the well known Diamond S. brake shoes.

The Edison-Johnson Electrical Manufacturing Company, of New York, exhibited its new type of trolley hooks, which are guaranteed to keep the trolley from leaving the wire.

The Cutter Company, of Philadelphia, showed one of its popular I. T. E switches.

The Bierbaum & Merrick Metal Company, Buffalo, had on exhibition samples of the "Ideal" trolley wheel. This wheel is very novel in its construction, and seems to be all that its name implies. Judging from the repeated orders received the wheel is fast finding favor with street railway managers. The company also showed samples of car bearings made from Lumen bronze, another specialty of this company.

The R. Bliss Manufacturing Company, Pawtucket, R. I., showed a handsome model of its patent safety car gate.

The Speer Carbon Company, of St. Mary's, Pa., made quite a display of its well known carbon brushes.

The Morris Electric Company, New York, had an extensive exhibit of the goods manufactured by the company, and the specialties which it handles. It consisted of rail-bonds of all types and for all purposes, pneumatic rail-bond and wire-joint compressors, Monarch fare registers, National electric car heaters, the Potomac terra cotta conduit, etc.

The Keystone Electric Company, of Philadelphia, showed various types of its well known voltmeters and ammeters.

Chisholm & Moore, of Cleveland, had on exhibition various sections of the American Standard rail-joints, tie-plates, etc., and also a fine collection of India ink drawings of traveling cranes, chain hoists and other power house machinery made by this company.

The Atlas Railway Supply Company, Chicago, showed various samples of its joints for all types of rails, also a combined rail-brace and tie-plate.

The Gold Street Car Heating Company, New York, exhibited samples of the Gold improved electric heaters, panel pattern, for cars with longitudinal seats and standard pattern for cross-seated cars.

The Weber Rail-Joint Manufacturing Company, New York, showed handsome samples of the Weber rail-joint, as applied to both T and girder rail.

Harold P. Brown, New York, made a display of the Edison-Brown plastic bonds, showing the various types and applications of these bonds.

J. W. Gorman, Boston, showed a fine collection of large and handsome photographs, showing scenes in many of the beautiful street railway parks in New York and New England, most of which are embraced in his park circuit of attractions.

The Consolidated Car Heating Company, Albany, exhibited some of its various types of electric car heaters.

The Hale & Kilburn Manufacturing Company, Philadelphia, had samples of its cross-seats on exhibition.

The Compound Magnet Brake was shown and operated on one of the cars of the Buffalo Street Railway. The equipment was in charge of P. H. Alexander, of New York.

The H. W. Johns Company, New York, showed samples of the line material and other specialties manufactured by it.

Mayer & England, Philadelphia, exhibited several types of the "protected" rail-bond, and samples of some of the specialties made or handled by them.

Giles S. Allison, of New York, had on exhibition models of the new steel sectional pole for trolley-wire construction, known as the electric tripartite steel pole, and for which he is the general sales agent. Much interest was taken by the delegates in the models of these poles, and several trial orders were placed. A number of roads on which poles of this kind are installed were represented at the convention, and the expressions in favor of the pole were quite pronounced.

How Can We Increase the Efficiency of Employees?*

BY E. G. CONNETTE

It is obvious that the interest of the employer is in the most faithful, intelligent and willing workmanship; the problem is, what method shall we pursue to secure a high standard of efficient employees. With skilled and willing men we are better able to effect a satisfactory service and more economical operation and a successful management of the interests entrusted to our care.

We will, therefore, discuss the subject upon the hypothesis that to secure an increase in the efficiency of employees, that they must be kindly treated, their willing co-operation must be secured and methods adopted for their education in the service.

I.—KIND TREATMENT

The employer has not discharged his duty in paying a laborer; he owes him also courtesy and friendly respect as a man. Men are naturally susceptible of kind treatment; even the wild instincts of barbaric races have been subdued by the kindness, forbearance and Christian charity of our missionaries. A dog that is kindly treated will wag his tail and give his master a cheerful welcome, while the cur that is beaten and knocked about will snap and snarl and run off with his tail between his legs when his master approaches. All men have more or less pride, no matter what their position may be, and directing men in their work should be done in such a manner as not to humiliate them, but in such a way that they will obey orders cheerfully and manifest an interest which shows, that to obey orders is a pleasure as well as a duty. Sometimes foremen who are placed in charge of departments are incapable of properly directing the men under them, by being abusive, overbearing and humiliating, due in some cases to ignorance and incapacity, but generally by an abnormal case of "swelled head." Some men think that they can make their orders more effective if accompanied with profane language, but, in the opinion of the writer, this only tends to reduce the efficiency, as men who are abused, oppressed, or treated unkindly will resent it in one way or another—this is only natural. Men show their noble qualities—courage, fairness, generosity—to those who treat them well and expect their best. This is true of the horses and cattle, which do their best for the masters who treat them most kindly. Instructions or orders issued in a kind and courteous manner, at the same time with a firm and positive accent, that carries with it respect and loyalty, will attain a quicker and more cheerful obedience, and result in a more contented and satisfied condition of mind, and will induce an earnest desire to comply with the wishes of those in authority. The indulgence of a desire to treat employees kindly should not, however, extend to familiarity, as familiarity may breed contempt and a lack of respect of those in authority; and there should be no relaxation of discipline, but it should be administered with justice and right, always giving the accused the benefit of any doubt which may exist and a penalty fixed which is commensurate with the offense, but only after a full and thorough investigation. Decisions in haste, by those in authority, during spasms of wrath when a breach of discipline occurs, is liable to impress upon employees that "might makes right." Our vocabulary also should contain words of praise and encouragement as well as reproof. Reward of merit is also an incentive to increased efficiency in the service.

II.—CO-OPERATION

A Roman Emperor said: "We are made for co-operation like feet, like hands, like eyelids." It is not right to treat men like machines or as rivals, but we should work together in order to secure an orderly and prosperous state; this is essential to success in all large enterprises—hearty co-operation with both great and small, from the janitor to the manager. A co-operation of brains and brawn—brains to plan and brawn to execute—with that regard and esteem existing between the two that makes an irresistible foe to failure and insures success in every enterprise. A general may direct, but his success depends upon the fighting qualities of his soldiers and the execution of his orders. A hearty, cheerful co-operation between the men and the officers and between the various departments is a large factor in bringing a high state of efficiency among the men.

* Paper read before the New York State Street Railway Association Sept. 18, 1900.

III.—EDUCATION

When by kind and fair treatment the respect and confidence of the men have been secured to such an extent that there is a hearty and cheerful co-operation, the men are susceptible of being educated, and while all men are not born with the same number of talents, still with a state of good feeling existing, they are capable of absorbing instructions and becoming educated to the extent of their capacity; and when men are willing to learn and increase in knowledge, sometimes those who are not even gifted with ten talents become more proficient by reason of their willing disposition and diligent application than others who have a greater capacity, but from a lack of co-operation, kindly feeling and lack of interest, they are unwilling to improve the efficiency of their position. When men are in the proper state to be educated, every possible means should be provided to instruct them in their particular position; but the same method should be observed in giving instructions as is observed in any other method of education. Instructive paragraphs, issued either in bulletin form or printed, should be short, but comprehensive; no unnecessary words or large, incomprehensive phrases used where small words and simple phrases will answer the purpose.

By a concise and simple, yet comprehensive, system of instructions, carefully arranged and administered in digestive doses, it will increase the efficiency of men in their several vocations, and will result in better service, both to the company and to the public, and a more economical operation.

"Storage Battery—Its Use on Small Roads"*

BY B. B. VAN NOSTRAND

The application of storage batteries to the generating system of large electric roads has been described by many engineers in a variety of ways, so that an impression has been left upon many minds that it is only with these larger systems that the battery scheme is feasible. This idea is incorrect, and I think that the following description of the equipment and operation of the Peekskill Lighting & Railroad Company will bear me out in the statement. In the description of this road we shall see conditions that apply in a general way to most small lines.

This road was placed in operation in June, 1899, since which time it has been running without any interruption except momentary stops caused by the circuit breakers flying out. Beginning at the station of the New York Central Railroad, which is at the western edge of the town, near the Hudson River, the road proceeds in a practically straight line through the center of the town and on to Lake Mohegan—a total distance of 4¾ miles. The road is an exceptionally hilly one, in fact the fairly level portions are the exception, and are never more than 1600 ft. long. Beginning at the New York station terminus, the road, as far as grades are concerned, is about as follows: Starting into town, there is 1000 ft. of 7½ per cent grade—with a small portion (say 20 ft.), where it reaches 9 per cent. For a distance of about 4000 ft. beyond this, there is a gradual grade, varying from 5½ per cent to 2 per cent, terminated by 300 ft., of 5½ per cent to 7½ per cent. At the top of this is a short level, leading into a 2000-ft. 2 per cent incline, followed by 1600 ft., varying from 4¼ per cent to 8¾ per cent, which is in turn followed by 2009 ft. of 3¾ per cent up-grade. There is after this a depression, represented by 1400 ft. of down-grade, varying from 6.8 per cent to nothing, which, after passing into a short level, rises by 1400 ft. up-grade, with a maximum of 4.6 per cent, to another short level. Then follows another down-grade of about 1800 ft., varying between 8 per cent and 2 per cent. This is followed by 1600 ft. of level—terminated by 300 ft. of 8 per cent. After this is 1000 ft. of level, passing into a short down-grade of 6 per cent, 1300 ft. of level is after this, passing into 2000 ft. of 7½ per cent. The final portion to the end of the road is about 800 ft. level.

This entire line of single track, with four turnouts, 56-lb. T-rails are used throughout, these being laid in the usual manner.

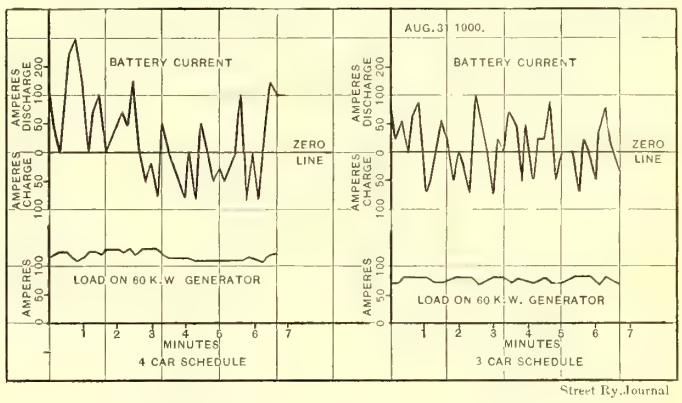
There is a single-track branch 4000 ft. long, extending from the New York Central station north to the State Camp Ferry. This operates but one month of the year, at which time two cars are in service.

The overhead construction of the system is simple—consisting of 00 trolley throughout, with 0000 feeder, extending to within ½ mile of the lake end and 1000 ft. from the station end. The branch has no feeder. The 0000 feeder is tapped at regular distances throughout its length.

The apparatus for operating the road consists of one 60-kw Edison bipolar 575-volt, 880-r. p. m. generator, belted to a horizontal 13-in. x 12-in. Armington & Sims simple engine, the horsepower of which is about 100, at 275 r. p. m. Belted to this same engine, in tandem with the dynamo, is a four-pole differential booster, which is used to render the charging and discharging of the battery automatic.

There is another unit consisting of a Westinghouse 120-kw multipolar 625-r. p. m. generator, belted to a vertical 14-in. and 24-in. x 14-in. Westinghouse compound engine of 200-hp capacity. It may be added here that this generator is rarely used, and that only when the road is unusually heavy—such as occur on holidays and warm Sunday afternoons. The same engine which operates this generator is also belted to one of the alternators for incandescent lighting. It may be well to note that in addition to the above engines there are three other engines which operate the remaining light machines. These, of course, have nothing to do with the railway system. In the boiler room are three 80-hp and 100-hp horizontal return tubular boilers, carrying steam at 105 lbs. pressure. During the summer months two of the 80-hp boilers are sufficient to run the entire plant—though three become necessary in winter.

The battery, which is in the simple wooden shed next the boiler



No. 1 No. 2

room, consists of 262 type-F-9 chloride accumulator cells. Each cell is comprised of nine plates, 10½ ins. square, suspended in glass jars of sufficient size to enable the capacity to be increased in future by the addition of more plates. Each cell is mounted upon a wooden tray, filled with sand, to ensure an even foundation for the jar. These trays rest in turn upon glass insulators, supported by a wooden battery rack. On full charge the battery has a maximum rated capacity of 160 amps. for short periods. As a matter of fact, however, it is often called upon to discharge at a considerably higher rate than this, 250 amps. being called for momentarily.

During the summer season three cars are run from 6 a. m. to 12 m. Two of these run through Peekskill as far as the car house at the eastern edge of the town. The other car runs through the town and on to Lake Mohegan. This gives a twelve-minute schedule in town, and forty-eight minutes through to the lake. In the afternoon and evening four cars are run, giving a twelve-minute schedule in town, and twenty-four minutes through to the lake. On holidays, etc., five cars are run, all going through—thus maintaining a twelve-minute schedule throughout the run.

Having gained a fair idea of the nature of the system, we will pass to the results obtained in the station.

The point of first importance is the remarkable constancy of the load upon the generator, and the correlated fact that the 60-kw machine is all that is necessary to operate the road, except when running the five-car schedule. The curve marked No. 1, in the engraving, will explain this. This shows the results of ten-second readings, taken upon the battery and generator during a short portion of a four-car run. The total line current is, of course, the summation of these two. It is seen that this total current fluctuates between 25 amps. and 310 amps., and that the generator runs along at practically full and constant load—the battery assuming the fluctuations above and below this. Curve No. 2 shows the same results for a three-car run. Here the average or generator load is lower (about 75 amps.), and the line fluctuations from 0 amps. to 170 amps. The practical good of this is evident. It means that a 60-kw machine is running instead of 180 kw, which would be required were the battery not in service. In other words, although the load fluctuates from almost nothing to 180 kw, the average is in the neighborhood of 60 kw, and it is this average only which falls upon the generator and engine. The remarkable evenness of the load upon the generator produced by the operation of a storage battery is shown very nicely by the fact that we are operating our 120-kw railway machine and one of the alternators for our electric lights from the same engine. Ordinarily this would produce a very serious flickering in the lights, but in our

* Paper read before the New York State Street Railway Association Sept. 18, 1900.

case it is impossible to detect the slightest change in the brilliancy of the lamps, although the railway may be fluctuating between its widest limits. I have not had an opportunity to test the coal saving produced by this arrangement, but I am confident from my observations that it is sufficient to pay a good return upon the battery investment over and above the interest and depreciation charges.

The increased economy of a small unit operating at a full and constant load above that of one three times the size, but doing the same work under highly fluctuating conditions, is such as to warrant this assumption.

It would be difficult to increase the simplicity of operation in this plant. After the original adjustment, the apparatus has worked together without the slightest difficulty. We have a generating unit operating under electric lighting conditions, due to the fact that the battery removes from the systems all sudden overloads, and the strain thus removed from the minds of those in charge is in its effect almost as valuable as this latter consideration.

In other ways the battery is valuable. A great many times it has been necessary to shut down the small engine suddenly from some mishap. During the eight or ten minutes necessary to get the other unit into operation the battery has carried the entire load.

Then, too, it is often desirable to run a car for some special occasion very late at night. At such times the generator is shut down and the battery thrown across the line.

In conclusion, I may state that the battery has given us absolutely no trouble since its installation, and the daily labor for its proper care does not average more than one-half hour. In fact about all the work required is that of taking voltmeter and hydrometer readings upon the individual cells once each week.

Accidents and the Methods Employed in Handling Them*

BY D. W. PATTERSON

It is an old saying that accidents will happen in the best regulated families; likewise is it true that accidents will happen on the best regulated street railways. It is not in the happening of accidents or the facts surrounding them that the real struggle in a negligence case takes place, and in this human nature is well depicted, and often much more care is taken in the preparation of the case from the standpoint of injuries than it is from the standpoint of proving how the accident happened, and many an attorney's dreams of large fees have been frustrated because of his zeal in proving the seriousness of the injuries and neglecting definite information as to how the accident occurred. It is interesting to notice the development of specialists in the law and in medicine, resulting from the possibilities of large fees from such a class of cases. A few illustrations may not be without interest: In one case a man received a slight injury in the location of his spine. There was little question but that the accident occurred in such a manner that the plaintiff was entitled to something for his injuries, but knowing that they were entitled to something they at once became grasping. They not only wanted enough to compensate the plaintiff for his injuries, but the lawyers evidently wanted enough out of it on which to retire. So they procured a large array of medical experts and engaged special counsel, and from the bruise was evolved the most fearful human afflictions. The plaintiff was carried into court, and after this pitiful exhibition his experts went on the stand and testified that he was suffering from amyotrophic lateral spinal sclerosis implicating the motor nuclei of the medulla oblongata. The defendant also produced its experts, and at the conclusion of the trial, which lasted for six days, the jury were so impressed with the falsity of the plaintiff's claim that they brought in a clear verdict in favor of the defendant.

It is such accidents as the one just referred to that are most dreaded by a defendant; where the injury is visible and definite; where an arm is broken or where a leg is amputated, no matter how serious the physical disability may be, there is less danger of large verdicts than where there is opportunity from a slight injury, or mere bruise, to build up a clever claim of a nervous disorder. Accident cases divide themselves logically into three classes:

First.—Where the plaintiff wilfully and systematically perpetrates a fraud.

Second.—Where the plaintiffs themselves are the sufferers of their own delusions.

Third.—The comparatively small number of cases where the nervous conditions claimed are real.

As an illustration of the first, I remember a case where a man had his arm injured, and his attorney asked him how high he could raise his arm, and he indicated a very marked impairment of its use. The defendant's lawyer, after diverting the plaintiff's mind from this subject for a few moments, suddenly said: "How high could you raise your arm before the accident?" and immediately the plaintiff, taken unawares, raised it high above his head. The defendant's attorney asked no other questions, and, amid the laughter of the court room and the amusement of the jurors, the discomfited plaintiff left the stand. In a similar case, a young girl was injured, and the trial not taking place until two or three years after the accident, she claimed that she had been bedridden during the whole time, that her health had been destroyed and that she was absolutely incapacitated from physical exercise of any kind. Nevertheless, upon the trial, while plaintiff was in the court room on a stretcher, the defendant showed a series of photographs in which the plaintiff was depicted hanging out clothes, rowing a boat, climbing mountains and performing other feats requiring physical strength and agility. After she had displayed her pitiful condition and her awful suffering, these photographs were shown to her one by one by the defendant's attorneys, and with flushed face she was compelled to admit that these were correct photographs taken of her since the accident, and that they correctly portrayed her in the acts depicted. These cases illustrate the first class, namely, where all the parties concerned in the plaintiff's case are attempting to perpetrate a gross fraud. It is this class of cases more than any other that test the ability to obtain justice and fair dealing, because with unscrupulous persons, fraud and simulation are so easy and the way of unearthing it so difficult that there is every inducement to cover up the tracks as much as possible, and experience has taught such persons that they are almost beyond the clutch of the criminal law, for while evidence may be procured which would satisfy any reasonable man that fraud and deceit has been committed, it is very difficult to fasten it upon a single individual for the purpose of securing a criminal conviction. But in railways, as in all great enterprises, it is the care which is taken with the apparently minor details which brings present success and gives assurance of future stability, and it is in this case for detail that such cases as these are ferreted out. So that from the moment of an accident until the time it is finally disposed of it receives the closest investigation and preparation.

The second class of cases, so far as the results before a jury are concerned, are as disastrous to defendant as though the injuries were real. They are known to the medical fraternity as cases of hysteria. They result from mental aberrations and not from physical injuries. Remarkable cases of this nature are not uncommon. There is a thoroughly authenticated case in which a person imagined that she was blind, although there was absolutely no defect in any functional part of the eye. Other cases are recorded of where a person thought he was dumb, and one of nervous temperament often imagines that he or she has paralysis or some kindred ailment, and until the mental condition again assumes its normal state for all practical purposes the patient is as helpless as though the injury or disease were real. But, the remarkable part about these cases is that oftentimes the imaginary affliction leaves instantly, as the result of a sudden shock or of intense feeling. But it is of little satisfaction to the defendant to find that after a verdict of $10,000, $15,000 or $20,000 for such imaginary ills that the plaintiff suddenly recovers.

When you consider that as there is all to win and nothing to lose in this class of litigation, it is not surprising with all the chances in favor of the individual and against the railway corporation, that a person who suffers real or imaginary injury from a railway accident very rarely fails to demand compensation from the company responsible, and if they are not responsible they are made so by the testimony of relatives or friends who "happened" in the neighborhood just in time to see it all. Mr. Lawrence Godkin, in Hamilton's System of Legal Medicine, states: "Probably half the jury cases in the courts of the State of New York alone in any one year are actions for personal injuries resulting from alleged negligence." This seems to be not only true, but, as everyone in the legal profession seems to be attracted to accident litigation at some time or other, it is increasing with alarming rapidity. For instance, during the year from October to June, 1895, the law department of the Metropolitan system tried about fifty cases in the county of New York. As against this it tried 233 cases involving $2,500,000 during the year ending June, 1900, and the claims presented for adjustment have increased proportionately. Again, in 1895, there were no more than 500 actions pending against the company, while at the present time (excluding the new Third Avenue acquisition and its leased lines) there are about 1929 litigants, demanding $16,000,000, awaiting

* Paper read before the New York State Street Railway Association Sept. 18, 1900.

trial. These figures indicate an increase entirely out of proportion to the number of accidents. What has done more than anything else to foster and increase accident litigation is the protection afforded attorneys by statutes in the enforcement and collection of contingent fees.

The attorney's fees in negligence cases are so large and the possibilities so great that there has been a systematic effort on the part of lawyers interested in this class of cases to procure legislation furthering their interests, and as this is a matter which has recently been before the Legislature and been defeated through our executive, it may not be amiss to refer to it here.

When a person is injured, no matter when, where or how, he is immediately deluged with pamphlets and cards and personal interviews by agents and runners termed in common parlance, "ambulance chasers," who solicit the injured person as a client for this, that or the other attorney. Oftentimes the first news a wife has of her husband's injury is from one of these lawyers coming to solicit her patronage and oftentimes the last person that a dying man gazes upon is the agent or runner of some of these lawyers. When one is successful in making an unfortunate victim of an accident his client, the agreement is at once presented, providing that the attorney shall get a percentage of the recovery together with all costs and disbursements and the percentage most usually inserted is 50 per cent. Long ago the influence of these attorneys was such as to secure legislation protecting such contracts and preventing the defendant from settling with the injured person without providing for the attorney also, but not satisfied with this, at the last session of the Legislature, a bill was passed which not only gave the attorney this lien upon his client's cause of action and which protected him against a settlement, but the new bill was directed toward absolutely prohibiting the party injured and the party causing the injury to settle their differences, and allowed the plaintiff's attorney, in case such settlement was made, to make a summary motion at Special Term and procure the same relief that he would have sought had the case been tried before a jury. As already said, the bill passed both Houses, but when it came to the Governor for signature, he withheld it and delivered the following memorandum:

"I withhold my signature from this bill because in my judgment it is thoroughly vicious. It provides that no settlement of any lawsuit shall be valid without the consent of the attorneys or without an application to the court upon notice to the attorneys. The code now provides all necessary security for an attorney in that it gives him a lien upon the cause of action. This bill would be of benefit chiefly to the very lawyers whom the honorable members of their profession least desire to see benefited—that is, to those who bring suits for damages on account of accidents and who wish to be in a position to mulct both their own clients and the defendants in case of a settlement. In its first draft the bill applied only to negligence suits. As it was passed, it applies to all suits. An unscrupulous attorney might turn it to his advantage by bringing a blackmailing suit at the eve of any great commercial or railway consolidation, when it would be in his power to hold up a settlement involving great sums of money. In short, the possibilities for fraud which are afforded by this bill are so numerous that it is not entitled to any consideration."

The unconscionable contract alluded to also specifies that the plaintiff is to bear all costs and disbursements. These two words have a very broad and comprehensive meaning when used by attorneys. Under it, the plaintiff's attorneys will place all expenses incurred in the preparation and trial, and as it is beneath him to itemize, why a lump sum is named, and as lawyers never have been noted for the correctness of their accounts, it may be confidently said that these disbursements are never underestimated. But the great inroad upon the plaintiff's 50 per cent of the recovery is made by his medical experts. These gentlemen are in such demand that they readily command from $150 to $250 a day, and oftentimes in the trial of a case they are required to attend parts of several days, and not infrequently to attend upon retrial of the action, and, as in the law, parts of days are never counted, so in estimating the bill for their services parts of days are ignored, and whenever called upon to appear the charge is for a day.

Is it to be wondered at that nearly every accident results in a law suit. Is it to be wondered at that to this branch of the law many are attracted whose only attributes are shrewdness and cunning. But more than this, leaving out of consideration the third parties, is it to be wondered at that the injured person is willing to accept a comparatively small amount in settlement, where such amount is paid to the person injured without any deduction for attorney's fees.

Adverting to expert testimony, mention should be made to the expert motorman. If he finds himself in the witness chair before a court room full of people there seems to be an irresistible tendency for him to attempt to show off, and this most often takes the form of claiming that he can stop a car in an incredibly short distance. It is a common occurrence if given the opportunity to testify, that he can stop a car within 5 ft. going 12 miles an hour. The highest appellate tribunal seems to have recognized the impossibility of this, for they have said that "This, upon its face, is untrue, for it takes one-half second to go 5 ft., a time not only manifestly insufficient to stop a car, but even to set the brake;" and here again the importance of having a motorman fully understand that by the question, within what distance can you stop your car, is meant not the distance a car goes after the brake is set, but means the distance the car goes from the time the object suddenly appears upon the track, and it is suggested that nothing can serve more profitably than for motormen to make practical experiments in stopping cars under similar circumstances to those under which they are called upon to testify. If this were done it would soon be appreciated that instead of stopping cars of many tons' weight within an incredibly short distance, that this distance might be doubled or even trebled, and if such experiments were conducted with sufficient frequency and publicity and made a matter of general notice, both the public from whom the jurors are drawn, and even judges who sit in review, would soon be in possession of undisputed facts, which would dispose of many cases which now serve as the means for furnishing a house for the client and a castle for the counsel. As a means of getting this matter before the public in such a way as to show its bona fide and reliability, it may be suggested that incentive be furnished to motormen by competitive prizes to be awarded for the best stopping.

It must have occurred to some that this subject of accidents has more to do with human nature than it has with the operation or management of street railways or with care or carelessness of the public. The number of actions brought to-day for personal injuries is out of all proportion to the number of actions brought in the recent past. It is not the result of a large percentage of injuries, but may be attributed largely, if not entirely, to the methods employed of appealing to human weaknesses and by arousing cupidity, throwing all else into the dim background. There is no remedy which can be suggested that is not too radical to be practiced.

The present condition is not due to chance or to the use of the term which served the subject of this paper "accident," it is the result of a system which is firmly established and is something which not cured must be endured.

Railway Power Transmission *

BY J. H. ARMSTRONG

In adopting 500 volts for railway service in the earlier days of the industry, it was thought that a sufficiently high potential had been chosen to make line losses a secondary consideration. The weight of cars and size of motors first used made it necessary to use much feeder copper in addition to the trolley wire, which, in most cases, had sufficient carrying capacity to move the cars at the extreme end of the road. The public were not very exacting in their requirements for rapid transit, and were satisfied with a service that would not be tolerated in our smallest systems of to-day.

The heavy cars, high schedule speeds and frequent stops of modern electric railway service have increased the car energy consumption to such an extent as to make the question of supplying a reasonably constant voltage over a large network one of the most important questions to be dealt with. Not only is this true of long-distant suburban roads extending 30 and 40 miles from the power house, but the large city systems have been so increased in extent by the consolidation of many small roads as to render almost inoperative the old system of 500-volt direct-current transmission from a single feeding point. The city system differs from its suburban offspring only in the more steady character of the station load, as the number of miles of track operated from a single generating station and the length of the longest feed in some of our large city systems is equal to or greater than any of our suburban roads now in operation.

The economical distribution of energy to the various units operating in a large railway system is, therefore, a question of as great importance and one to be treated along approximately the same lines in city service as in long-distant cross-country roads. This is especially true when we consider the advantages of locating a generating station in the outskirts of a large city where coal and water are available, facilities for removing ashes at hand, and

* Paper read before the New York State Street Railway Association Sept. 18, 1900.

real estate cheap, contrasted with the operation of one or more generating stations around which a growing city has spread itself, bringing up the fixed charges and operating expenses to a prohibitive limit.

In considering so large a question as the proper generation and distribution of power for railway service it will not be possible to enter into the many local details which will largely govern the system adopted in many cases, but various points common to all systems will be touched upon and some of the limitations of the various systems of operation brought out.

There are five recognized methods of distributing power which are applicable for railway work:

1.—500-volt direct-current distribution using the standard 500-volt to 600-volt direct-current railway apparatus.

2.—The operation of series-wound direct-current boosters in connection with 500-volt D. C. apparatus.

3.—The use of three-wire distribution using the track as a neutral.

4.—Alternating current distribution employing the use of alternating current generators of high potential, with step-down transformers and rotary converters suitably located.

5.—Alternating current generation and transmission with alternating current induction motors mounted upon the cars in place of the direct-current motors in the above four methods.

Excepting the last method of transmission—alternating current generation with induction motors—practically the same conditions govern the operation of large city and suburban roads. The design and operation of alternating current induction motors, however, depends entirely upon the character of the service which they are to perform, and their use will, therefore, be considered separately.

The first three methods of operation can be considered under the general head of:

DIRECT-CURRENT DISTRIBUTION

The advantages resulting from the concentration of generating apparatus in a single station have been demonstrated by the elimination of the various small generating stations when a number of small railway interests have been consolidated; operating expenses are reduced thereby partly on account of the reduced number of attendants required, less real estate carried on the books, and largely by the reduced coal consumption resulting from the more even load curve having small fluctuations.

In combining a number of 500-volt direct-current stations into one power house of their combined capacity, one of the most serious limitations of the direct-current system is immediately met with, that is, the limited area over which power can be transmitted economically with a reasonable amount of capital invested in feeder copper. If the generating station is located in the center of distribution of a closely congested district the copper investment will be comparatively small, but the price of real estate is high, and the location carries with it the probability of expensive water supply for condensing purposes and poor facilities for handling coal and ashes. The generating station also is likely to be hemmed in and little chance left for expansion, except at excessive cost of acquiring adjoining property. Hence although such a station operates at high efficiency as regards the transmission of power including interest on capital invested in copper, there are many fixed charges and operating expenses tending to bring up the total cost of generating power.

A generating station located in the heart of a city has to contend with the continual growth in the outskirts and the increased needs of heavier and more frequent car service, at what soon becomes a considerable distance from the center of distribution. It is also probable that parks and pleasure grounds will be located in the outskirts of the city at considerable distance from the power house, at which it is necessary to concentrate a large number of cars at very infrequent intervals.

The problem then becomes one of installing sufficient copper to take care of a service occurring but a few times during the year, during the remainder of which the copper investment is lying idle, or of installing series-wound boosters with a comparatively small booster feeder extending to the point of concentration of load. The booster in itself is expensive to operate, as it represents a dead loss of so many watts in the booster and feeder copper, but its operation for intermittent service of this character is fully warranted and preferable to the installation of a large amount of feeder copper carrying with it large interest charges, which are not warranted by the average traffic during the year.

The further increase in the growth of the town introduces new factors in the way of suburban connections which it is desirable to operate under the same management and from the same generating station as the city lines which feed them. The distance from a generating station centrally located for the congested traffic is, perhaps, so great as to necessitate a capital investment in feeder copper whose interest charge offsets the profits from operating such suburban connections. It is true that a direct-current generating station can be located somewhat outside the center of distribution of city load and in the direction of probable suburban extensions, but this entails a transmission of the main bulk of the load some distance to the center of distribution, resulting in a cost for power which, added to the interest on copper invested, may offset the advantages otherwise accruing to a suburban location.

Boosters may be installed for permanent operation, but, while it is true that local conditions largely govern the use of boosters, it can be generally stated that it is not economical to operate them on continuous service, while for intermittent service to help out a poorly coppered line on some special occasion they are valuable and might well be included in the apparatus of a central station.

The three-wire system has been mentioned as a possible means of power transmission for railway work, but only a general reference can be given to such a system owing to the delicate nature of balancing the two sides of the circuit, which is almost entirely a matter for local consideration. Such a system must necessarily require more care in laying out and more careful attention during operation than straight 500-volt distribution, but it may in certain cases afford sufficient advantages to warrant its adoption. In heavy work on private right of way where no objection exists to the use of two third rails, a balanced three-wire system may be used in which unbalancing is overcome, but the conditions demanding the adoption of such a system are entirely local and call for special consideration.

Most of our large city railways and practically all of our suburban roads operate their cars upon a recognized schedule, which is being adhered to more and more as the public becomes accustomed to a time table on electric roads. Where the headway is very short, say, two or three minutes or less, it is not necessary to refer to any time table, but most systems operate on a longer headway, and in such roads it is of the greatest importance that favorable conditions exist for the maintenance of a predetermined schedule. The 500-volt direct-current system fed from a single generating station centrally located affords full station potential in the congested districts where it is least needed, and minimum potential in the outskirts where the highest speed running is called for. If suburban connections are provided, the line voltage over an extended route will fall considerably from the bus-bar potential, and a schedule that can be maintained satisfactorily during normal operation becomes inoperative with such a system of distribution during hours of maximum service, owing to the considerably increased feeder drop at such periods. As the headway of cars is not so short as to interfere with the maintenance of schedule speed in the outskirts or on suburban lines, the copper investment becomes the determining factor in the maintenance of the schedule and the overload capacity of the system. Many of our suburban roads parallel steam roads and depend for their existence upon their ability to make as good time with more frequent stops as their steam competitor. The ability of the electric cars on such roads to make high schedule speed depends upon the maintenance of a good average line voltage over the entire route, while the frequency of service being perhaps one-half hour between trains is not sufficient to warrant the very great feeder copper investment that may be demanded by 500-volt direct-current distribution from a single generating station.

The necessity of re-enforcing the trolley voltage at intervals along an extended route has led to the development and adoption of the alternating-current system of distribution, which will be discussed under the general head of:

ALTERNATING-CURRENT SYSTEM OF DISTRIBUTION

The alternating system consists in brief of a generating station containing alternators generating polyphase current of several thousand volts, or generating currents of low voltage, which are stepped up to the required line potential, and transmitting this energy over a high-tension transmission line to sub-stations suitably located. These sub-stations contain step-down transformers and rotary converters, but may contain motor generator sets with an alternating motor wound for receiving the high-tension voltage direct without any intermediate transforming devices.

The system, therefore, possesses the advantages of being able to transmit energy over large areas at high voltage with a consequent small copper investment and small loss, while it can be transformed to direct current of 500 or 600 volts where most needed.

Owing to the large area which it is possible to feed from a single station, any local fluctuations of load are smoothed out and the generating station load curve can be made comparatively free from momentary fluctuations, thus resulting in high coal economy.

Where the length of the transmission line is comparatively small and potentials of not more than 10,000 or 12,000 volts are required for economical distribution, it is possible to wind the alternating current generators for the line voltage, thus dispensing with step-up transformers, but these become necessary where transmission potentials of 20,000 volts or more are necessary to keep line losses small with a reasonable investment in transmission copper, as it is expensive to wind generators for such high potentials. Step-down transformers must always be used in sub-stations where rotary converters are employed, as the voltage of the alternating side of the rotary converter bears a fixed ratio of about 64 per cent of the direct-current voltage, being thus approximately 350 volts for a 550-volt direct-current converter of the three-phase type. Motor generator sets may, however, receive line voltages up to 10,000 volts, but the saving of step-down transformers in this case is offset by the extra cost of the motor generator set over the rotary converter.

The alternating system has to contend with the loss incurred by transforming high-tension alternating current to 500 volts direct current, this loss being approximately 8 per cent at full load of converters and transformers. There is added to this a transmission line drop of 4 per cent or 5 per cent making the total drop from alternating-current generators to the direct-current bus-bars of the sub-station probably 12½ per cent at full load. In figuring upon the adoption of alternating current apparatus for railway work this loss of 12½ per cent must be taken into consideration and balanced against extra interest charges of copper investment and larger direct-current feeder drops of the straight direct-current system. To be more exact, the cost of the energy lost in feeder copper and transforming devices should be added to the cost of the sub-station attendance and interest charges on feeder copper for the alternating system, and compared directly with the cost of power lost in feeders and track, and interest on copper investment of the straight direct-current system.

The cost of maintaining a rotary-converter sub-station becomes a comparatively small factor in the operating expenses, due to the fact that a large part of this expense can be charged up to other accounts. In suburban roads the sub-station attendant combines with his other duties that of ticket seller, train despatcher, etc., duties which would demand the service of a man if a sub-station were not located at that point. In large city systems, where sub-stations are of considerable size, a certain amount of attendance is required, but this expense is small, as the duties of a sub-station attendant are very light.

The alternating system possesses the great advantage of being perfectly flexible and adapted for future growth or extension of the system. The possibility of locating sub-stations in newly opened districts and operating them from the main station with a small line loss and small copper investment, gives the alternating system a distinct lead over the straight 500-volt direct-current system with its limited sphere of action.

In a large city system it is possible to inter-connect the 500-volt feeder network so that during light night loads the outlying sub-stations can be shut down and the entire load thrown upon one or more centrally located stations, thus operating some of the sub-stations with perhaps one shift of attendants.

Modern suburban cars operating at speeds between 40 miles and 50 miles per hour, consume nearly 100-kw average for a 25-ton car, but demand two or three times this amount while starting or on severe grades. A direct-current generating station, supplying nothing but a suburban system operating upon half-hour headway, must sustain very violent fluctuations in load, resulting in a coal consumption in the vicinity of 6 lbs. per kw-hour, when the same engines would probably run on 3½ lbs. with a uniform load curve. The alternating current system, by combining the load of several isolated generating stations upon one set of engines, smooths out these violent fluctuations, thereby producing a load curve upon which engines and boilers will operate economically.

There are certain railway projects calling for intermittent running of very large units, demanding a large local consumption of power over an extended line. Trains may not follow each other at sufficiently frequent intervals to warrant the operation of rotary-converter sub-stations located at short distances apart, much less the installation of several isolated direct-current generating stations. Cheap water-power privileges may be in the vicinity of the line, offering an excellent reason for electrically equipping the system, provided the first cost of installation and labor expenses of operating can be kept reasonably low.

The alternating-current induction motor has been in commercial operation for several years, and is being manufactured in sizes of several hundred horse-power, starting with full-load torque or greater when used for such work as hoists, etc. The principles of its construction are well understood, and it can be accurately designed for the work it has to do. A train propelled by induction motors presents some characteristics which are novel from a direct-current motor standpoint.

The speed of the train is fixed not by the voltage of the trolley, as in the direct-current system, but by the frequency of the source of supply, which offers a much surer guarantee of maintaining a fixed schedule speed than the variable voltage supply of the direct-current system. The induction motor also has no commutator, and offers certain advantages in the way of a better dissipation of losses than the direct-current motor, so that its adoption upon long trunk lines presents many advantages.

The main benefit secured by using induction motors on long lines having infrequent travel is the low cost of installation and of operation due to the use of one or more generating stations feeding step-down transformers located along the line which do not require more than casual inspection. The main transmission line may operate at 10,000 volts or 20,000 volts or higher, depending upon the bulk of power and the distance to which it is to be transmitted, while the trolley or third-rail voltage being no longer confined by the limitations of the direct-current commutator can be raised to several thousand volts if necessary, and, in fact, is only limited by the quality of line insulation. By raising the trolley voltage to several thousand volts it will not be necessary to install expensive third-rail construction, as the currents carried will be small, and can be taken from overhead construction.

The location of step-down transformers along the line is determined by their relative cost and the cost of trolley and feeder copper between them. As they are used for intermittent service only while a train is passing, the step-down transformers can be made of small thermal capacity, but of large momentary overload capacity, so that their cost being small they can be placed comparatively close together, keeping line drops low and raising the efficiency of transmission.

The alternating-current induction motor system thus offers a system where schedule speed can be maintained without respect to line drop or grades, which feature particularly recommends it for the equipment of suburban and trunk lines having no city connections where it will be necessary to operate cars over city streets.

The alternating system requires polyphase motors to insure good starting torque, and to prevent loading up the lines with lagging or useless currents, and three wires being required it is undesirable to operate with a double trolley through crowded city streets. Suburban cars which pick up their passengers through the city have the advantage of providing a continuous passage from the heart of the city to the terminus of the road, while the induction motor suburban road would require a transfer station at the outskirts of the city.

The induction-motor system, therefore, appears best adapted for the operation of long suburban roads having no city connections, and especially those roads where heavy trains operate at infrequent intervals. By emphasizing this latter kind of road it is not intended to convey the impression that the induction-motor system is not equally well adapted for frequent service, but short headway is warranted only in crowded districts where the operation of rotary converter sub-stations would perhaps offer advantages in the distribution of 500-volt direct-current power for local railways.

RECAPITULATION

In the foregoing discussion the attempt has been made to bring out the fact that the electric railway field has become so broad and includes so many different problems in railway engineering that no one system of distribution is adapted for all classes of service. A small congested system, having its lines within easy reach of the power house, which enjoys good coal and water facilities is distinctly a 500-volt direct-current system, or if it has suburban lines where the service is intermittently severe the station should include a series-wound booster in its equipment.

Larger systems, either city or suburban, where the power generated is large and must be transmitted over considerable areas, present the dividing line between the 500-volt direct-current system and the alternating-current sub-station system of distribution. Local details enter into the problem in so large a degree in the consideration of such roads it is only possible to make the general statement that that system of distribution is the better in which operating expenses added to interest on copper investment and fixed charges figure out the lowest.

Suburban roads operating considerable lengths of track over which run heavy cars of 25 tons or 30 tons at speeds of 40 miles and 50 miles per hour can usually find in the alternating system a cheaper method of operation and a considerably cheaper first investment than will be the case if a number of comparatively small isolated direct-current stations were installed, or the attempt made to feed from a single direct-current generating station. The use of

boosters in such direct-current stations for permanent operation must prove expensive, and their operation will contrast unsatisfactorily with the service secured from rotary-converter substations fed from a single generating station well located.

The next class of service into which electricity has been entering in the last two or three years, the equipment of existing steam lines for suburban work and finally for trunk lines, calls for requirements which the alternating rotary-converter system cannot fulfil in many cases, owing to the infrequency of the trains. It may not be advisable in such roads to spilt up the large heavy trains into a number of smaller, more frequent units, especially if these large trains carry freight, owing to the increase in the labor expense account.

The alternating induction-motor system can operate heavy trains as a whole without increasing the large labor account by substation attendance, and can further guarantee the maintenance of a fixed speed over an extended line independent of line voltage and grades, and irrespective of the number of trains moved, a feature which is the basis of the operation of such long-distance roads. Where the service is more frequent, the dividing line between the induction-motor system and the rotary-converter system becomes less sharp, and local considerations may enter as the deciding factor in the adoption of one system or the other.

The system of distribution, like the railway motor itself, must be adapted for the work in hand, and, although the field of the three main systems overlap each other, there are certain fundamental characteristics of each which particularly adapt them for the operation of their own specific class of service.

Mr. Davis' Paper

Boston, Mass., Sept. 18, 1900.

Editors Street Railway Journal:

Dear Sirs.—I beg to call your attention to a typographical error in the paper which I read before the New England Street Railway Club on Sept. 15. Near the end of the paper I am made to say: "The fluctuation in watts, or energy, demand on the dynamo does not increase in proportion to the drops." What I did say was: "The demand on the dynamo does not increase in proportion to the amperes, because at the moment of the pull the generator voltage drops."

I also note that in the discussion Mr. Spring is quoted as saying: "The presence of the battery enables him to start the rotaries from the alternating current end." What he did say was: "The battery enables him to dispense with starting the rotaries from the alternating current end."

Philip W. Davis.

Train to the Kansas City Convention

The committee on transportation to the Kansas City Convention has issued the following circular:

CIRCULAR

The committee beg to advise that they have arranged with the Boston & Albany and New York Central & Hudson River Railroads for the accommodation of delegates and others, attending the above convention, as follows:

Leave Boston,	B. & A.	10.45 A. M.	Sunday, Oct. 14th.
" Worcester,	"	11.47 A. M.	" " "
" Springfield,	"	1.08 P. M.	" " "
Arrive Albany,	"	4.10 P. M.	" " "
Leave New York,	N. Y. C.	1.00 P. M.	" " "
" Poughkeepsie,	"	2.43 P. M.	" " "
Arrive Albany,	"	4.15 P. M.	" " "
Leave Albany,	N. Y. C.	4.30 P. M.	" " "
" Utica,	"	6.48 P. M.	" " "
" Syracuse,	"	8.15 P. M.	" " "
" Rochester,	"	10.05 P. M.	" " "
Arrive Buffalo,	"	11.55 P. M. (E. T.)	" "
Leave Buffalo,	L. S. M. S.	11.00 P. M. (C. T.)	" "
" Cleveland,	Big Four	3.35 P. M.	Monday, Oct. 15th.
" Indianapolis,	"	11.45 A. M.	" " "
Arrive St. Louis,	"	6.45 P. M.	" " "
Leave St. Louis,	Wabash,	10.15 P. M.	" " "
Arrive Kansas City,	"	7.00 A. M.	Tuesday, Oct. 16th.

The train will consist of Pullman vestibuled drawing room sleeping cars, and dining car, serving meals through to Kansas City. A special representative of the New York Central will accompany the party to Kansas City.

RATES OF FARE

Special rate of one and one-third fare on the certificate plan has been made, and delegates, when purchasing tickets, should ask ticket agent for certificate, which, on presentation at Kansas City, will secure one-third fare for the return trip. Sleeping cars at regular rates.

The committee in charge would respectfully urge that all who take the special train at New York, or stations on the New York Central & Hudson River Railroad Company, to communicate with Milton C. Roach, general Eastern passenger agent, New York Central & Hudson River Railroad, 1216 Broadway, New York, stating exact accommodations required, and from what point.

Fare from New York, one way, $31.75. Sleeper, one way, $7.50. Money can be remitted to Mr. Roach direct.

Those who will take the train at Boston and stations on the Boston & Albany Railroad should communicate with J. L. White, passenger agent, Boston & Albany Railroad, 366 Washington Street, Boston.

Reservations will be made in order as received, and prompt notification of assignment made to applicant.

The committee would respectfully suggest that delegates and their friends should make early arrangements. Applicants should address or call on ticket agent, Wabash Railroad, at Kansas City, for the return trip.

If the number will warrant, arrangements will be made for a special train from New York, Sunday morning about 10 o'clock, arriving at Kansas City Monday evening. The committee therefore earnestly requests all those who intend going to notify its members at once, so that, if possible, the necessary plans for the special may be made.

H. H. Vreeland, Chairman.
James H. McGraw,
T. C. Martin,
Charles W. Price,
Committee for New York.

Charles S. Clark,
Committee for Boston, 8 Oliver Street, Boston.

Street Railway Patents

[This department is conducted by W. A. Rosenbaum, patent attorney, 177 Times Building, New York.]

STREET RAILWAY PATENTS ISSUED SEPT. 10, 1900.

657,622. Ice-Removing Mechanism for Railroads; J. J. Shirkey, Chicago, Ill. App. filed April 30, 1900. A series of spring supported wheels adapted to crush, grind and brush aside ice and sleet on third rails.

657,668. Automatic Railroad Frog; C. W. McKinney, Butte, Mont. App. filed July 5, 1900. Details of construction.

657,669. Air-Brake; J. J. Nef, New York, N. Y. App. filed June 22, 1898. Comprises automatic pump governing and controlling devices and friction clutch controlled by pump governer to throw the pump into and out of operation.

657,690. Switch Operating Apparatus; M. W. Brown, E. A. Byrne and J. Gilsenan, Newark, N. J. App. filed May 24, 1900. A box located between the rails underground contains a pivoted lever which is adapted to throw the switch tongue in either direction. A pair of links extend from this lever and connect with plates located at the surface of the ground. Pressing upon either of these plates to throw the switch may be exerted from a passing car through suitable levers carried by the car.

657,746. Body Bolsters for Railway Cars; E. W. Palmquist, St. Louis, Mo. App. filed June 4, 1900. A cast body bolster consisting of sides having horizontally extending flanges, a bottom provided with center and side bearings, and webs that tie the sides together at the top.

657,751. Rail-Joint; W. J. Whitaker and S. M. Gruber, Dravosberg, Pa. App. filed June 26, 1900. The rails are provided with extending tread portions so that when the ends of the rail abut a recess will be formed beneath the tread. A block of a contour similar to the web and base of rail is fitted in the recess, and the joint then mounted between fish-plates, which are formed integrally with the chair for supporting the base.

657,811. Rail-Joint; T. C. Clarke, New York, N. Y. App. filed Feb. 21, 1900. Comprises a pair of base plates upon which the rails rest, each plate having clamping lips for engaging the flanges of the rail and a girder formed by bending the outer portions of the plate downwardly, so that a transverse bolt may pass through such bent portions and secure the two plates. The bolt lies beneath the rail.

657,870. Railway Rail and Joint; S. Hazard, Cincinnati, Ohio. App. filed July 27, 1899. A railway rail of the T type, having an eccentric head reduced in depth upon one side and its flanges bearing proportionately projected upon the opposite or gage side of the head.

657,888. Joint for Railway Rails; J. F. Scullen, Chicago, Ill. App. filed Feb. 26, 1900. The abutting ends of the rails are beveled, forming an obtuse angled opening into which a correspondingly shaped section rail is fitted; the latter bridging the joint and being bolted to both.

PERSONAL MENTION

MR. J. S. SYMINGTON, president of the Sarina Street Railway Company, of Sarina, Ont., died suddenly a few days ago.

MR. A. N. CONNETT, of the J. G. White Company, Ltd., of London, and recently chief engineer of the French Thomson-Houston Company, of Paris, has been awarded a gold medal by the authorities of the Paris Exposition for the best exhibit on trolley construction.

MR. J. R. WHARTON, manager of the Butte Consolidated Railway Company, of Butte, Mont., was recently tendered a banquet by his employees as a tribute of esteem and a mark of respect. The banquet hall was gorgeously decorated for the occasion, and covers were laid for thirty-six guests. A most excellent repast was enjoyed, after which Mr. Wharton was presented with a gold watch, chain and charm by his employees.

MR. A. L. PARKER has recently been appointed second vice-president of the Detroit, Rochester, Romeo & Lake Orion Railway Company, of Detroit, Mich. Mr. Parker was formerly general secretary of the Y. M. C. A. at Detroit, and a year ago associated himself with John Winter, Oliver H. Law and Frank C. Andrews in their electric railway enterprises. They are the promoters of the Detroit, Rochester, Romeo & Lake Orion Railway, and the appointment is made in recognition of the valuable service rendered by Mr. Parker in the projection of different lines in which they are interested.

ENGINEERING SOCIETIES

AMERICAN SOCIETY OF CIVIL ENGINEERS.—At a regular meeting of this society, held Sept. 19, L. C. Montony presented a paper entitled "The Ninety-Sixth Street Power Station of the Metropolitan Street Railway Company, of New York City."

NEWS NOTES

[*News notes for this department are solicited.*]

SAN FRANCISCO, CAL.—The Market Street Railway Athletic Club and Band gave an entertainment and dance at their new hall and clubroom at Valencia and Twenty-Eighth Streets on Aug. 31. An interesting prrogramme of musical and athletic events was presented.

NEW HAVEN, CONN.—The Winchester Avenue Railroad Company is considering the equipment of its closed cars with vestibules.

DENVER, COL.—It is stated that J. Brisben Walker, of Irvington, N. Y., has become interested in the Denver, Boulder & Northern Railway, and that the construction of the line is now assured.

WASHINGTON, D. C.—It is said that the officials of the Washington Traction & Electric Company are considering a plan for hauling farm products from the adjacent country. Large quantities of milk and vegetables can be brought into the city, and it is thought that this would prove quite profitable.

WASHINGTON, D. C.—The officers and employees of the Washington Traction & Electric Company are planning to form a relief association for the benefit of the 950 men employed by the company. President F. C. Stevens has promised to give $1,000 for the company as a nucleus for the fund. The monthly dues will be 50 cents or $1, and there will be an assessment of 10 cents on the death of any member. It is said that the establishment of a loan branch is contemplated.

CHICAGO, ILL.—A misplaced switch caused a car of the Calumet Electric Street Railway Company to jump the track at Stony Island Avenue and Seventy-Ninth Street a few days ago. The car ran into a ditch. Five passengers were badly shaken up, but were uninjured.

EAST ST. LOUIS, ILL.—Mayor Mathews, of Collinsville, has vetoed the ordinance granting the Mississippi Valley Railroad Company an extension of time for the completion of its line. The company applied for a charter a couple of years ago, and offered to build a line from the northern limits of East St. Louis along the Collinsville Road to the city of Collinsville, on the bluffs. Later the company applied for and was granted an extension in the matter of time for the completion of the line. The two years' extension was up a couple of months ago, and the company took another extension to Jan. 1, 1901. It was understood that the line could not be built by that time, and the company, by petition, applied for an extension of time at a recent meeting of the Council. The request was allowed after a fight in Council, but Mayor Mathews claims that the company has not kept its promise, and that he does not propose to let the road occupy the streets under the present ordinance, or even an extension of it.

CHICAGO, ILL.—The traffic report of the South Side Elevated Railroad Company for August shows that 1,908,267 persons were transported, as against 1,630,569 for August of 1899. The daily average for August, 1900, was 61,557, as against 52,599 for August, 1899. Below are given the traffic records so far this year, with comparison with those of last year:

	1899	1900
January	1,821,609	2,154,624
February	1,688,176	1,961,400
March	1,981,179	2,240,184
April	1,916,340	2,149,960
May	1,847,228	2,117,176
June	1,683,510	2,036,760
July	1,631,964	1,890,132
August	1,630,569	1,908,627

CHICAGO, ILL.—The traffic report of the Metropolitan Elevated Railroad Company shows that 2,432,167 passengers were transported in August, 1900, as against 2,110,170 for August, 1899. This year's traffic figures compare with those of last year as follows:

	1899	1900
January	2,242,490	2,756,135
February	2,109,632	2,593,304
March	2,456,533	2,929,748
April	2,323,920	2,712,900
May	2,352,590	2,674,928
June	2,172,990	2,466,180
July	2,093,338	2,287,490
August	2,110,170	2,432,167

BILOXI, LA.—Albert L. Covel, chief engineer and general manager of the Gulf Coast Electric Railway, is hopeful of beginning work on the new line in the near future. The road is to extend from Biloxi to Gulfport, with a branch to Handsboro.

DETROIT, MICH.—The People's Street Railway Company, a new line, is about to make application to the Council for a street railway franchise. Messrs. Stevenson, Merriam, Eldredge & Butzel are counsel for the company.

DETROIT, MICH.—There is talk of building a third electric railway from Detroit to Pontiac. Thomas W. Palmer is said to be behind the latest project.

DETROIT, MICH.—The Detroit, Rochester, Romeo & Lake Orion Railway Company has recently issued a beautiful brochure entitled "Scenics," descriptive of its line. It is printed on wood-cut paper, the reading being in red and the illustrations in green ink. The illustrations represent scenes along the line, and, from an artistic point, it is a fine specimen.

ST. LOUIS, MO.—The attorneys for the St. Louis Transit Company have filed a motion in the Supreme Court to quash the writ filed by the Attorney-General of the State to annul the transit franchise.

ST. LOUIS, MO.—The Suburban Railroad Company has applied to the Florissant Town Council for a franchise to extend its lines to the corner of St. Francis and Castelloe Avenues.

CAMDEN, N. J.—An ordinance granting the Camden & Suburban Railway Company a franchise for the construction of an electric railway through Riverton has been passed by the Riverton Council.

JERSEY CITY, N. J.—The North Jersey Street Railway Company will shortly make application to the Council of East Orange for a franchise for the construction of electric railway lines on Central and Springdale Avenues.

JERSEY CITY, N. J.—The North Jersey Street Railway Company and the Jersey City, Hoboken & Paterson Street Railway Company have completed arrangements with the postal authorities for transporting the mails between Jersey City, Hoboken, Bayonne and Union Hill.

CAMDEN, N. J.—The South Jersey Gas, Light & Traction Company, which recently completed a consolidation of Southern New Jersey gas, light and street railway companies, has elected officers as follows: Anthony R. Kuser, of Newark, president; William J. Bradley, of Camden, vice-president; Thomas N. McCarter, Jr., of Newark, treasurer. Directors: Uzal H. McCarter, Forrest F. Dryden, Chandler W. Riker, of Newark; Thomas A. Nevins, of East Orange; John L. Kuser, of Bordentown; William J. Thompson, of Gloucester; John J. Burleigh, of Camden; Herbert W. Johnson, of Merchantville; Charles Watson, of Camden; Barker Gummere, of Trenton; Frank Bergen, of Elizabeth; Thomas C. Barr, of Orange; Frank W. Montgomery and Maitland F. Griggs, of New York. The authorized capital stock of the company is $6,000,000, of which $3,389,000 has been issued. The company has authorized a mortgage in favor of the Fidelity Trust Company, of Newark, to secure an issue of $6,000,000 5 per cent gold bonds. Of this issue, however, only $3,160,000 are to be issued at present. The remainder will be held in the treasury for future needs. Among the companies included in the consolidation are: Camden Gas Light Company, Camden Gas & Fuel Company, Camden & Burlington Gas & Electric Company, Consumers' Gas Company, of Woodbury, East Side Gas Company, Gloucester Electric Company and the Camden, Gloucester & Woodbury Electric Railway Company.

PLAINFIELD, N. J.—A car of the Elizabeth & Westfield Street Railway jumped the track at the curve at the corner of Summit and South Avenues, a few days ago, and plunged 50 ft. across the street into a tree standing in the Central Railroad Station Park. The impact nearly split the car in two, and it was wrecked so that it will be impossible to repair it. The motorman, conductor and several passengers were injured.

AMSTERDAM, N. Y.—The Amsterdam & Hagaman Traction Company has made application to the Railroad Commissioners to construct its proposed electric line from Amsterdam to Rockton and Hagaman.

BUFFALO, N. Y.—The Buffalo, Niagara Falls & Rochester Railway Company has made application to the Town Board of Tonawanda for permission to construct and operate a street railway through the town.

BROOKLYN, N. Y.—A resolution to compel the Brooklyn Rapid Transit Company to put its trolley wires under ground was introduced at a meeting of the Board of Aldermen held Sept. 18. It was referred to the committee on railways.

BROOKLYN, N. Y.—Electric motor cars were run on the Lexington Avenue elevated line of the Brooklyn Rapid Transit during the rush hours for the first time on Sept. 5. The work of equipping the Broadway and Myrtle Avenue lines is progressing rapidly.

NEW YORK, N. Y.—The Manhattan Elevated Railway Company's escalator, now being put in by the Otis Company at Twenty-Third Street and Sixth Avenue, is unlike the moving incline plane at Fifty-Ninth Street and Third Avenue. This escalator is a moving stairway, or series of steps passing upward. A passenger may stand still on a step and be carried up, or if he desires to he may beat the stairs by walking constantly upward, as on an ordinary stairway.

NEW YORK, N. Y.—The Metropolitan Street Railway Company is now reconstructing its Park Row tracks opposite the Postoffice, so as to provide additional terminal facilities for the Fourth & Madison Avenue line, the Second Avenue line, and for a new branch of the Sixth & Amsterdam Avenue and the Eighth Avenue lines. The cars of the Sixth & Amsterdam and of the Eighth Avenue lines, which now have their terminal at Canal Street and Broadway, are to run through Canal Street to Centre, thence south to the Brooklyn Bridge and the Postoffice. The Metropolitan tracks and the Third Avenue tracks are to be connected with the Broadway line in front of the Postoffice.

LIMA, OHIO.—The employees of the Lima Railway Company are on strike.

AKRON, OHIO.—The Northern Ohio Traction Company has removed its general offices to a fine suite in the new Hamilton Building.

MANSFIELD, OHIO.—The Mansfield Railway Company has commenced work on a new car house on East Fourth Street.

CLEVELAND, OHIO.—The Northern Ohio Traction Company has made application to the Cuyahoga County Commissioners for permission to double track its road within the county limits. The entire road is to be double tracked.

MANSFIELD, OHIO.—It is stated that negotiations are under way for the sale of the franchise secured by T. Y. McCrary for an electric railway between Mansfield, Savannah and Wellington, to W. L. Elkins, of Philadelphia. Report has it that the terms will be $50,000 in cash and a block of stock in the road.

SPRINGFIELD, OHIO.—At the annual meeting of the stockholders of the Springfield Railway Company, held here a few days ago, officers were elected as follows: Oscar T. Martin, president; H. J. Crowley, vice-president; C. L. S. Tingley, secretary and treasurer; Oscar T. Martin, H. J. Crowley, C. L. S. Tingley, S. G. De Coursey, W. H. Shelmerdine, Silas W. Pettit, Theodore Troupe and John H. Miller, directors. A number of improvements will be made in the road, and Lansdowne Park will be opened up as a summer resort next spring.

TOLEDO, OHIO.—A misunderstanding of the new traffic arrangement between the Toledo, Bowling Green & Fremont Railway Company and the Maumee Valley Electric Railway Company, whereby the cars of the former are taken charge of at Perrysburg by employees of the latter and operated over a new belt line into the city, resulted in a collision between two Bowling Green cars on the first day the new arrangement went into effect. A dozen people were injured.

TOLEDO, OHIO.—The Toledo, Fremont & Norwalk Electric Railway carried over 5000 passengers Sunday, Sept. 9, which was the official opening of the road. The line will be in operation as far as Bellevue within two weeks, and to Norwalk by Nov. 15. Twenty-two cars are now in operation, and it is stated that a number of baggage-express cars are to be ordered in the near future.

COLUMBUS, OHIO.—The Columbus Railway Company has made application for a new twenty-five-year blanket franchise covering all the streets in the city now operated upon by the Columbus Railway Company, together with a franchise on South Parsons Avenue and on West Goodale Street. The ordinance provides that the city shall receive $7,500 annually and a percentage on the gross earnings to be agreed upon later. Besides the extensions desired, the ordinance provides for the connection of the company's lines at several points on High Street and grants the same fares now in vogue, with transfers on all cash fares of 5 cents. A section provides that as rapidly as the requirements of the plant and the service demand during the life of the grant, it shall expend not less than $750,000 in extensions, equipments and betterments. Another section provides that the company shall keep on deposit with the city at all times the sum of $1,000 as an emergency fund, against which the city may draw for the cost and expense of any repairs made by the city which, by the terms of the ordinance, should have been made by the company and which the company has neglected to do.

COLUMBUS, OHIO.—The Columbus, London & Springfield Electric Railway Company is making arrangements for the lease of a building to be used as a temporary power house. A permanent building will be erected at London. The three-phase system of distribution will be used, and a single power house will furnish current for the entire road.

HAMILTON, OHIO.—The annual meeting of the stockholders of the Southern Ohio Traction Company was held here last week. Directors were elected as follows: M. J. Mandelbaum, Jacob Mandelbaum, Will Christy, James D. Christy, A. E. Aikins, D. H. Kimberly, E. G. Tillottson, J. R. Nutt, Peter Schwab, G. A. Rentschler, F. T. Pomeroy and J. Lemprecht. Officers: Will Christy, president; M. J. Mandelbaum, first vice-president; Peter Schwab, second vice-president; F. Pomeroy, secretary and treasurer; Will Christy and M. J. Mandelbaum, executive committee. Reports of the treasurer showed the road to be in very prosperous condition. The question of improved service between Dayton and College Hill was decided upon, and will be adopted at once. The running time between the two towns will be reduced to three hours. The construction of new lines was discussed at the meeting.

READING, PA.—At the annual meeting of the Pottstown, Bayerstown & Reading Railway Company the following officers were elected: E. C. Watson, president; B. J. Woodward, vice-president; James M. Crawford, secretary; directors, E. E. Watson, B. J. Woodward, J. M. Crawford, of Philadelphia; M. G. Taylor, F. P. Esterly, of Reading. The company has a charter to construct an electric railway from Reading to Bayerstown, 18 miles, and thence to Pottstown, 8 miles.

BEAVER, PA.—At a special meeting of the directors of the Beaver Valley Traction Company held a few days ago, most of the members of the old board tendered their resignation and their positions were filled by the Philadelphia capitalists, who recently purchased the road. New officers have been elected as follows: Frederick Snyder, of Philadelphia, president; Walter Bilyeu, of Philadelphia, treasurer. W. P. McConnell will retain his present position as secretary. At the meeting large measures were taken for the building of the additional lines. The work of constructing the line to Monaco will be begun as soon as franchises are signed.

CLARKSVILLE, TENN.—The coupon ticket system has been adopted by the Clarksville Street Railway Company. The coupon books are used in four forms. One contains six green tickets, which sell for 25 cents; another, containing twenty-four white tickets, sells for $1, each ticket good for one fare; another, containing twenty red tickets, sells for 50 cents, each ticket good for one fare for children twelve years of age or under, and another containing yellow tickets, which is issued to those who have passes. In this way a complete record can be kept of the exact number of passengers hauled each day. The company will allow a discount of 5 per cent on all sales amounting to $5, and 10 per cent discount on sales amounting to $10 or more.

SALT LAKE CITY, UTAH.—The construction of the proposed Salt Lake Valley Electric Railroad between Salt Lake and Ogden has been abandoned, for the present at least. The company was not prepared to begin work when the franchise stipulated, and the franchise has lapsed.

NORFOLK, VA.—There is talk here of passing a law to compel the street railway companies operating here to carry school children for 3 cents.

WHEELING, W. VA.—The Northern Ohio Electric Company, which is to build an electric railway from Wheeling to Wellsburg, has organized permanently. Howard Hazeltt has been elected president; John G. Welty, vice-president, and John Arbenz, secretary and treasurer. The company has already secured the right of way and has ample financial backing. The road will be 15 miles in length and will traverse a fine agricultural country.

MILWAUKEE, WIS.—The Council has passed, over the Mayor's veto, resolution to enter into a five-year contract with the Milwaukee Electric Railway & Light Company.

MILWAUKEE, WIS.—The Milwaukee Electric Railway & Light Company has had a street sprinkler built at its Kinnickinnic Avenue shops. The sprinkler will be used experimentally on the National Avenue line. It was built for special occasions only.

TWO RIVERS, WIS.—The petition presented by T. Higgins, of Neenah, for a franchise here calls for a fifty-year grant and right of way over some of the principal streets here, traversing the entire city. The promoters agree to have the line in operation within two years.

MILWAUKEE, WIS.—The Milwaukee Electric Railway & Light Company is now receiving bids for an addition to the boiler room of the River Street power house of the company, a distance of 140 ft. along the river front. The addition will be uniform with the new power house and will make the frontage 240 ft. on the river. The new boiler house will occupy about one-third of the depth between River Street and the river. It is estimated that the building will cost $100,000. The old boiler house will be torn down and work commenced upon the new one just as soon as the contract for the new one has been awarded.

MANITOWOC, WIS.—The City Council is being flooded with petitions for street car franchises. Those asking the new franchises are all local men except two, and are Judge Craite, John Murphy, Henry Schmidt, Thos. Torrison, W. H. Walker, of Milwaukee, and J. M. Seamann, of Sheboygan. They want a thirty-five-year franchise and promise to construct an interurban line to Two Rivers. The terms of this franchise are very similar to those now before the Council. A committe has been appointed to examine both.

CANADIAN NOTE

NIAGARA FALLS, ONT.—The Niagara, St. Catherines & Toronto Electric Railway Company has been granted permission to cross the upper arch bridge into this city. It is now possible for a person to take a car in Buffalo and with one or more transfers ride direct to Toronto.

STREET RAILWAY JOURNAL

WEEKLY NEWS ISSUE

SATURDAY, SEPTEMBER 29 1900.

THE CONVENTION OF THE NEW YORK STATE STREET RAILWAY ASSOCIATION

The convention of the New York State Street Railway Association, held in Buffalo, Sept. 18 and 19, was the most successful convention in the history of the association. This is saying a great deal, for the association has always been a vigorous one, and particularly during the last four or five years, under the presidency of G. Tracy Rogers, has enjoyed a most healthy growth. This has been shown not only by the increased attendance at the conventions and the greater value and interest of the papers presented at the meetings, but also by the increased support given to it by street railway companies in the State, and by the important and influential work which it has carried on for the benefit of the industry in general. The re-election of President Rogers and Secretary Robinson was a well-deserved recognition of the faithful services of these officials, while the executive committee, consisting of Messrs. Vreeland, Ely, Nicholl and Rossiter, have been untiring in their efforts to promote the best interests of the association, and through it all the street railways of the State. The future outlook for the association is most bright and promising. The street railways of the whole State, both large and small, are working harmoniously for the common end, *i. e.*, to make the association a power in the State, that it may be the greatest possible benefit to the individual members.

* * * *

We have often had occasion to commend the organization and the work of the New York State Association many times, and have expressed the hope that railway men in other States would give their State associations the support accorded to that in New York State. While it is undoubtedly true that many of the State associations are doing good work and have the hearty co-operation of the street railway managers of the States in which they exist, it is undeniable that it is not true of all of them, while many States have no associations at all. That many benefits are to be derived from co-operation and united action is indisputable, and as the street railway companies are largely under the supervision of State authorities, membership in State bodies furnishes the means by which the companies can best unite to present their claims and to secure the benefit which organized action is sure to bring.

* * * *

Some of the State associations are organized and conducted purely for executive action, others largely for social purposes. The New York State Association has, wisely we think, always made the discussion of technical questions involved in street railway operation the important feature of its annual gatherings. This has attracted the attention of the operating officials and managers of the smaller roads, whose time is devoted principally to questions of operation. The papers have usually been of high merit; this year extremely so, and, being limited in length, between ten and a dozen subjects are usually brought to the attention of the delegates for discussion. The advantages of a convention of this kind are shown by the fact that the attendance at Buffalo last week was not limited to railway managers in New York State, but, although purely a State convention, companies of other States were represented and participated in the debates. Under these circumstances, it may seem somewhat ungracious to criticize in any respect the meetings of the association. We still believe, however, that the value of a convention of this kind lies chiefly in the discussion which follows the readings of the papers, as this discussion not only brings out the opinions of the different delegates on the subjects treated, but even elicits additional points from the person reading the paper. We hardly think that this point will be questioned, so that any method by which the discussions can be encouraged is worthy of serious consideration. We believe that this can best be accomplished by following the practice of most scientific bodies in conventions of this kind in having the papers printed and distributed to the members some time before the convention, and appointing leaders who will be prepared in advance to open the discussion on their respective

topics. Under the present plan, while a delegate may be apprised of the subjects of the papers to be read, he can have no idea of the way in which these subjects will be treated or the points to be brought out by the authors of the papers, nor can he always remember all the facts stated in a paper, upon hearing it read once at the convention. If, however, he had the paper before him in type before he went to the convention, he could discuss the subject under consideration to much better purpose than would otherwise be possible. That this is true is proved by the fact that the "special topics for discussion," of which notice had been previously given, brought out much more experience than did the remarks on the papers themselves. Again, if the papers were printed, the time of the association need not be taken up by the reading of them in full. Instead they could be presented by title or abstract, and the entire time at the disposal of the association could be devoted to discussion.

* * * *

Another point of value to the association brought up in the discussion was in regard to attendance, and a reference was made by Mr. Vreeland to the methods employed in regard to the attendance at the meetings of some of the steam railroad associations. In these associations regular delegates are sent from the different companies to the conventions, and the fact as to whether they attend the meetings to which they are delegated is ascertained by a roll-call at the beginning of each session. In this way the presence of each delegate is assured, and if any point requiring the concerted action of the members is brought up, the association as a whole knows that a delegate from each road interested is present, either to give his approval or to name his reasons for dissent. While this arrangement, in one sense, may be more important for steam railroads, which interchange rolling stock and thus need certain standards to a greater extent than do street railways, yet we see advantages in a course of this kind. Whether or not any such regulations will be adopted by the association, the suggestion is certainly worthy of consideration.

* * * *

Taking up now the papers themselves, we find that they divide easily into five classes: First, the relations of the officers of a company to the employees, represented by Mr. Connette's paper; second, the relation of the company to the public, represented by Mr. Uebelacker's paper; third, technical papers, relating to electric railway operation, covered by the papers of Messrs. Mann, Nostrand, Henning, Norris, Nicholl and Armstrong; fourth, the legal department of railway operation, as related to damage suits, covered by Mr. Patterson's paper; and fifth, new motive powers, discussed by Mr. Cooke.

* * * *

Mr. Connette's paper, which was printed in our last issue, was received very favorably by the association, and showed that the principles laid down by him were regarded by those in attendance as sound in every particular. Mr. Connette's position indicates that the most successful managers at present do not regard their employees as machines but as fellow-citizens, and that corporation managers and directors have souls, even if the corporations themselves do not. He believes that this position is not only sound ethically, but profitable in a business way, and that that road is the most successful which insures the co-operation of the employee as well as his service. The discipline should be kind and considerate, and at the same time firm and positive, and there should be no prejudice or favoritism in the management of the men. At the same time merit should be rewarded, where possible.

* * * *

The paper presented at the convention by Mr. Uebelacker treated of the management of a combined system affording electric railway, gas and water service. Consolidations are the order of the day, and our readers are familiar with those which comprise several railway companies or railway and lighting companies. That all the public utilities can be combined under one management is not so familiar an idea, although Mr. Uebelacker believes certain economic advantages can be derived from such an organization. This lies not so much in the reduction of the operating force as in a better utilization of its energies and a co-operation between the different departments.

* * * *

The technical papers presented at the convention were of a high standard. The increased use of the storage battery as a station auxiliary was strikingly shown by three papers, one of which described its use on a small road, while the other two treated of its use on a large system, as in Buffalo. In all cases the authors considered that the benefits derived from its use were considerable. Mr. Armstrong took up the subject of electric railway power transmission, a subject of growing importance with the increase of electric railway mileage and the distance to which the power is transmitted. Mr. Mann discussed the power station, outlined the principal losses and showed where economy is possible. He believes the greatest liability to loss is in the fire room, and too much attention cannot be given to insuring a perfect combustion under the boilers. Mr. Danforth read two instructive papers, one on "Rotary Transformer Stations," the other on "Snow and Snow Plows." The former described the general practice of the International Traction Company, whose work in the utilization of alternating current for railway service has been of the pioneer character, and this paper is of great value to those who employ or are intending to employ alternating current for driving rotary converters. His paper on the snow plow was a careful consideration of this question, and as this company has developed, from its own experience, a number of different plows, his conclusions will be useful to those who have heavy snow falls to contend with. His opinion is, briefly, that under the conditions existing in Buffalo, several different plows are required: a nose or share plow for light and medium work, a rotary for heavy work, and a steel broom sweeper for packed or wet snow. The Rochester & Sodus Bay Railway was described by Mr. Nicholl, of Rochester, whose paper was listened to with much interest. The line is a new one, embodying the latest improvements in interurban work, and is a good example of this popular type of road.

* * * *

The subject of Mr. Patterson's paper was on the best method of handling accidents from the legal standpoint. This is an important subject—much more important than managers often think, until postponed damage suits rise up to confront them and condemn procrastination. Mr. Patterson called attention to a growing evil in the rapid increase of damage suits, and showed that in the case of his own company, claims for damages have increased very rapidly during the last few years, and these entirely out of proportion to the actual injuries sustained. This would seem to call for legislative relief, and some way should be devised for preventing the unreasonable damages too often awarded by oversympathetic jurors.

* * * *

The paper by Mr. Cooke on the "Compressed Air Motor" was the first paper on this subject presented at a street railway convention, and attracted great attention. The managers of the New York system think so well of this power that they are going to great expense to determine its value for railway service, and Mr. Cooke's paper, as defining what has already been accomplished, was a most valuable contribution to the science of street railway operation. The paper received the careful attention of those present.

* * * *

A word should be added in regard to the large attendance of supply men at the convention. This attendance has come to be a feature of all street railway conventions, and properly, too, as the manufacturer is as much interested as the railway manager in making a success of electric railroading. The number of these "outside delegates" at the Buffalo convention was extremely large, and the interest taken by them in the technical proceedings greater than usual, both of which facts were favorably commented upon by the delegates present.

As a whole, the convention was marked with more solid work with less diversion than ever before, and added greatly to the already high prestige enjoyed by the New York State Association.

The Annual Convention of the New York State Street Railway Association

Four of the papers presented at the Buffalo meeting of the New York State Street Railway Association, on Sept. 18-19, were published in the last issue of this paper. The proceedings of the convention follow:

TUESDAY, SEPT. 18

The convention which met at the Iroquois Hotel was called to order by G. Tracy Rogers, of Binghamton, N. Y., president of the association, at 10:45 a. m. After the roll-call the president delivered his annual address. This was published last week. Secretary Robinson then read the report of the executive committee. It is given below:

REPORT OF EXECUTIVE COMMITTEE

MEMBERSHIP

The tendency of the times continues to cause the consolidation of existing railroad properties, and necessarily leads to the withdrawal from active participation of many of the old and valued members who have, for a long time, been associated with us. In spite of this loss, we are happy to have enlisted the support of several new companies, which are about to embark in active construction. Our membership now consists of those companies which represent the bulk of capital invested in the street railway enterprises of the State.

We have pleasure in stating that the Elmira & Seneca Lake Railroad Company, the Black River Traction Company and the Rochester & Sodus Bay Railroad Company have joined our association during the present year.

We regret to find that there is a number of companies which are not members of the association, and urge upon the present members that determined and persistent efforts be made to secure the union of every outstanding road in the State with the association.

LEGISLATION

The State Legislature last year continued to be the producer of a large number of bills. While 245 different bills touching organization, construction, operation and taxation were introduced, but few of them made progress. Only one objectionable bill reached the Governor, and was terminated by his veto. Such a volume of legislation required watchfulness and care on the part of the officers of the association, and careful study by the counsel of the various members.

Many members of the Legislature are entitled to an acknowledgment of the unvarying courtesy and attention shown by them to the street railways in their careful consideration and just disposition of the numerous bills presented to the committee.

The association is to be congratulated on having for its counsel before the Legislature Meyer Nussbaum, of Albany. Mr. Nussbaum's early connection with the Senate has been of great assistance in securing for the association a proper presentation of various legislative measures, while the result attained has been mainly the result of his conscientious and felicitous presentation of the matters in hand.

H. H. VREELAND,
W. CARYL ELY,
T. J. NICHOLL,
C. L. ROSSITER,
G. TRACY ROGERS,
Committee.

A resolution was then passed ratifying the action of the executive committee in postponing the date of holding the convention from Sept. 11-12 to Sept. 18-19.

The treasurer's report was then read:

SUMMARY OF TREASURER'S REPORT

Total receipts during year	$7,050.64
Total expenditures during year	4,948.15
Balance in hand	$2,102.49

Then followed the reading of the paper on "Railway Power Transmission," by J. H. Armstrong. This paper was published in full last week.

Mr. Norris.—How much more current will be required with induction motors than where direct current is used?

Mr. Armstrong.—About 15 per cent as an average; 15 or 20 per cent for railway work. With stationary motors it is possible to get along with from 12 to 14 per cent, but in railway work fully 20 per cent more would be required than in the direct-current system.

The next paper read was on "Accidents on Street Railways, Methods Employed in Handling Same, and Preparation for Trial," by D. W. Patterson. This paper was also published in the last weekly issue.

Mr. Nicholl.—I would like to inquire of the gentleman what method he uses to precede the action of these ambulance lawyers?

Mr. Patterson.—That is a matter of detail for the operating department. The moment an accident occurs it is reported by the crew of the car at the depot. It is then telephoned down to the claim department, and some one is immediately sent to look after it. The witnesses are at once interviewed, and their statements taken. After that, the case goes into the hands of investigators; each report going through two or three departments in that way, so that when the case is brought to suit, we have a fairly good idea of what the accident is about.

Mr. Nicholl.—Do you find that you generally make a better settlement by being promptly on the ground, or by waiting for the parties to show up?

Mr. Patterson.—That is a difficult question to answer. There are some cases which it is always better to settle in the first instance. There may, perhaps, be an injury on the spine, similar to a case that happened in Brooklyn. It could have been settled for perhaps about $100 before the lawyers got hold of it, but by the time they finished with him he was brought into court on a stretcher. A great many cases are settled immediately after the accident.

Mr. Robinson.—Mr. Nicholl, in answer to your inquiry, I would state that so far as the Metropolitan is concerned, we divide these accidents into several classes. Of course, those which arise from collision of cars and defective machinery are settled at once. We have investigators, trusted men, who are given money and sent to the injured parties' houses to make as prompt a settlement as possible. So far as street crossing cases are concerned, we do not look for the injured parties at all. The accidents are so numerous that we feel that after they come down to suit and are about being reached for trial, two years being about the shortest time in New York, settlement in that class of case can then be made as speedily as in the beginning. Of course, there are serious accidents which you cannot settle quickly. They run for periods of three or four months before anything can be done with them, and even then it is quite impossible to bring about a reasonable settlement. It is very difficult to say, when the cases get into the hands of lawyers in New York, what is the best method of handling them as a general proposition. There are a great many lawyers who live on accident business in New York. They know the value of a case; do not wish for a settlement, and do not allow their clients to settle. We prefer, as a matter of protection, to litigate with them. There are a great many lawyers having cases against us who have been victims of the company. We have succeeded in defeating them, and in those cases we can settle with the plaintiffs as if we had seen the plaintiffs before. Sometimes we have as many as sixty cases on the calendar, but they will dwindle down to fifteen or twenty when it comes to the time of trial. As I say, the system we use depends as much upon the lawyer who has it for the plaintiff as it does upon the character of the accident.

Mr. Wason.—When a case gets into the hands of a lawyer, do you always settle with the lawyer, or do you sometimes go direct to the injured party?

Mr. Robinson.—That depends upon the class of lawyer.

Mr. Cooper.—Of course, it is considered unprofessional for one lawyer to settle a case after it gets into the hands of another. But don't you think it is a good rule, where a lawyer gets a claim against a street railway company, and instead of going to the party against whom he has the claim, goes direct to the court house with it, don't you think then that we are justified in settling it outside of the lawyer?

Mr. Robinson.—That is a question of legal ethics which is very difficult for me to answer. I occupy rather a divided position, in being both a director and a lawyer of the Metropolitan Company. I can only say from our own standpoint, that there being so many of these cases we do not feel it an insult for lawyers to bring a lawsuit. As soon as they do, we throw up our hands and tell them that they had better litigate, as age will improve the quality of their claim. (Laughter.) I found the other day that I had about six thousand cases brought by lawyers which had never got beyond the serving of summons and complaint.

Mr. Vreeland.—There are just two points in Mr. Patterson's paper to which I wish to refer. With reference to what has been said later, there is a question I would like to speak upon. One was the number of accidents, which was spoken of in the paper. With our system of handling the accident business in New York City, which was started some seven years ago, and has been changed from time to time, better methods introduced, etc., we determined that it was necessary to investigate everything. We found, a few years ago, when our accident cases were handled by several lawyers representing the several properties that make up the whole system, that all the records in the office of the lawyer were the reports furnished by the motorman and conductor on the accident; and also, that only what might be classed as accidents that resulted in severe injury, were reported. Not long since a manager of one

of our syndicate properties came to New York and asked what our monthly report and yearly record of accidents showed. We told him, and also stated the number of car miles, and the number of miles of street covered. He said, "That is something awful," and he cited their record. When we inquired the character of accidents they investigated, we discovered that it was simply where somebody had a leg off, or an arm off, or a skull fractured. Our system is that if a person falls and gets up and brushes his clothes off, apparently unhurt, it is the duty of the conductor to report it. We hold so rigidly to that rule, that our discipline with motormen and conductors is more strict in that particular than in almost anything else. If an accident report comes to the office indirectly, and not through the men who are handling the cars, we mete out the severest discipline that is administered in any connection. Our sixty accidents, in their final result legally, as indicated by Mr. Robinson, may melt down to ten; but we have the information. We found that the worst cases presented to us were often of this small class which were not considered worthy of investigation, and when it came to a question of suit we had no defense; did not even know on what car it occurred.

With reference to the question of stopping cars, distances, etc., a few years ago we had marked on one section of our track the distances, and then had cars run over this section at the maximum speed attainable. They were then to be stopped by the men, who were not to touch their brakes or grip until warned by a torpedo, at which time they were to stop the car as quickly as possible. The distance was measured, and made a matter of record.

When the Railroad Commissioners of the State of New York made their brake tests on our system, they had the best mechanical appliances for indicating speed, distance, etc. In their tests the car under trial was filled with newspaper men, and the man who had charge of the brake that was being exhibited wanted a speed of 15 miles an hour, in order to show in what distance the car could be stopped, and it was found impossible to run the car 15 miles an hour. We could not get up that speed. I immediately turned to the Railroad Commissioners and all who were in the car and said: "Gentlemen, I would like a record made of that. There never was an accident in New York City where it was not reported that the car was bowling along at 45 or 50 miles an hour. Now, here is an opportunity to show that that is impossible." Of course, you know that our lines are run through congested districts. For instance, on our cable road the cables run 6, 9 and 14 miles an hour. By this speed test we have had put very fully before our men the matter of the distance it takes to stop these cars, even with the most improved braking appliances. There were all kinds represented; track brakes, electric brakes, and a combined track and wheel brake; and the tests were very carefully kept by our men, so that we have a record of the distance actually traversed by these cars under all braking conditions before they could be stopped; and I am free to say myself, that I should have understated rather than overstated the distance in which it was possible to stop one of these cars if it had not been for the record.

Mr. Schoeplin.—I am manager of a small suburban street railway, and we have had a number of accidents. My experience has been that the best thing to do is to get ahead of the ambulance lawyers; keep the case out of the hands of the attorneys, if possible. Our road had been in operation about three weeks when we had two serious cases. I immediately started to keep the cases out of the hands of the attorneys. There were thirty or forty in the case, all the neighbors working for some attorney or friend; but I succeeded in settling the cases without any attorneys for $2,500 each, which I think a very good settlement. We have had a number of accidents in the last two years, and I have found that the best thing to do was to keep them out of the lawyer's hands, and settle them just as quickly as possible. We had one case which it was necessary to fight in the courts, and the witnesses we had, the conductor's witnesses, were chums of the young man who was hurt, and were unreliable. The only record that helped us was the police record. If you can get a police record of the accident, it goes a great way with the jury, and it was in that way we won. The jury brought in a verdict of no cause of action. It caused us three weeks of labor, and cost much money to prepare the case. It would have been cheaper to have settled it. Of course, city street railways who have attorneys they pay by the year, can afford to carry cases along for two or three years, but I think most of us find it more desirable, and I believe the Buffalo Street Railway Company has adopted a system of settling of cases quickly.

Mr. Wason.—On our suburban road it is a question whether we have more accidents on the highways or on the private ways. There are several of the suburban roads which have private rights of ways, and have serious accidents. They are bound to cross streets, and people are bound to walk on the track. Where we are paralleling or running on a highway, the man driving on the highway is continually on the watch for a car, and it would almost seem to me, from our experience in both directions, that there are really less accidents on the tracks by the highway than on the private roads. This, on the face of it, would seem a little peculiar, but I am inclined to think it is a fact. I haven't the figures, but I think that of two roads, one running east and the other west, one on the private right of way all the way, and the other on the highway, our accidents have been, in point of dollars and cents, about the same. We try to settle our claims as soon as the accidents occur, rather then let them go into the hands of lawyers. We cannot afford, as a suburban road, to employ lawyers by the year, as city roads do, and I agree with the gentleman of the suburban road, who spoke just now, that for a suburban road it is best to settle the claim promptly. We have settled a number of our fatal cases considerably cheaper than the gentleman who spoke. On our city roads, of course, it is about the same, in a small way, as Mr. Vreeland outlined as the policy of the road in New York.

Mr. Cole.—Mr. President, I have recently been in a number of cases as an expert, and I have noticed that nine times out of ten the case has been sent to the jury to determine upon the question of speed; where they might possibly have obtained a non-suit if it had not been for the question of speed. If, as soon as the accident occurs, the master mechanic, with the witnesses, took the car out and put a speed indicator on, there would be no question as to the speed of his car. Twice recently I have obtained a non-suit where it has been just the question of speed.

Mr. Hasbrouck.—Corporations have no souls, you know, but it is wise to show a sympathy. Before it grew to such tremendous proportions with us I used to show a good deal of sympathy, and I have settled a case for $1000 sometimes, giving a man $100 in money and $900 in sympathy. (Laughter.) It really worked very well. They often say: "Yes, you soulless corporations never come near us." I received a letter from one of that class of lawyers who always now takes the precaution to serve us with a notice of lien after he serves his summons. He told me that Mrs. Fagin had been injured; that she lived so and so. I immediately went to see Mrs. Fagin myself, and within an hour I settled with her for a small sum. The lawyer was highly indignant when he found that I had been to see Mrs. Fagin and settled with her. I told him that there was a certain courtesy between lawyers, perhaps, but I did not own a cent's worth of courtesy. (Laughter.)

Mr. Harrington.—I am manager of a little road down in Camden, N. J. We average about five or six accidents a day, including everything. We sometimes settle behind the lawyer's back, in the case of lawyers for whom we have not any respect, of which we have a few. We have more accidents on open than on closed cars. We have several cases where employees have been injured and which came up after they had been discharged. We found that our accidents cost us each year about 2½ per cent of our receipts. Last year it was 7 per cent. We think it due to the fact that the public is becoming bolder, and it is a question, in our mind, whether it is expedient to settle as promptly as we do.

Mr. McCormack.—When I was with the Brooklyn Rapid Transit Company a verdict was given there on account of a contractor being killed on the Third Avenue line, and several witnesses claimed that the car was running 30 miles an hour. The same car was tried and the best speed obtainable was not quite 22 miles an hour.

Mr. Hasbrouck.—Examination of a case will sometimes elicit some interesting facts. I remember one case where a party claimed to be injured for life, having lost a finger. When we got down to the facts we found he was a gambler, and could not handle the cards without the finger he lost; therefore his occupation was gone. (Laughter). I recall a very interesting suit brought against the People's Line of Steamers a good many years ago, where the man made out his case. He was sleeping in the under berth and the man above him broke down somehow and fell upon him, and, as a result, he lost an eye. He got a verdict for $5000 or $6000. The People's Line carried the case up. In the course of two or three years it happened to occur to them that this suit was brought in 1866 for the loss of an eye, and they discovered, on examination of the military records, that this man had been examined for military duty when the draft occurred in 1863, but was rejected because he had but one eye—two years before the accident occurred.

E. G. Connette then read a paper on "How Can We Increase the Efficiency of Employees?" This was published last week.

Mr. Godfrey Morgan.—This paper introduces a subject which has been up at least four times in this association, and once or twice in the National Association, and that is the matter of rules and regulations for conductors and motormen, and the standardizing of a certain form of rules for them. I have discussed this matter with the inspector of the board of Railway Commissioners of the State of New York, Mr. Barnes. He asked me a short while ago if we had a book of rules. I said no; that we had had a number of discussions at the Street Railway Association of the State, at which they were going to take up and standardize a set

of rules for the government of motormen and conductors. I rose more particularly to find out where that resolution had gone and what probability there would be of our ever getting a standard set of rules for motormen and conductors.

The President.—If I remember correctly, this question was dropped on account of objections of some of the small roads to some of the rules proposed because they would not be applicable to them. The fact is, it would be impossible to adopt a set of rules governing the Brooklyn Rapid Transit, the Metropolitan and my little road, as well as some other roads.

Mr. Morgan.—I do not believe the association can make rules; in fact, I would be opposed to a set of rules which would be fit for New York or Buffalo, but would not be applicable to a line like the one of which I am manager. Now, of course, I don't wish to get up a set of rules and have another set adopted by the association put before me, and have to go to the expense of printing this other set later on. If there is any likelihood or probability of any such rules being formulated, I would like to at least know what we are going to do before we get our old rules printed.

Mr. Cooper.—The National Association had a committee appointed and got up a set of rules which we supposed to be a general set. I would like to ask if you know whether the Railroad Commissioners have any idea of formulating a set of rules for this State.

The President.—All I know is that two or three years ago they suggested a set of rules, and further suggested that this association take up the matter, and the outcome was as I stated before. I remember that on account of the difference between the large and small roads a uniform set of rules could not apply.

Mr. Cooper.—Would it not be as well to make it the sense of the association, in the form of a resolution, to ask the Commissioners not to do aything?

Mr. Ely.—The secretary suggested a resolution which, it seems to me, would be a very good way to deal with this question, and for the purpose of getting the matter up on the question, I will offer the following:

Resolved, That the committee to which this subject was heretofore committed be, and the same is hereby discharged, and that the president is authorized to appoint a new committee of five, to consist of representatives from roads in large and small cities and suburban roads, to take this subject under consideration and report to the next convention.

The motion being put to the meeting by the president, it was carried unanimously.

Mr. Vreeland.—I just want to say a word on that rule question. I had more or less to do with it, as there was considerable work done in my office in connection with the matter. We were putting in, at that time, a set of standard regulations. So far as the question of large and small roads is concerned, I was a member of a committee that was appointed to formulate a standard code of rules and train orders for the steam railroads of the United States. We had an engineer come to the East who knew nothing about our train orders or our general methods, and there was a case to be heard in the upper part of this State where there were three railways using one terminal, night and day, and every one of them had a different method of giving train signals with lanterns in the same yards. The same thing occurred over in New Jersey, and it was decided that we could standardize the essential rules for the government of employees. There was an objection made by the small roads at the association meeting, and it was decided that there should be a certain code of rules formulated, running from one to 106, and the same as to train orders, etc.; and that any railway which, by reason of single track or any local peculiarity, required it, could add to any rule. If the rule was No. 80, they could make a rule 80A or 80B, but they could not depart from the regular numerical order of the rules. There is not a railway company in the United States which is not working under those rules. There is not an engineer on the Pacific Coast who could not run under the train orders of the Boston & Maine or Maine Central. The train signals are exactly the same throughout the United States. A brakeman on one road for twenty years can go to another road and have nothing to learn but the local peculiarities.

We have a number of regulations that are general in their character, and would refer to the work of a motorman in any part of the country. It is necessary now, if we get a motorman from any part of the country, to find out how he has been following regulations. Our men took up the subject and made a standard set of rules, which apply on all the roads we are running. You will find throughout the United States that where there are single-track roads the rule is that trains traveling in one direction for twenty-four hours have the right of way. If by reason of the local conditions of single-track roads it was necessary to change that, the change was made by a rule A and rule B, that trains for twelve hours running in a general way had the right of way, etc. We are working under a set of rules now in the Metropolitan. I obtained a set of rules of every large system in the United States, and put a special committee of my men to work on them to pick out what they considered the best and to standardize a set of regulations general in their character. I then gave every superintendent and foreman the right, if necessary, to make changes in those rules. We are working under one set of rules on all our New York properties, and any others around the country under the control of the syndicate.

The next paper read was entitled "Storage Battery; Its Use on Small Roads," by B. B. Nostrand, Jr. This was published last week.

Mr. Nostrand (in answer to questions.—The small engine that we usually operate, running a 60-kw machine, is a simple engine. It just happened so. The other is a compound engine—Westinghouse. The batteries have been in operation since June, 1899. The only expense in the way of repairs have been in the neighborhood of $20. We have had no difficulty with the plates buckling, or anything of that nature. We operate three cars in the morning, and from about noon we run four cars, except on holidays, when we run five cars. We have no arrangement with the manufacturers as to depreciation. We bought outright the batteries without any guarantee as regards depreciation.

Mr. Blizard (of the Electric Storage Battery Company).—In reference to the matter of maintenance, there was a time, when we first started in business, when we had to overcome a very unfortunate reputation the storage battery had made. It was then necessary to give a guarantee, but now we find it is not. We not only guaranteed our batteries, but we guaranteed the men who operated them. Of course, a battery is not indestructible. We have no control over the men who operate the batteries, and there is no reason, under these circumstances, why we should give a maintenance guarantee. The average cost will vary from 3 per cent to 8 per cent or 9 per cent in residential plants, where the batteries are handled by gardeners. In railway service it will run from 5 per cent to 6 per cent. That does not mean that you spend 5 per cent every year, but at the end of five years you may have to spend 20 per cent of the original cost.

The convention then adjourned.

AFTERNOON SESSION

The meeting was called to order by the president at 3 o'clock. The first paper was by Thomas Henning, superintendent of the power house, Buffalo Railway Company, Buffalo, N. Y., and was entitled "Storage Battery." This will be published in the issue of Oct. 6.

The next paper read was entitled "Description of the Rochester & Sodus Bay Railroad" (41 miles), by T. J. Nicholl, vice-president Rochester Railway Company, Rochester, N. Y. This is published elsewhere in this issue.

Mr. Nicholl.—I was asked about the maximum speed that is made, and I will say that I judge it to be about 35 miles an hour. We can make 50 miles, but don't get a chance to get up to that speed.

The President.—I notice that some of the roads are draining their tracks on their own right of way, the same as steam roads. What is the custom of the suburban roads in Ohio?

Mr. Wason.—Where we can, we follow the steam railroad practice. I would like to ask whether the suburban railway managers attempt to keep the weeds out of their tracks? There are advantages and disadvantages in having weeds in your tracks; they do away with the dust but at the expense of your ties.

In reply to Mr. Wason's question on the subject of weeds, it was stated that it was the practice of one road 4½ miles long to trim the weeds down to the height of the rails during the summer and to grub them clean in the fall to prevent catching the snow in winter.

The President.—We have a little road that is grubbing weeds all the while.

Mr. Nicholl.—I have quite a good many miles of suburban road outside of this Rochester & Sodus Bay Railroad, where we have a great deal of grass and weeds, and we keep them down by salting the track. We put several carloads of salt on the track every spring, and that keeps the growth down. It is only about three years ago we started that practice. So far, there are no evidences of deterioration in the rail bonds.

The President.—In regard to draining the track, where we covered it up and the weeds grew, I had to put in new ties, and where we drained it the ties are in fair condition to-day.

Inquiry was made of Mr. Nicholl in regard to his telephone stations along the line, and what method he used for dispatching trains.

Mr. Nicholl.—We have a telephone station wherever we have an agent; that is, at all the villages and at one or two points besides, where we are obliged to use men. For instance, at the car houses

and sub-stations. The form of train orders is very similar to that used by the steam railroads. The train dispatcher gives the order over the telephone, and then has the operator repeat it back to see that he has got it all right, but with the conductor's signature. Of course, we cannot possibly have the conductors coming in and repeating to the train dispatcher; therefore, we rely upon the agent.

The next paper was entitled "Tests Buffalo Railway Power House," by Prof. Norris, Cornell University, Ithaca, N. Y. It is published elsewhere in this issue.

The president then appointed a nominating committee, consisting of Mr. Cooper, Mr. Cole and Mr. Brackinridge, after which the meeting adjourned.

A trip was then taken to the Cold Springs station of the International Traction Company, and later to the Pan-American Exposition grounds, as described last week. The annual banquet was held in the evening, and an account of it was published in the last issue of this paper.

SECOND DAY'S PROCEEDINGS

The meeting was called to order by the president at 9:45 a. m. The first paper read was on "Precision in Steam Power Making," by A. S. Mann, assistant engineer Metropolitan Street Railway Company, New York. Owing to the sickness of Mr. Mann, Mr. Robinson will read the paper. This paper is published elsewhere in this issue.

The second paper presented was by H. D. Cooke on "Compressed Air Motors," and was read by Mr. Himely, of New York. This is also published elsewhere in this issue:

Mr. Thompson (general manager Buenos-Aires Tramway Company).—It seems to me that there is one word in the paper which needs a little explanation, and that is reciprocation. The great thing steam railroads are looking forward to is the substitution of motors for steam. I understand that in compressed air cars there is considerable jolting, which I attribute to the reciprocating action of the motor, and my only reason for rising is to ask the gentleman whether any attempt has been made to employ compressed air in the rotary motors, which will do away with the reciprocating action leading to the jolting.

Mr. Campbell (of the Compressed Air Company).—I would say in answer to the gentleman who asked about the rotary engine, that while they have been experimented with for a great many years, they have never become of commercial value. There is no economy in them; there is a loss. The mechanical engineers have never been able to obtain the same results as with reciprocating engines. As to the question of unbalanced motion mentioned, it depends entirely upon the reciprocating parts; but the lighter the reciprocating parts the nearer we approach to a perfect motion. But where the parts become very much over a 20-in. cylinder, then it becomes a serious matter and causes a hammer blow, while this does not exist in small motors.

Mr. Thompson.—The gentleman has missed my point. The drift of his argument is that it does not affect the structure of the carriage. The question of balancing motors is one upon which every one has an opinion. At any rate, it produces severe jolting. The question of discomfort to passengers is one which relates more to the proportion between the weight of motor and car. In the case of a street car motor, the motor is scarcely too light.

Mr. Campbell.—I can say that in relation to balancing, we have two conditions; these are the weight and reciprocating power. If we move them about, if we take the 20-in. wheel and counter-balance, we have a different result at 20 miles an hour than we have at 30 miles an hour. We cannot counter-balance that perfectly; we can partly. Theoretically, it does exist in any motor, any size, any weight of motor. It exists, but when we come to a smaller motor, the resistance and the effect of vibration is resisted by the weight upon the wheels. It is always the downward motion on the counter-balance that makes the pressure, or what we call the hammer blow; and that is why we have to consider conditions when we come to reciprocating parts; and while I say it does not exist in street car motors, I say it is of such small moment that we do not feel the effects of it.

Mr. Thompson.—Is it not the case that every compressed air motor hitherto made has produced a jolting motion in the car greater than any electric motors?

Mr. Campbell.—Yes, I agree with you that it would be more perceptible than in a rotating motor.

Mr. Thompson.—The compressed air motor is put forward as a competitor of the storage battery; but the only advantage I can see is that it is not so likely to trouble in winter. The practical working objection to the compressed air motor I have always understood to be the jolting sensation produced. In the course of your remarks you said that the rotary motor had not yet been made a commercial success for such small motors as you use on street cars. The only suggestion I threw out was to put the compressed air motor on a more equal footing with the electric motor.

Mr. Campbell.—There is no increase of power in a rotary motor. We have got a fundamental principle in mechanics; it is that in a position a number of pounds moved a given distance determines the power. The difficulty has been in mechanical work in making these positions strike. Again, in getting the extension of same, we have not yet been able to make all joints tight on a rotary engine that will give the best results. We have not been able to operate the extension. For the purposes it has been put to for torpedo boats, economy is no object. It is speed at any expense. If it can be developed it is a very great advantage, and may answer all purposes for a reciprocating engine.

The next paper was by C. F. Uebelacker, of the Elmire Municipal Improvement Company, on "Practical Experience in the Operation of Combined Public Franchises by One Company. Its Advantages to the Public and the Corporation." It was read by Mr. Robinson, and is published elsewhere in this issue.

Mr. Fenner.—Our plant, originally a railway plant, did buy in electric light and power, but didn't find any particular additional expense attending it, so far as the power house was concerned; and we did buy the gas plant, but did not make gas. We bought it under a ten-year contract with Dunkirk, where the gas was made and piped to Fredonia. That is about to run out now. Our power house burned last winter, and we are putting up a new one, in which we expect to manufacture gas, and we expect to manufacture all the gas we need, which will be about 6,000,000 ft. in a small town, with the addition of one man, because other employees can be utilized. In that way there certainly will be great economy, and we can probably make gas much cheaper than if we had an independent plant. If we did not have this property, our combination, which combines a lot of capital, would be valueless. There are not passengers enough, although the fare is 10 cents, between Fredonia and Dunkirk. There are only about a quarter of a million during the year, which would not be enough to pay any return. But with the steam heat we put in, using our exhaust steam, we get about $5,000, which is like found money. Taken all together, it is a valuable plant and the stock is par; but if it were not for the combination the stock would be worthless.

Two papers by R. E. Danforth, superintendent of the International Traction Company, were then presented to the association, one on "Snow Plows," the other on "Rotary Converter Sub-Stations." They will be published later.

The President.—The first topic for general discussion is "Repair Shop Methods, Including Handling and Distribution of Supplies."

DISCUSSION ON REPAIR SHOP METHODS, INCLUDING HANDLING AND DISTRIBUTION OF SUPPLIES

Mr. Nicholl.—I did not come here with the idea of being called upon to make any remarks on a subject of this kind, but in order to bring the matter before the meeting I will say that our plan of handling supplies is quite a complete one. At any rate, we have a book we call our inventory book, which is printed and in the hands of all our employees. It gives a number to every article that we use on the railroad, so that when a requisition is made we only have to put down the number of the article. For instance, every screw has a number, etc. The manner of handling our supplies is this: We have a purchasing agent, who does all our purchasing of every name and nature. Every piece of work ordered, even outside, is made on a requisition to the purchasing agent, so that there may be a proper order for that work or material as the case may be. He has a system of keeping the inventory constantly before him, which is quite a complicated affair, and it would be hardly possible for me to describe it without having the blanks to show you. But it is arranged so that as each article comes into the storeroom, numbering about 2500 in all, it is put on this special sheet for that purpose, under that head and number, and kept up for each day, week and month. On the other side of the sheet is an account of the articles as they go out. We have a box set apart for each kind of supplies.

That will probably suffice to give you an idea of the storeroom. Each foreman of each shop, whether in the armature room, the field room, the truck repair shop, the carpenter shop or whatever it is, makes requisition which goes to the master mechanic for his verification. This goes to the storekeeper, and the articles are issued. Then, each job that comes into the shop, of whatever kind, is numbered, and all material that goes into that job and the labor is charged to that job by the foreman of the shop. In that way we get a pretty good idea of things. Each day we know just exactly what we are doing. In fact, I have a report on my desk every day showing in detail everything purchased and that which has gone out. It serves to keep the office in line. They don't know but that I go over each item. Our repair shops are divided into a carpenter shop, paint shop, machine shop, truck shop, armature winding room and coil room; each one under a foreman, and

all under the master mechanic. Of course, space won't permit me to go into all details, but this will start you.

Mr. Tully.—Our supply department is so very large, and there are so many different kinds of operations, that it is somewhat difficult to describe it. We have over five thousand horses; that means a very large supply department. We have a cable system, which necessitates another system of supplies. Then we have the underground electric, and are now experimenting with the storage battery and compressed air; so that we have five different lines of supplies, three of them very large. Our supply department is one which requires a great deal of attention. I have my requisitions numbered consecutively. I commenced several years ago with No. 1, and I can account for every requisition that has been used; so that any false requisitions that may turn up can be told at once. We check off our bills consecutively on the face of the requisition and copy book. We are just about preparing for a new storeroom. I shall commence in that a card system, keeping an account of material received, etc. I judge from my conversations with the number of railway men who have been to see me, that while we differ in the matter of some details, in the main we are about on the same basis. I report to the auditor once a month.

Mr. Danforth.—Until this year the Buffalo Railway Company reported weekly, but we found we were able to reduce the amount of labor by making monthly reports. At the beginning of the month a list is furnished, having thirty-one spaces, a space for each day, on which the materials issued from stock are entered. The amount issued to each job is marked with the proper date, each day, as the requisitions of the foremen are checked off by a clerk. At the end of the month it is checked up, and a recapitulation sent to the office. We use separate job numbers for mechanical, track and shop work, giving the minor repairs and accounts in the maintenance of those departments a standing job number, which is balanced up every month. The auditor is advised daily of any new work or job numbers issued, with a description of the work. He keeps his accounts by a card system, and can, in a very few minutes, give the management the cost of any piece of work under construction.

The President.—If there is no further discussion or other questions to be asked, we will pass on to the next topic, which is "Selection and Management of Employees, and Methods for Increasing Their Efficiency by Benefit Associations and Other Means."

DISCUSSION ON INCREASING THE EFFICIENCY OF EMPLOYEES

Mr. Vreeland.—In 1881 I was a member of the American Society of Railway Superintendents. Some railways had then had nearly half a century of work, discipline and methods of handling employees. Last Saturday I was requested by the president of the Society of Railway Superintendents to appear before their meeting in October, in New York, and talk on this subject. A committee has been in existence in that society since the early seventies. Men have been changed, other men have worked on the committee. The question of standardizing the time of the United States was a matter of ten years. The question of the standard rules, which this association was going to dispose of for street railway purposes in one year, was up in my early railway days (and I have been in the business for twenty years), and was settled only two or three years ago. It is absolutely impossible to deal with a question of this character without the association, and settle a time for a discussion of each question. Then, if those of you who manage and own railways will say to your employees and your heads of departments who come to this association meeting, "If you can't attend the meetings of the association you can stay home," we will get along very well with this question. It seems to me—and I can speak on this question as a member of the executive board of this association—that it is not fair to the members and president of this association to ask a gentleman who has spent six months in preparing data, to get up and read his paper to a beggarly array of empty chairs. It is not the custom in railway circles of this country. The Association of Master Car Mechanics makes every man sign his name that he was at the association meeting. They do not allow a man to answer for another, and the railway companies keep check of those who attend the session of the convention. The same thing is true of the American Society of Railway Superintendents. There is not a session of that association, and never has been in the past, when every moment is not used for the business purposes of that association. If a man in the room wanted to go downstairs he asked the chair to be excused long enough to go there. And it is impossible for this association to consider questions of a continuous character, unless the members attend the meetings of the association and discuss the questions. A man can get up and generalize on these questions, but I have been working for seven years in street railway circles for the point where we would have some good method for the care and benefit of our employees, and I think we have only started; and if this association can dispose of this matter in ten or fifteen minutes, or one, two or five years, they are decidedly superior in ability to any of the societies of the United States.

The only way to treat the question is as a standing subject of this association. If we want to take it up and discuss it, we must have it stand as a regular topic of discussion of the association. As I said before, it has been before the American Society of Superintendents for twenty years, and this year it is brought up again for discussion. We have had a few words on it for the last few years, but it really has never amounted to anything, as there has been no set time given to it. In the American Society they generally give half an hour to the discussion of that subject in their meeting.

Mr. Clark.—I am quite sure that all in attendance at this session will heartily enjoy all Mr. Vreeland has said in relation to the delegates attending the business session. I know, of my own personal knowledge, that the president of this association and the executive committee have made a determined effort each year to secure at the meeting a large and representative attendance. That they have been successful is evidenced by the increase of attendance each year; but, as Mr. Vreeland has said, it is a deplorable fact that only a small percentage of those in attendance at the convention take an active part and participate in the benefits to be derived from the business meetings, and I think that the president and executive committee will be justified in laying down rigid rules and asking the railways of the State to see to it that their representatives attend the business session.

In relation to the discussion of the very important topics to which Mr. Vreeland has alluded, I would like to suggest if the meeting thinks it pertinent that the subject of "how to increase the efficiency of employees" be divided into several topics or divisions, to be arranged by Mr. Vreeland, and that the president of this association allot to the representatives of the different railways throughout the State such of these topics as he thinks would be most applicable to the situation and geographical location. I think the matter can be taken up in this way so that next year it can be considered as it should be, as it is of vital interest to railways as well as to the country at large. Therefore, I offer the following resolution:

Resolved, That the topic of "How to Increase the Efficiency of Employees" be separated under different heads, to be suggested by H. H. Vreeland, of New York, and that the president allot to the various street railways throughout the State the various sub-topics suggested, and that the representatives of the respective roads prepare to discuss same at the next annual meeting.

Carried unanimously.

The President.—The next topic is "Pavements."

DISCUSSION ON PAVEMENTS

Mr. Cole.—I saw in the papers that Mr. Boyle had a long litigation at Utica, and I wanted to know what the decisions were in those cases. It was largely a case, I think, where they were going to pave with asphalt, and the franchise of the Utica Belt Line stated that where the railways were laid should be paved with a pavement in every way suitable for street railway purposes. The claim was made by the engineer of Utica that asphalt was not suitable, as the concrete overlying the tie caused a vibration, and this vibration separated the pitch from the concrete so that the water trickled through. There was also a recent decision in which the courts determined that the 2 ft. of pavement to be laid outside the rails really meant 4 ft. I wanted to know whether such a decision had really been rendered.

Mr. Nicholl.—I have had a good deal of trouble with the paving question, and I have been trying to get an opinion on that 4-ft. matter. With us it is 2 ft. on either side of the track, and I don't think there has been any decision to the contrary.

Mr. Cooper.—I was told by an attorney the other day that the matter had been decided by the courts, but it was a decision which was subject to reconsideration by a higher court; that it meant 2 ft. on each side of the track. That decision was made last week.

The President.—If there is no further discussion on that subject there is another question we have been asked to talk about, viz.: "Snow Plows."

DISCUSSION ON SNOW PLOWS

Mr. Danforth.—I suggested that this question of snow plows was of great interest to the operating men of this State, and one which could stand considerable discussion. We do not all agree as to the best form of plows, or the best method of operation. It is only a few years, within a decade, that our plows were anything more than a walkaway or scraper. Last winter, in this city, thirty of our plows were levered, placed diagonally across the track under the wheels, and run by electric motors placed in the cab. We have been slowly arriving at the conclusion in this city that this plow is a very pretty affair, but for handling the snow is not what we want. A few years ago, the Thomson-Houston Company

got out a sweeper. The Buffalo Railway Company purchased two. These sweepers were equipped with steel brooms. While the motors last these sweepers are as fine a machine for city work as can be obtained. It is impossible to spoil them; they will cut anything short of hard ice. They fail in a large drift because of the inability to throw the snow over the sides of the bank. A few years later Captain Ruggles, of Charlotte, devised a rotary plow. He met with fair success and we tried one in Buffalo. The first was rather crude, but we managed to go through 13 ft. of snow; not rapidly, but more rapidly than with shovels, and with less expense. The following winter the Buffalo Railway Company and other lines built rotaries somewhat heavier and double-ended. These rotaries are still being used by this company. We find that in heavy work and deep drifts on the suburban line, and particularly on lines running north and south, these plows are invaluable. They fail in heavy wet snow, as may be imagined, from mechanical defects, not from the fact that the scheme is not right. We have slowly got around to the idea that a snow plow, to be effective in city work, must have traction. We therefore, last winter, built thirteen-ton, four-wheeled plows; double truck share plows. We placed on these what we supposed were pretty fair flangers. In December the men operating the roads in Western New York had a wet snow before the frost entered the ground. The result was rather disastrous for some of us. The rails, after 6 ins. of snow had fallen, became chilled; wagons and sleighs got in ahead of our cars, squeezed out the water, and there was an inch of ice on the rails. Our light plows were useless; our sweepers would not touch it. Our heavy plows went 100 ft. and then into the gutter. We squirmed out of the difficulty by using rather a unique flanger. Our life guards are so constructed that they are hung to a ring on the platform—an eye rather. We took our switch irons and dropped them through the eye and in front of the back cross piece of the sweeper, and placed a man to rip out the ice as they went along. Later, when 18 ins. of snow had fallen and the light plows had become crippled, this section of Main Street was covered with 15 ins. of snow, pushed down by the sleighs, and no cars or plows on the street, our rotaries happened to be working on outside lines where we could get hold of them. In thirty minutes they were down here, and in another twenty minutes the lines were open. They picked this snow up, tight as it was, and I am sorry to say in some instances broke a few windows. The people in Buffalo knew nothing about the threatened tie-up. When they got up the lines were running beautifully. Later, when we were visited by 4 ft. of snow, our share plows proved invaluable. The levelers were useless after the first 2 ft. had fallen. These heavy share plows, without pushing, kept the lines open and the cars very close to schedule time. They demonstrated their value to us at that time very nicely. Within the next four or five days, when the wind commenced to blow up drifts on the suburban line and these drifts had time to become hard, we found it impossible with a 25-ton, four-motor equipment behind a 13-ton plow, to make any headway through these drifts. We brought out our rotary plows, and while they went, perhaps, only a mile or mile and a half an hour, they went through the drifts. That proved to us conclusively the particular service for which our rotaries could be used. Following this, we have this year constructed heavier double-truck share plows, following practically the same lines in the matter of construction as the year before. A few years ago, as an experiment, we bought a rattan sweeper. I put it on one of the inside lines where the service was heavy, so that there would be plenty of grass and not too much sand to handle. We put it in the hands of the best inspector we had, and asked him, as a special favor, to make a success of the sweeper. At the end of the month he wanted to be relieved of his position. He said he would rather have two 6-ton passenger cars any day than that sweeper. We shunted it onto another division with the same result. The man did not know how to handle the sweeper, and I would like someone to tell me.

Mr. Reed.—The handling of snow varies according to local conditions. The rotary plow, while very valuable on suburban lines, would raise a howl in New York City. Our snows are not, as a rule, very deep. We use the rattan sweeper. The first year we had some trouble because the sweeper itself was not constructed satisfactorily. We run them frequently, otherwise we would not run them at all. In the heavy snows we keep sweepers on not more than ten minutes headway. I have some share plows, but they have not proved successful. We follow up the sweepers with the old-fashioned walkaway, drawn by horses, to keep the snow back from the track as far as possible. In the storm of two years ago, which was the first storm we had to contend with on our underground system, we ran our cars at rather irregular intervals until, I think, about 5 o'clock Monday afternoon, when we were tied up by the conduits filling. After being tied up, it became a matter of shoveling the snow, for which we fortunately had about seven thousand men to call on. We use the electric sweeper entirely upon the electric roads, reinforcing it with the old-fashioned walkaway. We do occasionally have to use on switches, etc., hand power to keep the snow back far enough so that the sweepers can work properly. Last winter we had no trouble whatever, and never have any trouble except when our conduits fill. Nor had we at that time a sufficient number of sweepers. We immediately got other sweepers and share plows, but I do not think a share plow was ever made that was of good service. We keep a good supply of brooms on hand. We have never used the steel brooms at all.

Mr. McCormack.—Our experience with the snow plows that manufacturers give us, a four-wheeled car plow, is that it is hard work to keep the front wheels on the track. In Brooklyn we made a suggestion to the manufacturers which largely obviated that trouble, by putting a lever just beside the rear wheel, so that the force against that would help keep the front wheels on the track.

The committee on nominations then reported as follows:

President, G. Tracy Rogers, Binghamton.
First vice-president, John Boyle, Utica.
Second vice-president, Edward G. Connette, Syracuse.
Secretary and treasurer, Henry A. Robinson, New York.
For executive committee:
G. Tracy Rogers, Binghamton.
Herbert H. Vreeland, New York City.
Clinton L. Rossiter, Brooklyn.
T. J. Nicholl, Rochester.
W. Caryl Ely, Buffalo.

These nominations were elected unanimously.

Rochester was selected as the next place of meeting.

At the close of the meeting a trip was made of the cars of the International Traction Company to Niagara Falls, and thence to Dufferin Café on the Canadian side, where lunch was served, and the party enjoyed the view of the upper rapids. Thence the party left for Queenstown, and crossed the lower suspension bridge to Lewiston, returning to Niagara Falls by the Gorge Route, after which they were taken to Buffalo. The trip, which stands unrivaled for beauty of the natural scenery presented, was heartily enjoyed by all, who unqualifiedly expressed themselves as heartily appreciating the hospitality of the International Traction Company.

Practical Experience in the Operation of Combined Public Franchises by One Company *

BY C. F. UEBELACKER

The combination of public service enterprise is the rule of the day. We are all more or less familiar with such combinations as street railway and electric light, or electric light and gas, or, perhaps, all three under one ownership and more or less under one management. We say it is a good thing, that large economies must result, etc.; but when we come to look into the details of organization it is less evident just where the large savings are to be realized. We will leave out of the discussion entirely ornamental office holders on fancy salaries. The constant demand of the public for decreased prices and increased facilities is rapidly replacing them with the working president and treasurer. Combinations are not necessary to achieve these economies.

The advantages which do exist and which are the direct outcome of combination must be divided into two classes.

First.—Those affecting the income.

Second.—Those affecting the expenses.

Of the first class the most prominent is the decrease in losses from bad accounts resulting from service charges all passing under the eye of one manager and through the hands of one set of accountants. Railway business being on a strictly cash basis, is little affected. The income from lighting charges is first relieved from much of the drain of unpaid accounts, and second increased by the absence of the necessity for annoying many applicants for service with the demand for a deposit. The requiring of a deposit gives offense to nine out of ten applicants. It brings forcibly to their attention the fact that they are dealing with a monopoly and this is to the small customer the same as the red rag to a bull. He becomes immediately insulted because his honesty is doubted, and not infrequently ends with the statement: "Well, if I've got to put up that deposit to get it I don't think I want gas," and goes out of the office explaining to whoever happens to be in hearing that the only way for the down-trodden to obtain their rights is for the city to own and operate the gas plant.

The ability to grant concessions in one class of service to obtain

* Paper read before the New York State Street Railway Association Sept. 19, 1900.

additional custom in others is of great advantage to the management in dealing with large consumers. Many an important deal turns up some small pique or fancied wrong of the customer in his dealings with the public service corporations, and a small concession to this feeling will frequently accomplish more than a plain demonstration of saving in expense, or an improvement in facilities.

The consolidation of the influence of several corporations is another great advantage in obtaining business. The trade of the companies themselves in the different lines is a large factor in the town in which they are located, and when there is added to this the trade and influence of the companies' employees, the result is generally the most powerful concrete influence in the whole town.

Last of the first class of advantages is the absence under combined management of a whole host of small jealousies and conflicts between the managements of the different companies when they are separately operated. The common use of the street by all public service corporations is a frequent source of complications. The gas company wishes to repair a main which lies under one of the railway company's tracks. The gas people wish to stop waste that is going on and the railway does not want to lose the use of the track a single day. Even supposing that an agreement is reached without a lawsuit, there is still the trouble that the gas company will want to do the work in the summer, just the season when the railway can least afford to have its services interrupted. If the railway manager comes out on top (he usually does) the gas manager will feel somewhat put out, and sooner or later will either use his influence against some scheme of the railway, or what is equally undesirable, he fails to second it. Under the combined management this source of loss should disappear entirely. The money all goes to one account, and it is only a question of judgment and a few figures to determine which of the conflicting interests is the most important.

Turn now to the other side of the question, the economies of combination. There is quite, or nearly the same, amount of work to be done in the companies combined as in the same companies separate. The railway must run just as many cars, the electric light company must turn out just as many kw-hours. There are undoubtedly some few operations which are duplicated in the companies separated, such as inspecting and meter reading; the bulk of the work, however, is unaffected by the combination. It is there and must be done and paid for just as much as before. The economy does not lie then so much in the reduction of labor as in more fully using the full time and ability of each man employed.

First of all comes the concentration of responsibility. Each plant is just as much in need of a superintendent as ever, but where before that superintendent was either actually or in effect the business manager as well, his position now becomes a purely technical one. If the same man is retained after the combination as before, his time is now fully devoted to the technical side of his plant, and he should introduce economies there which he was too busy to see to before. If a new man is decided upon, technical ability alone is required, and this is much more readily obtained alone than combined with business experience.

Another class of labor with which we are all familiar and which can be reduced by combination is the "necessary" man, the man for whom we are constantly finding something to do so as to have him on hand for certain intermittent work.

The street departments of all public service corporations always contain some men of this class. The railway retains its track foreman, the lighting plant its line foreman, the gas company its tapper, and others of the same class. After combination much of this work can be thrown into one street department, thus reducing this class of permanent employees to a minimum.

The economy in the combination of the railway and lighting power houses is self-evident. The addition of the necessary machines for generating the railway power necessitates no increase in the watch force at the plant. The whole increase in running expense is the coal and repairs required for the railway machinery. By the use of double-end generators, in fact, the combination of the railway and lighting loads can be effected with a considerable economy in both first cost and coal consumption.

The peaks of the railway and lighting loads seldom if ever fall at the same time, so that the machines required for the peak on the railway can also serve to carry the lighting load over its peak.

In the office the amount of work can be somewhat reduced by having accounting systems of the different departments uniform and by uniting the accounts of all parties from whom material is purchased for the different departments in one purchase and sales ledger, ruled with a debit and credit column for each department. This book brings all the various small personal accounts outside of the service ledger together, and much reduces the clerical labor, especially in checking up and vouchering the small local bills. Still further economies in office labor can be accomplished by combining the bank account and voucher system, but these are so perfectly evident that it is useless to go into them in detail.

The saving in the amount of money locked up in stores is also quite a large item in the advantage of combination. It is self-evident that of such articles as are used in common by the various departments a much smaller surplus is necessary for the several departments run as one company than where each department is run by itself without reference to the others.

To sum up the foregoing, when companies, previously well managed, are combined, the advantages and economies lie not so much in broad, sweeping reductions as in the attention to the smaller details of the combined organizations. The advantages lie not so much in the line of actually reducing the whole amount of labor required to accomplish the combined result as in the economical division of that labor. The use of the whole instead of a portion of each employee's time and assignment of similar work in different departments to the same employee accounts for reduction in operating expense much more than the reduction of the actual amount of labor required for the production of the product.

Compressed Air Motors

BY H. D. COOKE

Compressed air for street railway operation is the subject assigned to me for treatment in this paper, and I find it difficult to place all the facts for an intelligent consideration of this subject before this convention in the twelve minutes allotted.

The question of liquid air was also coupled with this subject, but I do not deem it necessary to touch on this question more than to say that nothing has yet been accomplished in the manufacture of liquid air which will warrant its consideration as a factor in the operation of street railways at this time. The present method of its production is to start with compressed air at 2000 lbs. pressure, and by expanding many volumes of air at this pressure, thereby producing intense cold, to liquify a small volume of air. The only advantage which liquid air has is the small form in which it can be stored, 800 ft. being compressed into one, but, on the other hand, as in this form it is the ice of air, the additional cost of heat necessary to return it to ordinary air for use in cylinders, adds unnecessary expense. In other words, you cannot get out of a thing more than you put in it, and the expense in this case is prohibitive.

The subject-matter of our theme, therefore, will be confined to the latest and most improved compressed air cars now in actual service in three cities of the United States, which are started, kept running and stopped by compressed air. When it is considered that one of the earliest applications of air in railway service was its use for air brakes as a stopper of trains, it is passing strange that its use as a starter and operator of trains did not earlier occur to mechanical minds.

Space precludes any general review of the past history of air except to state that it was one of the earliest known of what may be termed the secondary forces or powers. Authentic records of the application of air are found among the writings of the Alexandrians, 300 years before Christ, and, later, water was used in connection with steam, but not much progress was made with either of these until the present century, during which such advances have been made in the manufacture of iron and steel, which have been used in the construction of engines, boilers, tubing, etc., as to make the use of steam the most important factor in modern life.

Although the application of compressed air to the propulsion of vehicles is of comparatively recent date, the fact that it is used in practically the same way as steam gives it the benefit of all that has been done in the way of the perfection of the steam engine. In fact, there are many instances where steam boilers have been charged with compressed air, and engines operated therefrom, and in one instance a locomotive was charged with compressed air and run about the railroad yards and used for switching, etc. For such purposes, however, specially designed machines are better.

Limited space precludes any but the most general review of this important subject, and certainly nothing is more important to street railways than the question of a power which can be economically applied to all conditions of service, and which is of so simple a character as to make its operation and maintenance equally economical. Recently, however, it has been given serious consideration, and all the claims made for it have been fulfilled. It has proved itself reliable, unchanging, and where it has once performed a service it has always, under the same conditions, con-

* Paper read before the New York State Street Railway Association Sept. 19, 1900.

tinued to perform that service. Unlike steam, compressed air does not have to be used as it is generated. It can be stored up, and is ready for use when needed. Compressed to any required degree, it will always return to its normal atmospheric density.

Briefly described, the construction and operation of an air car is as follows:

The most approved form of motor now in use in this country, and of which a number have just been constructed for the Metropolitan Street Railway Company, of New York, for its crosstown lines, consists of two small reciprocating engines underneath the car body, each connected directly to one pair of the car wheels, according to the most approved form of locomotive engineering practice. The pair of wheels so driven is connected by parallel connecting rods to the other pair of wheels, thus making all the wheels under the car drivers. The air, before passing into the cylinders of the engine, passes through a reheating tank of water, heated to an initial temperature of 300 degs. The reheating of the air before use returns to it all, or a very great portion of, the heat units which were taken from it during compression. To illustrate this, a test was made of a motor in Rome, N. Y. This motor, which carried 35 cu. ft. of storage, was run with cold air, until all the air was exhausted, and covered only 8 miles. Afterward, the same motor was run, using the reheating apparatus, and 15 miles were covered. The heating of the water in the tank is done by attaching a steam connection directly from the boilers which furnish steam to the compressors, to the reheating tank on the motor, and passing the live steam into the water.

In order that the minimum amount of difficulty might be experienced by the average motorman, a controller was devised, which, in appearance and operation, is very like an electric controller. An air brake is one of the features of these motors, and an ingenious contrivance in the way of a starter, is also controlled by the brake handle. The valve motion is exceedingly simple, and gives a range of cut-off of from 1-10th to 5/8ths of a stroke. There is no appreciable exhaust, and the operation of the motors is practically noiseless. The air brake used on these motors is operated from air stored on the car, and is absolutely noiseless, both in its application and release. Being operated by the same handle which starts the car, there is no danger of the motorman leaving his brake on and trying to start the car at the same time.

Cars of this type are in their sixteenth month of operation on the North Clark Street cable line in Chicago, doing the night or owl service on that line, and sometimes hauling two trail cars. During the severe winter weather and snow storms which prevailed in that city last winter the compressed air cars were the only ones to perform their regular schedule. Compressed air cars have been in use in France for several years, and also in Switzerland, and in some places in those countries are used to haul two and three trail cars, but the American motors are pronounced by both our own engineers, and engineers from other countries, to be far superior to those of European manufacture.

The storage tubes under the car are of mild steel, capable of withstanding a pressure of 5000 lbs. to the square inch. Bottles of this character are used, both in the power house and on the car; the initial pressure in the power house being about 2500 lbs., and on the cars about 2000 lbs., which pressure on the cars is, by means of a reducing valve, reduced down to about 150 lbs. to the square inch before going through the reheating tank, and thence passing into the cylinders. It will be seen, therefore, that there is an ample factor of safety allowed by the storage tubes, and all precautions which can be are provided. It is apparent that the farther the cars travel the greater the factor of safety becomes. The storage on the car is underneath the seats, or the car floor, and the cars, in appearance, resemble the standard Broadway, New York, cars, none of the storage or machinery being in sight, and no paying space being taken up by either.

We now come to the power house: Air compressors, driven by an economical stationary steam engine, or by water or other power, compress the air from atmospheric to 2500 lbs. pressure to the square inch, and as the air is compressed, it is stored in a battery of steel bottles of the character of those above mentioned. During compression, however, great heat is developed, and a system of water jacketing is used which reduces the temperature of the air to that of the surrounding atmosphere. By means of a special separator all the moisture contained in the air is separated from the air as it passes from the compressor to the storage, thus securing perfectly dry air. It is well known that expanding gas or air develops an exceedingly low temperature, but the use of the separator, removing all water from the air before storage, obviates freezing upon expansion, and the passing of the air through the hot water before use in the working cylinders restores to the air the heat units which were taken from it during compression, and also furnishes enough moisture in the form of steam to assist in lubricating the cylinders. The exhaust from the engine cylinders never falls below 70 degs.

In order to recharge the storage on the car it is only necessary to connect the storage in the power house with that on the car, and equalize the pressure between the two. This is usually done at the end of a run, and while the car is waiting, and takes about two minutes. In Chicago, however, this is done on the street, and while the car is on its route, and has never caused any delay or stoppage of the service, even though done while the air cars were running between cable trains.

During the last four years experimental and actual demonstration of air cars in the service have reasonably determined the following facts, viz.:

That the cars operated in Chicago during a period of six months consumed an average of 409 cu. ft. of free air per car mile, and that the cost of maintenance of these motors is much less than that of the ordinary steam engine, as there is no boiler to be cared for.

We have been furnished figures by the most responsible builders of air compressors in this country, estimating on a volume of 6800 cu. ft. of free air per minute, which should be sufficient to operate one hundred cars, which show that 2.8 cents will compress 1000 cu. ft. of free air to 2000 lbs. pressure. This estimate is approximate for local conditions, and coal is figured at $2.90 per ton for a twenty-four hours' service, taking 2 lbs. per hour for indicated horse power. This includes attendance of engineers, helpers, firemen and laborers, and also for oil and waste, and allows for 10 per cent per annum for depreciation.

It is believed that compressed air cars have a place in every large system already installed, whether cable or electric, either for performing night service where it is not advisable or economical to run a large plant for the operation of a small number of cars, or where feeder or crosstown lines are necessary, and the installation of the overhead or underground trolley would not be permitted.

In brief, the advantages of compressed air for the operation of street railways may be summed up as follows, viz.:

1. A system of independent motors, which, after receiving their charges, do not rely upon the power plant, and which will always finish their run, should anything happen to the power plant; which also do not need any special outdoor construction, either underground or overhead, with the attendant cost of maintenance.

2. Slow moving machinery, both in the power house and on the car, which is easily maintained.

3. Opportunity for charging cars, and storage in power house, during light hours, for use during the rush hours.

4. Spring-supported motors and load, doing away with excessive jarring and pounding on the track, and thus greatly prolonging the life of the roadbed, the life of the motors, and contributing to the easy riding of the cars.

5. Low first cost of plant; low cost of maintenance, and opportunity for making repairs and adjustment without stopping operation of cars.

6. Freedom from liability of delay in transit from snow, ice or sleet.

Storage Batteries in Railway Power Stations *

BY PROF. H. H. NORRIS, CORNELL UNIVERSITY

Within the past few years more attention has been given to the refinements of station operation than was possible at the time of the rapid change from horse and cable to electric traction. By the use of the many engineering devices now popular the coal consumption in stations supplying power to electric railway systems has been reduced to a very respectable figure, not greatly exceeding 4 lbs. of coal per output horse-power in first-class plants. This accomplishment is remarkable when the nature of a railway load is taken into account. This load fluctuates greatly in two ways: First, from instant to instant, especially in small roads, and also on account of the variable nature of the business during certain hours of the day. These fluctuations tend to prevent economical operation of engines, boilers and generators, while the "peaks" and the extremely light loads reduce the load factor of the station.

Careful selection of sizes of machinery tends greatly to economy, but there has long been felt a need for an automatic regulator of the load which should be economical and convenient. The storage battery has always been considered a theoretically ideal device for the purpose, but patent litigation and other difficulties interfered with its commercial development until quite recently.

FINANCIAL FEATURES

The financial features connected with the application of the storage battery to railway work form the determining factor in their use. There is no doubt, from an engineering standpoint, that

* Paper read before the New York State Street Railway Association, Sept. 18-19, 1900.

they are a success. They have not been in use in this country in railway work for a long enough period to determine absolutely their depreciation, but apparently this does not amount to much more than that connected with moving machinery. The experience of a number of large users of the storage battery has been obtained, and during the short periods in which the batteries have been in use, practically no money has been spent in repairs. The oldest battery of which data is at hand, has been in use five years, but most of the batteries have been installed within two years. The depreciation which one of the largest manufacturers figure upon is from 2 per cent in the best managed stations to 8 per cent in small plants considerably overworked. Six per cent they consider to be a conservative figure under reasonable conditions.

The first cost of a battery is considerable, being, in average size plants, not far from $100 per kilowatt output when discharged in one hour. The same battery will have a much larger capacity when discharged more slowly. In order to obtain a general idea of the proportion of size of battery to capacity of station, data was obtained from a number of well known plants. Out of the station capacity of 43,560 kw the battery installed had a total capacity of 28,560 amperes for one hour, or an average capacity of two-thirds of an ampere hour per kilowatt output. Assuming a capacity of station of 1000 kw a battery of 666 amperes output for one hour would be chosen. The exact amount varies with the nature of the work demanded of it. For "peak" work a larger battery would be needed than merely for regulating work. If a battery of 270 cells were used, assuming an average pressure of two volts per cell, the cost of such a battery at the above figure would be about $35,950. At 6 per cent depreciation and 5 per cent interest, the annual cost of this battery would be about $3,955, exclusive of booster, attendance and building. The booster is necessary if a close regulation of voltage is desired, and the cost of such booster is between $50 and $150 per kw. If the booster produces a pressure of 50 volts its capacity is about 9.25 per cent that of the battery, so that its price in the above illustration would be somewhere between $1606 and $4818. Assuming depreciation on booster at 8 per cent and interest as before, the annual cost of booster would be between $21.20 and $63.60 per year, the exact amount depending on local conditions. Attendance usually involves no extra expense as the regular employees of a station are able to give the necessary amount of time without interfering with their other regular duties.

Cost of extra building is a purely local matter, and amounts to very little except in the case of large buildings, as some spare room is to be found about most stations. To offset the extra expenditure due to the use of the battery, there should be a considerable reduction of expenses in operating the boilers, engines and generators. This saving should result from the increased efficiency of the apparatus due to more effective loading; to reduced depreciation on machinery from the same cause; to the saving of wages through shutting down of plant during light loads; to the saving of copper in the lines when the batteries are installed in sub-stations, and other reasons following from these. The almost universal testimony is that the saving more than counterbalances the increased expense, and that, therefore, the battery is an economical adjunct to a railway power station.

ENGINEERING FEATURES

Viewed from the engineering standpoint, a storage battery serves a number of very useful purposes in a railway station or sub-station. First, by reducing the fluctuations of the load, thus allowing the machinery to be operated under more advantageous conditions. Second, by acting as an energy reservoir for the supply of excessive drafts of power, and thus permitting the installation of a smaller number of units than would be otherwise necessary. Third, by placing the batteries in sub-stations the pressure over the system can be made more uniform, for the battery will be charged when the draft of power is small, and discharged when this becomes excessive. Fourth, by drawing upon the battery at times of very light load the machinery can be often shut down and the load operated from the battery alone. This feature is especially applicable to small stations, when the night load is very light and where accidents to machinery often cause annoying shut-downs.

The use of an energy storage reservoir is common in many applications of mechanical laws. For example, in the steam engine the fly-wheel absorbs the energy supplied very irregularly from the piston. If the load on the engine be steady, the fly-wheel regularly absorbs energy when the piston pushes more strongly than is necessary, and gives out enough to supplement the effort of the piston when this falls below the amount required to overcome the resistance of the load. The pressure on the piston may vary from 100 lbs. per sq. in. at the beginning of the stroke down to 5 lbs. or 10 lbs. at the end. Through the medium of the fly-wheel this effect is averaged and may deliver a steady effort equivalent to a uniform pressure of, say, 40 lbs. per sq. in. on the piston. If it were not for the inertia of the moving parts, the engine would stop before the load reached the average value of the piston effort. Still more so is this true when the load also is irregular. Here, the fly-wheel acts as a buffer between the variations on both sides.

It is exactly in this way that a storage battery neutralizes the fluctuations in the current of a circuit when connected in parallel with it, for it absorbs energy and stores it in chemical form when the load is light, and restores energy to the circuit when the load is heavy.

It is in "peak" work even more than as a regulator that a storage battery demonstrates its utility. It is certainly uneconomical to install machinery which will operate for but a few hours each day. A heavy draft of current from a battery will not injure it materially, so that a small battery will carry a very heavy load for a short time. It does this at a reduced efficiency, but the loss in energy in the battery does not amount to as much as the saving effected. W. E. Harrington, general manager of the Camden Suburban Railway Company, of Camden, N. J., states that a reduced coal consumption of 23 per cent; an increased capacity of station of 300 amperes on account of a more economical load upon the engines; a material reduction in expense for repairs upon machinery, are some of the results of the installation of a battery in his plant. The capacity of the station is 1615 kw, and the battery has a capacity of 300 amperes per hour, somewhat below the average stated earlier.

John Murphy, general superintendent of United Traction Company, of Pittsburgh, Pa., reports curtailed operating expenses equivalent to 24 per cent of cost of battery.

The use of batteries in sub-stations, particularly where the distribution of power is accomplished by the use of alternating current at high pressure and rotary converters, results in very high economy. The rotary converter is loaded uniformly, so that its highest efficiency can be maintained, and thus an efficient supply of power is at hand directly where it can be used to the best advantage. Rotaries are used with great satisfaction in the Buffalo Railway Company, of Buffalo, N. Y.; the Rhode Island Suburban Railway Company, of Riverview, R. I., and many others. In the immense system of the Metropolitan Street Railway Company, of New York City, twenty-one 1000-kw rotaries will be used. W. A. Pearson, electrical engineer of this company, states, as the benefits due to the use of the battery in this connection, that it "decreases the load variations at the different stations, gives us reserve to fall back upon at times of heaviest loads, and allows us to shut down sub-stations for work on high-tension wires and on steam plants at hours of lightest loads."

The ability to shut down a station for even a few hours a day not only effects a saving in running expenses, but it allows time for repairs and inspection of machinery. It is better for the men, as it shortens the hours of labor, and it is better for the station. In addition to the matters already mentioned, the battery is of great assistance in enabling the generating units to be kept fully loaded, as the load increases and decreases. In fact, in very large stations this is one of the principal uses of the battery. It is the custom to install several generating sets and to start and stop them as the load demands. Without the battery the load on the different units would be fluctuating, but with the battery the latter furnishes part of the power until it is found economical to shut down a unit, and then it gives out power until the load has fallen to about one-half the capacity of the unit next to be shut down. The reverse of this is true with an increasing load. This point will be brought out more fully in the discussion of the Buffalo Railway plant.

A most important feature of storage battery installation is its use in line work. It is a well known fact that the average power carried by a line is very small in comparison with the occasional heavy demands: Thus, if a line be designed for a given drop with the average current, the drop with unusual drafts of current will be excessive, which naturally occurs when the pressure should be highest. To put enough copper into a line, especially when the latter is long, is impossible from a financial standpoint, so that a compromise has to be effected between excessive drop and financial economy. It is the emergency drop that has to be looked out for. Just here the storage battery is very effective. By locating it at some distance from the station the battery is charged rather uniformly from the line. When a heavy draft of current occurs, instead of an excessive drop in the line the battery furnishes most of the large current, and thus the drop is only the natural drop of the battery between charge and discharge. In one case the installation of a $10,000 battery was stated by the engineer to have saved $30,000 worth of copper. Although the depreciation in copper is less than that of the battery, it is not enough less to offset this saving. Still other uses of the battery

might be mentioned, but most of these follow as a consequence of the advantages described.

BATTERY OPERATION

The beneficial effects of a storage battery are largely dependent upon the treatment which the battery receives. The battery has two purposes; first, regulation, and second, preparation for emergency. In the first case the battery can be handled for economy much more easily than in the second. In anticipation of an emergency, such as a heavy peak in the load curve, or the possibility of a "shut-down," the engineer will naturally over-charge his battery in order to be sure that it contains the maximum possible quantity of energy. Overcharging necessarily involves a waste of energy, so that the battery will appear less efficient.

In regulating work the battery is most economical when it is about three-quarters fully charged. This is true for the following reasons:

In charging and discharging there are two main sources of loss of energy; first, the loss in ampere-hours due to overcharging, and second, to the loss in pressure, both in charging and discharging, and local action caused by the resistance of the battery and connections, and by local chemical action. The second loss is much greater when the battery is nearly fully charged; hence the desirability of keeping the charge below this amount. Three-quarters full is found to be about the best amount. These losses can be made a minimum by careful handling, as will be brought out in the illustration from the Buffalo plant.

THE BUFFALO PLANT

In order to illustrate the principles described in the first part of this paper, a well known and representative plant will be discussed in some detail, with a description of elaborate tests made upon it by students of Sibley College, Cornell University, during the past spring. The stations of the Buffalo Railway Company have been fully described in the "Engineering Literature," in which additional details can be found. The tests were made at the Niagara Street station, where power is obtained from a steam plant and from Niagara Falls. This station is now shut down and undergoing extensive alterations in order to utilize still more completely the Niagara Falls power, the experience with rotaries having been so eminently satisfactory.

The boiler equipment consisted of four 250-hp Babcock and Wilcox water-tube boilers, twelve 300-hp same make, and two 300-hp marine boilers. The supply of fuel was as nearly automatic as possible, as an electrically operated elevator took coal from the dump near the railway to a coal pocket of 2500 tons capacity immediately behind the station. A second conveyor, electrically operated, raised the coal to the top of the boiler room, where a horizontal conveyor carried it to a 5-ton hopper. A second movable hopper, of 1-ton capacity, distributed the coal to the Roney over-fed automatic mechanical stokers.

This portable hopper enables a very complete record of coal consumption to be kept, by recording the number of times which the hopper is emptied.

Removal of ashes was accomplished by running a hand-car in a tunnel below the hopper-shaped ash-pits and emptying the ash-pits about twice a day.

Feed-water is supplied either from the Niagara River, which is the normal arrangement, or from the city supply in emergencies. The water for the boilers is drawn from storage tanks of about 3400 gals. capacity each, through feed-water heaters. These tanks are supplied from the hot well of about 310-cu. ft. capacity. The water in the storage reservoirs is kept at about 50-lbs. pressure.

The engine equipment consisted of eleven engines, all two-cylinder cross-compounds, as follows: Two horizontal automatic Ball engines of 250 hp each. Nine vertical marine Lake Erie engines, three of 1000 hp each, and six of 500 hp each. To each of the three 1000-hp engines a ten-pole, 800-kw General Electric generator was directly coupled. To one of the Ball engines a 200-kw Edison bipolar machine was belted. Two generators of the same type were belted to three of the Lake Erie engines and 200-kw four-pole General Electric generators were belted to each of the other three engines.

A notable feature of the engine room was the rotary equipment. Four six-pole three-phase, 500-kw rotary convertors took alternating current from the secondaries of transformers at 350-volt pressure, three-phase. The primaries of these transformers are fed at 10,000-volt pressure from the Niagara Falls power plant. The rotaries convert the alternating current at 350 volts into a direct current at a pressure of about 550 volts.

The storage battery equipment of this station was a very large and complete one, having a capacity of 3000 amps. for one hour, and consisting of 272 cells of the "Chloride" type. As auxiliary to the battery a 70-volt booster, capable of passing 3000 amps. or more, was connected between the positive side of the circuit and the ground. The purpose of the booster was to force the battery to discharge when the load was heavy, and to force it to accept current when the load was light. This was accomplished by raising the battery voltage in the former case and lowering it in the latter.

The station was supplied with all necessary modern auxiliaries which go to increase the economy of operation of such plants.

RECORDS AND TESTS AT THE BUFFALO RAILWAY COMPANY'S PLANT

In the station just described very careful records of station performance were kept. These included readings at ten-minute intervals of voltage, total current output and generator-current output. Also, the daily coal consumption, number of boilers in use, wattmeter readings and weather conditions were recorded.

The conditions under which the plant operated were peculiar. A certain amount of power was purchased from the Niagara Falls Power Company to be used continuously. Also, the large number of cars constantly in operation made the load on the station remarkably uniform. These facts should be kept in mind in analyzing the results.

The charts plotted for the electrical readings, for the month of March, 1900, have been carefully studied for the purpose of this paper. On these charts a dotted line shows the total station output, and a solid line the generator output. The difference in the positions is due to the presence of the storage battery, which causes the dotted line to be above the solid at times and at other times below it. When the dotted is higher the battery is discharging, and vice versa. The area inclosed between the lines shows the amount of battery action, either charge or discharge, the inclosed area being exactly proportional to the energy transferred.

The charts show the following points very clearly:

1. The effect of the battery in straightening the generator load line is evident from a casual glance, the peaks being practically entirely carried by the battery.

2. The storage of energy for emergency use during light loads is shown by the large "charging areas" at these times. At night when the engines are all shut down and the load did not equal the capacity of the rotaries, the battery took up the surplus power. Similarly for the morning hours between the early peak and the noon hour.

3. The great assistance of the battery is adjusting the engines and generators to the changing load is brought out in a very interesting manner. As the load decreased the battery accepted more and more current from the generators, as shown by the battery ammeter. When the current had reached a point, fixed by previous experience, a generator was cut out. This reduced the generator capacity for the time below that required for the load. The battery then discharged until the load had fallen below the capacity of the generators. This continued until all of the generators had been cut out, and yet none had been run at inefficient loads.

By integration of the charge and discharge areas on the chart by means of a planimeter, the input and output of the battery in ampere-hours was obtained. From these measurements it was determined that during thirty-one days the battery received 189,369 ampere-hours, and gave out 164,036 ampere-hours, or a proportion of discharge to charge of 86.6 per cent. This is independent of some minor slight fluctuations too small to be noticed on the chart, but which affect the battery efficiency slightly. Assuming that the difference in pressure at the battery terminals varies by about 12 per cent between average charge and discharge, the efficiency of the battery for the work demanded of it in this case is about 75 per cent. This is lower than would be obtained for regulating work only, the peak or emergency work requiring overcharging with consequent loss of efficiency. In a case where the battery was used largely for regulating purposes with very small variation in voltage, over 90 per cent watt efficiency has been obtained.

4. From the coal records, the fact is deduced that less than 4 lbs. of coal are required for each hp-hour of electrical energy given to the line.

This record system is admirable, and gives data from which not only the performance of the station can be ascertained, but by studying which desirable improvements in equipment and methods of operation can be decided upon.

SIBLEY COLLEGE TESTS

Additional data for studying the operation of the plant under consideration can be obtained from a set of elaborate tests made during several days of March of this year.

The purpose of the tests was to determine:

1. The station economy as a whole.

2. To discover the effectiveness of the storage battery.

3. To determine the relative economy of the power from the engines and from the rotaries.

Incidentally the efficiencies of the various parts of the equipment were necessarily determined.

The standard methods were used throughout and no loss of any moment was allowed to go unmeasured. All instruments were carefully calibrated, and all readings were made continuously for twenty-four hours at very minute intervals. The error in the electrical measurements, as far as the instruments were concerned, was not more than one-half of one per cent, probably less. Particular interest in connection with the subject under discussion attaches to the battery measurements. A large Weston ammeter with plus and minus scale was used for the battery current readings. These were made at twenty second intervals for seventy-two consecutive hours without interruption.

The data resulting from the tests comprises the following:

Complete sets of data relating to all individual parts of the station under three conditions:

1. Normal, that is with generators, rotaries and batteries operating as usual.

2. Without rotaries, that is without Niagara power.

3. Without battery.

The information under these conditions is:

Complete boiler tests, including every detail and computation of boiler and grate efficiency.

Engine indicator diagrams and other measurements for determining engine output and efficiency.

Generator readings of current and pressure.

Battery readings of current and pressure at twenty second intervals.

The tests involved the employment of over eighty observers, and the computations required the labor of a number of men for several months.

The results of the tests are given in the following tables, taken from the thesis of Messrs. Burt and Macomber, and already printed in the *Sibley Journal of Engineering* for June, 1900, in connection with a paper by Profs. R. C. Carpenter and H. J. Ryan.

PARTIAL SUMMARY OF RESULTS OF TESTS

	Run 2	Run 3	Run 3
Pounds of steam per i. h. p. per hour auxiliaries included..	24.88	24.38	25.79
Water from and at 212 degs. in lbs. per e. h. p. hr.....	34.1	33.5	342.
Coal per i. h. p. per hour lbs.	3.53	3.31	3.64
Dry coal per e. h. p. hr. lbs..	4.23	4.04	4.17
Ave. mech. efficiency.....	84.1%	83.7%	84.2%
Engine i. h. p. hrs.....	69,900.	107,700.	53,250.
Generator output, hp-hours..	61,300.	92,600.	46,600.
Battery hp-hours—			
Charge	5,350.	6,100.	....
Discharge	1,950.	1,500.	....
Rotary output hp-hours.....	37,500.	....	31,100.
Total output e. h. p. without rotaries	59,900.	88,000.	46,000.

DISCUSSION OF RESULTS OF TESTS

The data resulting from the tests shows that more steam and more coal are consumed per indicated engine horse-power when the battery is not in operation than when it is. This is due to the increased efficiencies of the moving machinery. The summary shows that the efficiency is slightly less under normal conditions than when operating without the battery, but this is the average efficiency for the whole plant, some parts of which operated for a comparatively small number of hours per day.

The apparent battery efficiency is very low, due to a prolonged over-charging. It has been previously shown that the efficiency of the battery is not far from 75 per cent under normal conditions, and over-charged only to an amount necessary to secure a reserve for emergencies. Unfortunately the cells had been heavily over-charged just previous to the test, on account of some cells which had been short-circuited. Also, at the time of the tests a very heavy snow fall drew so heavily upon the resources of the station that the engineer evidently heavily over-charged in order to be ready for any possible emergency. This accounts for the low efficiency of the battery. The accompanying table shows a history of this over-charge during the days of the tests.

OVERCHARGE OF BATTERY, MARCH 1, 2 AND 3, 1900

Horse-power hours.

The storage battery is not yet perfect, for there are disadvantages connected with its use. There is considerable variation in voltage; its first cost is high; some power must be wasted in the battery. To offset these facts, there is a decided advantage in steadying the load on generators, in keeping up the voltage when the battery is installed away from the station, in enabling the generators to be economically adjusted to the load-line, in wear and tear at the generator commutators on account of the steady load, and, most important of all, in the preparation for emergencies such as peaks in the load-line and possible temporary shut-downs. The remarkably rapid installation of storage batteries in railway stations, which has occurred within the last two or three years shows that the advantages enumerated are generally believed to more than compensate for the disadvantages.

Rochester & Sodus Bay Railway Company*

BY T. J. NICHOLL

At the risk of being called a bore, having a full knowledge of the many descriptions of new electric lines that have appeared from time to time in our railway journals (and which have almost become tiresome), I am going to venture upon your patience with a short description of a new line that has just been completed between the city of Rochester and Sodus Bay, N. Y. I do not know that there is anything particularly unique in its construction, nor that there are any details that may be valuable or even interesting to the convention; at the same time it may be that some points of good can be obtained that will be worthy of your consideration. At all events, the facts are given for what they are worth, and are a record of practical experience.

In 1898 my attention was first called to the necessity of an electric road connecting Rochester with Sodus Bay, between which is located probably the most prosperous country in the State of New York, devoted to agricultural and horticultural pursuits of great variety, the entire distance being 41 miles, and containing a population, including the city of Rochester, of nearly 200,000. This road reaches the famous Glen Haven resort, on Irondequoit Bay, and great Sodus Bay, which has long been noted for its beauty and popularity as a resort.

After many little meetings of a few gentlemen in our city, it was decided to incorporate, and accordingly we obtained a charter

*Paper read before the New York State Street Railway Association. Sept. 18-19, 1900.

on Aug. 13, 1898, after which we had to appear a number of times before the Railroad Commission of the State, and on the 24th of January, 1899, received from the Commission the required certificate, allowing us to proceed with the work. Then came the question of arranging for the money with which to build the road, which occupied our time until about July 1, 1899, when financial matters had been arranged and the real work of getting right of way, making permanent surveys, estimates, etc., began. The first sod was turned on Sept. 11, 1899, and the road was completed Aug. 22, 1900.

ALIGNMENT AND GRADIENTS

The line of the road begins at an intersection with East Main Street in the city of Rochester, 1 9/10 miles east of the center of the city, called the "Four Corners"; thence to Glen Haven, in a northeasterly direction; thence around the end of Irondequoit Bay, crossing the inlets to the same upon what is known as the Float Bridge, and up the Dugway Hill to the west end of the noted Ridge Road; thence along the Ridge Road to the town of Sodus; thence, paralleling the Rome, Watertown & Ogdensburg Railroad, to Wallington, where it passes under the Rome, Watertown & Ogdensburg Railroad in the ravine of Salmon Creek; thence, paralleling the Northern Central Railroad, to the village of Sodus Point on Sodus Bay, being a distance of 39 1/10 miles from the East Main Street station.

The heaviest grade is on the Dugway Hill, where it reaches, in one or two places for short distances, 5 per cent, compensated for curves. There are many other places along the line where the grades are as high as 3 per cent and 4 per cent for short distances, and the shortest curves are of 100-ft. radius. There is level about 70 per cent of the line, and tangents about the same per cent. All of the worst curvatures and gradients are made at the crossing of the Irondequoit Bay, in getting down to and out of the same.

RIGHT OF WAY

About 13 miles of the 39 miles is through private right of way, obtained by purchase and condemnation. The balance is along highways, where we first obtained the consent of the municipalities and afterward of the abutting property owners, and in this respect it may be proper to say that we had any quantity of trouble. The people, feeling that we were compelled to use the roadway, put up all sorts of obstructions and claims for damages, in the way of spoiling trees, crossings, appearance, etc., but I am glad to say that such people were much in the minority. There were sufficient of them, however, to make it very interesting at times. A whole chapter could be written upon this subject alone.

TRACK CONSTRUCTION

Track was built of 60-lb. T rail in the country, and 60-lb. girder rail through the villages, all in 60-ft. lengths; angle plates 24 ins. long, with four bolts 3¾ ins. x ¾ in., and of such a shape as to permit of electric bonding under the same. The rails were laid on oak, chestnut and cedar ties, using the cedar ties, as much as possible, on straight track and oak on curves. At the time the road was built it was quite difficult to get a sufficient number of standard ties, but generally we used ties 6 ins. x 8 ins. x 8 ft. long, and always placed 2-ft. centers. The electrical bonding used was generally a 0000 copper bond about 8 ins. in length, bent and flexible so as to provide for the movement of joint and expansion. In addition to this the track is cross-bonded once in every rail with a 0000 copper wire bond, using a brass clip that is threaded into the web of the rail. The track was ballasted, in many cases, with the local material and filled up well to the top of the rail, but generally with gravel, which had to be hauled some considerable distance from the various points along the line, for which we had to pay all the way from 8 cents to 16 cents per load. On the hills, and where private right of way was purchased, a regular roadway was formed, 12 ft. wide, with banks 12 ft. wide on top and cuttings 16 ft. in the bottom, with ditches, and on such work the track was ballasted with the ordinary material, which was generally sand, and filled only to about 2 ins. above the center of the tie. Along the roadway the general plan was to plow and scrape out to a depth of from 6 ins. to 18 ins., as occasion might require, so as to bring the top of the rail about even with the adjoining highway, and of course in every instance of this kind the track is filled in solid with gravel or equally good material. The bridging is generally of the standard steam railroad, trestle and pile bent style, using both wooden guard rails on the outside of the rails, and rail guard rails on the inside of same, bent inward at the end of the bridges in case of derailment. Along the highways we simply extended the kind of structure used on the highway, as it was needed, which was either of vitrified pipe, brick or stone arches, as the case might be.

The crossing under the Rome, Watertown & Ogdensburg Railroad at Wallington is made through a high embankment, which is now being made by that company, held in position by heavy retaining walls, the Rome, Watertown & Ogdensburg Railroad crossing the same on a solid floor of steel I-beams. The cost of this structure was in the neighborhood of $7,500, and of course was paid for entirely by the electric line, and upon the consent of the Railroad Commission.

In the country the track is generally laid, where not on private right of way, on the side of the road, crossing the same from one side to the other wherever it seemed best and easiest to get the consent of the abutting property owners. Through the villages of West Webster, Webster, Union Hill, Ontario Center, Ontario, Williamson, East Williamson, Sodus and Sodus Point, where girder rail is used, the track is generally in the center of the street.
